**GLASGOW SOUTHERN MEDICAL SOCIETY.**—A meeting of this society was held on Nov. 28th, Dr. John Stewart, the President, being in the chair.—Dr. James Hinshelwood gave an address on Further Observations on Congenital Word-blindness. In introducing the subject of word-blindness the speaker referred to the comparative frequency of the disease, he himself having seen quite a number of cases during the last few months. He thought that they were too apt to think of the eye itself when dealing with the powers of vision in any given case. In order to comprehend the full extent of the visual act they must think also of the relationship of the work of the cerebrum. As an illustration of this close relationship of the eye and the brain he mentioned the result of the operation for congenital cataract. After removal of the cataract the patient, while able to perceive, was for a time unable to recognise, the visual memory not having been developed. In connexion with each special sense there was a memory which developed unconsciously and enabled them to remember past impressions. In some persons these memories were very highly developed and an instance was given of an acute visual memory in which a painter after only once having seen the person could produce a good portrait. In some brain diseases, on the other hand, the patient while able to see with his eyes could not recognise his own relatives. With regard to the anatomical connexion of the auditory, speech, and visual centres in the brain Dr. Hinshelwood showed by means of diagrams that they received their blood-supply from the same artery. A thrombosis might affect one branch of the artery, and should that branch supply the brain area connected with the visual memory for words there would be produced a state of word-blindness, though the eye structures would be found on examination to be quite normal. From a prolonged study of the subject he had come to the conclusion that there were memory centres in the brain for words, figures, and letters; that in man these centres were acquired; that they were present on one side of the brain only; and that they consisted of groups of specially developed cells. On what other theory, he remarked, could be explained those cases in which the memory for words alone was blotted out or where the scholar conversant with many languages became word-deaf to his mother tongue alone? After some remarks on the prognosis of word-blindness he referred to treatment and recommended re-education of the patient in the hope that a corresponding area on the other side of the brain might develop and take up the work. Speaking particularly of congenital word-blindness Dr. Hinshelwood read the notes of two cases seen lately. Both children were very intelligent, could spell, count, and repeat passages by heart, but had great difficulty in learning to read. In the attempt to read both children would repeat aloud the letters of the word, thus making use of their auditory memory centre, which was quite intact. In explaining the causation he thought that there was defective development in the cells of the brain area concerned with the visual memory for words and letters. In conclusion he dwelt on the importance of having these slight brain defects of children recognised and attended to and advocated special classes for backward children.—The address gave rise to some discussion and at the close, on the motion of Dr. John Fraser Orr, Dr. Hinshelwood received the thanks of the society.

**ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND.**—The annual meeting of this society was held on Nov. 29th.—Professor G. B. Howes, the honorary treasurer, in submitting a statement of accounts referred to the healthy financial condition of the society.—The following were elected as officers for the ensuing year: President: Mr. C. B. Lockwood. Vice-Presidents: Mr. R. Clement Lucas, Dr. Arthur Thomson, and Dr. A. M. Paterson. Treasurer: Mr. G. B. Howes. Secretaries: Dr. Peter Thompson (England), Dr. T. H. Bryce (Scotland), and Dr. C. J. Patten (Ireland). Council: Dr. C. Addison, Dr. R. J.

Berry, Dr. A. Birmingham, Dr. J. Black, Dr. D. J. Cunningham, Dr. A. F. Dixon, Dr. E. Fawcett, Dr. W. H. Gaskell, Dr. Robert Howden, Dr. A. Keith, Dr. A. Macalister, Dr. J. Musgrove, Mr. F. G. Parsons, Dr. W. G. Ridewood, Dr. Arthur Robinson, Dr. Barclay Smith, Dr. J. Symington, Mr. G. D. Thane, Dr. A. H. Young, and Dr. B. C. A. Windle. — After Mr. C. B. Lockwood had taken the presidential chair the thanks of the society were given to the outgoing President, Dr. A. H. Young, and to the outgoing secretary for England, Dr. Arthur Keith, for their invaluable services. — The following communications were brought before the society: — Dr. Walter Kidd: Diagrams illustrating the Arrangement of the Hair on the Frontal Region of Man. — Dr. F. H. Thiele (introduced by Mr. G. D. Thane): A Heart showing Transposition of the Aorta and Pulmonary Artery, with complete separation of the Right and Left Ventracles. — Mr. F. W. Jones showed (for Dr. Finlayson) a specimen of Complete Absence of the Left Lung in a Child. — Dr. Hugh Rigby: A curious form of Diaphragmatic Hernia. — Dr. A. Keith and Mr. F. W. Jones: Specimens illustrating the Development of the Cardiac End of the Human Stomach. — Dr. R. J. Gladstone showed some Cephalo-metric Instruments, including (1) an improved form of callipers designed by Mr. J. Gray; (2) an instrument for measuring the distance between the bi-auricular line and bregma; and (3) a machine for drawing the contour of the head.

**CLINICAL SOCIETY OF MANCHESTER.**—A meeting of this society was held on Nov. 19th, Dr. Herbert Lund being in the chair. — Dr. Eugene S. Yonge described Ash's Operation for Deflected Nasal Septum and minutely demonstrated the technique of the operation and the instruments used in its performance. He showed some patients upon whom he had operated with very satisfactory results. — Dr. W. Milligan gave a short demonstration upon the Treatment of Chronic Suppurative Mastoiditis, with special reference to the employment of epithelial grafts as a means of healing the cavity in the bone left by the operation. The demonstration was illustrated by a number of lantern slides, a number of the slides having been lent by Mr. C. A. Ballance. The technique of the operation for removing disease in the bone was fully described and slides were shown to illustrate various points in the anatomy of the mastoid area. The method of grafting, as suggested by Mr. Ballance, was fully dealt with, the various steps of the operative technique being shown upon the screen. Certain of the instruments necessary in the performance of the grafting operation were also shown and reference was made to the electric motor which Dr. Milligan in conjunction with Mr. Ballance had invented. Special stress was laid upon the necessity of clearing out all disease and the difficulties which were encountered in doing so. The method of cutting grafts was also demonstrated and the lining of the cavity with gold leaf was fully illustrated. The results of the operation as a whole were then considered and it was shown how the period of after-treatment was distinctly diminished by the employment of epithelial grafts. Two patients upon whom the operation had been performed were shown to the meeting; and the favourable results to their hearing power were pointed out.

**DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.**—A meeting of this society was held on Nov. 27th, Dr. A. J. Harrison, the President, being in the chair. — The following cases were shown: — Dr. J. H. Stowers: (1) Two cases of Papulo-Squamous Syphilis; (2) Recurrent Psoriasis; (3) a Disorder of the Nails; and (4) Lichen Planus. — Mr. H. Betham Robinson: A case of a Circular Sore with hardened edges involving the inner part of the left eyebrow, with glandular enlargement in the neck. Six months ago the patient had an induration of the frænum which was succeeded by a papular eruption. — In the discussion which followed the question was raised whether the sore was of the nature of an early occurring gumma or of some septic origin in a much debilitated syphilitic subject. — Dr. J. M. H. MacLeod: Chancre of the Lip in a Child, six years of age. — Dr. A. Eddowes: A case of Chancre of the Lip. — Mr. A. Shillitoe: (1) A case of (?) Hypertrophic Scar Tissue (?) Keloid in a man who had previously suffered from severe rupia; and (2) an obstinate case of Psoriasis which had yielded rapidly to copaiba. — Dr. E. Graham Little: (1) A case of Tertiary Syphilis of the Cheek; and (2) a Drawing of a case

of Acanthosis Nigricans. — Dr. E. Stainer: (1) A case of Congenital Linear Papilloma in a child, 17 months old; and (2) Illustration by Diagrams of the Hereditary Transmission of Ichthyosis in two families. — Dr. Wilfrid B. Warde (for Dr. P. Abraham): A case of Bazin's Disease of the Leg. — Dr. A. J. Grant (for Dr. P. Abraham): (1) A Warty Condition of the Lip; and (2) Paraffin Eruption of the Leg.

## Reviews and Notices of Books.

*Alcoholism: a Study in Heredity.* By G. ARCHDALL REID, M.B., C.M., F.R.S. Edin. London: T. Fisher Unwin. 1901. 8vo, pp. 293. Price 6s. net.

SOME years ago<sup>1</sup> we reviewed a book by Dr. Archdall Reid in which he broached the subject of alcohol as a selective agent in the evolution of man. The present volume is an expansion of this theme. In it the author gives a description of certain laws of biology by which alone, he maintains, the phenomenon of national drunkenness can be satisfactorily explained and in obedience to which lies the only hope of reform.

Put shortly, Dr. Reid's argument is as follows. The action of alcohol on the race, he believes, is closely analogous to that of the zymotic diseases. In order to survive in the struggle for existence a nation must acquire a certain power of resisting pathogenic organisms, for they are too widely distributed to be avoided. It can only gain this power by suffering from the diseases till the requisite degree of immunity has been developed; this can never be gained by avoiding them. The nation which has not developed it is liable at any moment, as the means of communication improve, to share the fate of certain savage tribes and to be crippled, or even exterminated, by imported microbes. A study of the history of drunkenness, says the author, shows that the temperate nations, such as the Greeks and the Italians, are those which have passed through a period of drunkenness and have acquired a certain degree of immunity. The most intemperate are native tribes to whom alcohol has only recently been introduced. Between these two come nations such as ours, which are still in their drunkenness stage. The genesis of inebriety in an individual depends upon three factors, one inborn—a capacity for enjoying indulgence in alcohol—and two acquired, firstly a personal experience of the sensations produced by alcohol, and secondly the increased delight in drink which continued indulgence confers. Speaking generally, men indulge in alcohol, or tobacco, or anything else, in proportion to their desire for it. Therefore the people who have the capacity for enjoying drunkenness drink to excess. Those who have not this capacity remain sober, whether they are teetotalers or not. The temperate nations are sober in countries where alcohol is cheap, not because of restrictive legislation but because they have lost the wish to get drunk; or, to speak more accurately, the drunkards, unfitted by their vice to survive in the struggle for existence, have been eliminated, leaving the nation composed of persons who have not the inborn capacity for delighting in alcoholic excess. How this capacity was originally acquired is not known, but having once inherited it an individual cannot get rid of it nor can he avoid transmitting it to his children who in their turn will hand it on, in undiminished strength the author assumes, to his grandchildren, so that in a few generations the predisposition to alcohol of a large section of the community would, through reversion, "gather head till, like an obstructed mountain stream, it burst all barriers, when the last state of the race would be worse than the first."

<sup>1</sup> THE LANCET, June 13th, 1896, p. 1847.

It will be observed that where the author and the "temperance reformers of the dominant school" part company is in their estimate of the relative importance in the genesis of sobriety of the inborn and of the acquired characteristics. The latter have confined their attention to the acquired, the former practically ignores all but the inborn. The two positions are as far apart as the poles and if Dr. Reid is in the right all attempts to hinder those who wish to get drunk from doing so must work the nation incalculable harm, for as the author says plaintively, "Did we abolish drink we could not discover the drunkard," and if he is not discovered how can he be eliminated? The only way in which the devastating career of this particular inborn characteristic can be stayed is by a process of selection, natural or artificial. The former involves an immense amount of misery which may be avoided by adopting the latter. The remedy suggested is to prevent drunkards from having children by the threat of "say, a month's imprisonment."

The author's theory is ingenious and ably advanced and yet it leaves us unconvinced. One objection in the way of our accepting it is the sobriety of Mahomedans. Dr. Reid thinks that they have not been long enough under observation yet for us to know what effect their temperateness may be having upon them, but 1000 or 1200 years have given other people time to undergo great changes in their attitude towards alcohol and if the Mahomedan races are in the position of an obstructed mountain stream the dam would surely by now be showing some signs of yielding. The position of women, about whom the author is silent, is another difficulty. They presumably inherit the capacity for delighting in alcoholic excess equally with the men, and yet with local and temporary exceptions they have always been relatively temperate owing largely to the constant influence of acquired characteristics, and women as a sex give no indication to-day of wishing to burst all the barriers which keep them from drunkenness. In the present state of our knowledge it is impossible to say definitely in what proportion the inborn and the acquired factors are responsible for the genesis of inebriety, for we do not know enough about either of them. We know little of the production of variation and perhaps less of the indirect effect on children of their parents' intemperance. Under these circumstances it seems wiser to follow the line successfully pursued by Mahomedans and women, even if the resulting benefit is only to last a few thousand years, and to learn more of the influence of heredity in alcoholism before taking practical steps in the direction pointed out by the author. Dr. Reid denies that he advocates free drunkenness as a remedy for intemperance, but if there is only one way of discovering who are the unhappy possessors of the inborn characteristic to which we have referred, it would seem only common sense to give everyone an opportunity of showing whether or not he ought to be eliminated. Women especially, if the author's theory is correct, should be afforded every facility for getting drunk. They must, in his eyes, be an appalling source of danger at present!

Although we are far from agreeing with the author on numerous points we have found his book a most interesting contribution to the study of a difficult subject and we commend it to the attention of every man who thinks seriously on the great question of alcoholism.

*Encyclopædia Medica.* Vol. VIII.: Menstruation to Orbit. Edited by D. CHALMERS WATSON, M.B., M.R.C.P. Edin. Edinburgh: William Green and Sons. 1901. Pp. 563.

THE volume under review, which constitutes the eighth of the series, commences with an article on Menstruation by Mr. Christopher Martin, and concludes with one on the subject of Diseases of the Orbit by an anonymous author. Among the more important contributions which fall within

these alphabetical limits are several which belong to the department of neurology. Under the heading of "Nerves" there is a most important contribution which is jointly supplied by Mr. W. Thorburn and Dr. R. T. Williamson. It is divided into several sections which deal respectively with injuries, mono-neuritis, affections of special nerves, tumours, multiple neuritis, and neuralgia. Each of these sections constitutes a complete account, both medical and surgical, of the special subject under discussion. Considering the wide range of matter embraced under these headings and the extensive reference to special literature which so up-to-date an account must necessarily entail the authors are to be congratulated on having completed a masterpiece of condensation and lucid summarisation. In discussing the question of multiple neuritis the authors regard alcohol as the chief factor in the production of the many varieties of this condition, although they make the judicious reservation that the *foens et origo mali* may possibly be some other toxic agent, such as furfural, which may be present in alcoholic beverages as an impurity; but, on the other hand, they suggest that until it has been clearly demonstrated that ethyl alcohol is not the cause of neuritis under such circumstances, it is safer to describe under the name of "alcoholic neuritis" all cases of peripheral neuritis which are clearly traceable to alcoholic indulgence. Under the heading of "Epidemic Neuritis due to Arsenic in Beer" an excellent account is given of the recent epidemic at Manchester. The importance of two or more toxic bodies acting in combination and conducing to peripheral neuritis is strongly emphasised—a possibility which has been more than once suggested in explanation of the apparently paradoxical cases of arsenical poisoning at Manchester. Professor Oppenheim's observations published some 10 years ago are mentioned in this connexion, as also are the more recent publications by Professor Remak. Another excellent article in the domain of neurology is that of Dr. Wilfred J. Harris on the subject of "Occupation Neuroses." We notice, however, that the theories offered in explanation of the pathogeny of these enigmatic diseases do not include that of Edinger ("ersatz theorie")—a strikingly ingenious explanation of a peculiarly difficult problem. Dr. Fletcher Beach supplies some useful observations on the subject of Education of the Mind, though why "education should commence at the age of five and be continued until the child is 18 years old" is most difficult to understand, especially in face of many of the observations which follow and precede. Dr. Beach calls attention to the vital importance of the early education of the special senses and of the muscular movements, and it is difficult to believe that he would wish us to confine this form of education to the arbitrary limits of time which he imposes. The education of the mind is so closely associated with physical development, and the connexion is so ably handled by Dr. Beach, that we strongly recommend to the notice of readers an article which very clearly realises the inseparability of these two subjects. In the article on Obesity we again notice a statement which appears to be perpetuated in one authoritative work after another and which is to the effect that if the regular intake of food exceeds the nutritive requirements of the organism an accumulation of fat will be manifested in the tissues. An accumulation of fat, particularly in pathological degree, as Bouchard has frequently pointed out, is dependent rather on the individual idiosyncrasies of metabolism than on the nature or quantity of the food; in fact, to quote his own words on the subject, "Nous ne possédons pas une pathogénie de l'obésité ou des obésités," and yet time after time this most intricate problem is summarily disposed of in very much the same words as those to which we take exception in this article. Under the title of "Nose" there are 10 separate contributions by nine different authors. Among these articles we regard

that written by Dr. Greville MacDonald as a peculiarly enlightened and philosophic account of the much-vexed question of adenoid vegetations which occlude in a greater or less degree the naso-pharynx of the majority of children who live under the present-day conditions of civilisation. Although by no means confined to individuals with contraction of the superior maxilla its presence among those who suffer from this developmental error is sufficiently marked to necessitate the inclusion of this etiological factor in any comprehensive consideration of the causes which give rise to this condition. Except as regards the special articles to which we have already referred the eighth volume of the *Encyclopædia Medica* cannot be regarded as rising above the general standard of excellence which has so far been maintained with commendable uniformity.

#### LIBRARY TABLE.

*Intuitive Suggestion: a New Theory of the Evolution of Mind.* By J. W. THOMAS, F.I.C., F.C.S., author of "Spiritual Law in the Physical World." London: Longmans, Green, and Co. 1901. Pp. 160, 8vo. Price 3s. 6d. net.—Many observers have been content to accept the theory that the evolution of mind has been, and is, a parallel process with the evolution of the body, as described so ably by Darwin—the theory which has come to be regarded as capable of being described by the term "survival of the fittest." Darwin, Romanes, Spencer, and Haeckel were nearly agreed on the main principles of the theory. Huxley, Mivart, and Quatrefages among others are not so content and seek other explanations of the phenomena of development of mind. The present author, already known to the reading public for his careful investigations, advances herein a theory that the consideration of the "intuitive" faculties of all created things, from inorganic masses up to the most highly organised creature, man, will supply the hitherto missing links in the theories of the evolution of mind. Man parted company with his simian (or other) ancestors owing to the influence of the environment, which led to evolution of moral sense and reason, and, according to the author, these ancestors obtained knowledge of their environment by their "intuitive" capacity. Bats can "see" without eyes and in the dark; other animals, such as the bees, which make mathematically accurate cells, can "know" without cognitive faculties. Lower organisms perform astonishing adaptive acts without any nerve-structure or mental process whatever. "We meet with the weighty fact," wrote Haeckel, "that sense-function is possible without sense-organs, without nerves." According to Mr. Thomas, the influence of environment is to feed and to keep alive by stimulus, and to develop capacities which unfold from within. "Evolution must be the unfolding from within rather than the in-folding from without." This process of unfolding from within is the subject of the work before us, and the author has succeeded in making this abstruse subject fairly interesting. The book is evidently the outcome of a careful study of the subject, and the author has, we think, a good grasp of the whole scientific attitude towards the theories of evolution. We may express a hope that the book will be widely read and criticised by all the thinking men in the profession.

*A Dictionary of Treatment or Therapeutic Index.* By WILLIAM WHITLA, M.A., M.D. R.U.I., Professor of Materia Medica and Therapeutics in Queen's College, Belfast, &c. London: Henry Renshaw. 1901. Pp. 1025.—As we have said in our review on a previous edition of this book,<sup>1</sup> a book which covers so wide a range as the one before us is very difficult to review at one sitting. Most of the work is very good, so good that although it may appear ungracious

we think it better to point out one or two weak spots which we have come across in order that they may be altered in another edition. For instance, on page 37, where the treatment of amenorrhœa is under consideration, Dr. Whitla recommends the use of the constant current. "Beginning with 10 Leclanche cells ..... the current may be increased to 30 cells ultimately." Now the number of cells in use gives absolutely no indication whatever of the strength of the current. Cells vary in size and in power and the resistance of no two patients is the same. In prescribing electricity the number of milliampères which will probably be found useful should always be given. It is true that a few lines further on Dr. Whitla recommends large cells, but this again does not tell how much current will be given off. In the treatment of hæmoptysis we think that ice compresses to the chest wall have very little or no effect. Purgation and morphia are to our minds the sheet anchors for this alarming affection. The section on Valvular Disease is excellent, and we are glad to see that Dr. Whitla recommends blood-letting in cases of a distended right heart with pulmonary embarrassment. The number of formulæ scattered throughout the book will be found of great use, but we may point out that it is not correct to write, "Aque chloroformi ad uncias iv." (p. 703). The same grammatical mistake occurs in many other formulæ, as given by Dr. Whitla. The blemishes to which we have referred are not of any great moment, but so far as we can see the greater part of the book is well written and accurate and therefore they would be better corrected.

*A Treatise on Materia Medica and Therapeutics.* Vol. I. By RAKHALDAS GHOSH, L.M.S., Calcutta University: Lecturer on Materia Medica, Calcutta University Medical School. Calcutta: Hilton and Co. 1901. Pp. 168. Price 2s. 6d.—This little book, besides materia medica proper, contains notes on pharmacy, dispensing, pharmacology, and the administration of drugs: the consideration of toxicology and therapeutics is reserved for another volume. Materia medica, as the author remarks in his preface, is not an attractive subject and for medical men practising in towns a great deal of it is useless; but Mr. Ghosh's little book gives a very clear account of the various drugs and their preparations. The practical pharmacy section contains many useful hints, but surely there is a slip on page 99 where, under the head of Tinctures, Mr. Ghosh says, "Water is the principal solvent." Nearly all tinctures are made with alcohol although a few have some water in addition. But on the whole the book will be found very useful, although of course no one can learn dispensing entirely from a book.

*Practical Science.* By J. H. LEONARD, B.Sc. Lond. London: John Murray. 1901. Price 1s. 6d.—This is an admirable little book and Dr. J. H. Gladstone has contributed a preface. The book assumes no scientific knowledge on the part of the reader and has a chapter on Decimals which is so clear that we handed it over to a reviewer whose knowledge of any form of calculation is, as he himself confesses, next door to nothing. He reported that he never knew before the use of a decimal point or where to put it, but that after reading Mr. Leonard's instructions the difficulty was cleared up. Following the instructions on decimals come notes on measurements, length, surface, volume, and weight. Easy experiments are given and clearly described. The great point of Mr. Leonard's book is that he writes, as do too few instructors, for the absolutely ignorant pupil, and that unfortunate being is the one who is too often not considered. In all the experiments he gives the reason *why*, and in the ordinary daily course of life the average person who performs without knowing it simple chemical or physical experiments never understands the *rationale* for what he does. Ask the average cook *why* fish should be boiled with a handful of salt and in all probability, even if she does boil

<sup>1</sup> THE LANCET, July 16th, 1892, p. 145.

fish like this, she will not know why. Such books as the one before us should be scattered broadcast.

*Transactions of the Epidemiological Society of London.* New Series. Vol. XIX. Session 1899-1900. London: Shaw and Sons. 1900. Pp. 214.—Most of the articles contained in this volume have already appeared more or less fully in the reports of the meetings of the Epidemiological Society printed in our columns. The papers now published in book form are 11 in number, several of them being illustrated by diagrams, maps, and plans. The subjects dealt with are the comparative mortality of English districts, plague, diphtheria and its bacteriology, insanitary property and workmen's dwellings, distribution and control of measles, infectivity of enteric fever, immunity and resistance, and age-distribution of deaths from certain infective diseases. A fine portrait of the late Sir Richard Thorne forms the frontispiece.

*Hausa Notes.* By WALTER R. MILLER, M.R.C.S. Eng., L.R.C.P. Lond. London: Henry Frowde. 1901. Pp. 127.—Mr. Miller is a missionary of the Church Missionary Society, consequently he knows the need for such a book as he has given us. To know the language of the people to whom a missionary wishes to talk is an essential and the times of the Apostles are far distant so that a language nowadays has to be learned. Mr. Miller has transliterated Hausa into English characters and in being able to do so is more fortunate than his predecessors Cyril and Methodius who in evangelising the Bulgarians had to invent an alphabet wherein to write down words. The book seems very clear, although our knowledge of the Hausa tongue is by no means extensive.

*Brown's Madeira and the Canary Islands with the Azores.* By A. SAMLER BROWN. Sixth and revised edition. London: Sampson Low, Marston, and Co., Limited. Cape Town: J. C. Juta and Co. 1901. Pp. 339. Price 2s. 6d.—We cannot add anything to what we have said upon previous occasions about Mr. Brown's book. The fact that it has reached a sixth edition shows its value as well as anything that we can say. The book is packed full of information of the kind which the average traveller wants. There are plenty of maps which are clearly reproduced, and altogether we consider the work a model guide-book.

*Baily's Hunting Directory, 1901-1902.* London: Vinton and Co., Limited. 1901. Pp. 383. Price 5s.—Nowadays the "hunting doctor" is far less common than he used to be, but plenty other members of the community still have the time and the means for hunting; in fact, we fancy that masters of hounds would not be sorry to see smaller fields than they sometimes do see. Hunting men will find all the information they require in the book before us and we can imagine the immortal Jorrocks's delight at the account of the Waterloo run: "My vig, vot a run!"

*Queensland: Report of the Inspector of Hospitals for the Insane for 1900.* Brisbane: G. A. Vaughan. Pp. 13. Price 7d.—This annual report, by Mr. James B. Hogg, shows that on Dec. 31st, 1900, there were 1728 insane persons in the various institutions in Queensland—namely, 693 males and 357 females in the Hospital for the Insane at Goodna, 135 males in that at Ipswich, 270 males and 264 females in that at Toowoomba, and the remainder in three reception houses. The estimated population of Queensland on Dec. 31st, 1900, was 498,249, so that one out of every 288 of this number needed care on the ground of insanity. During 1900 there were 347 admissions, 167 discharges, and 123 deaths.

*Motherhood.* By CHARLES J. GLASSON, M.D. Brux. London: John Bale, Sons, and Danielsson, Limited. 1901. Pp. 91. Price 1s. 6d.—This little work contains a good deal of sound common-sense, clearly and pleasantly put, and should be of value to the young married woman or to the

mother of a family. The most interesting chapter is that on the training of young girls, and if mothers would only follow the advice given by the author they would save their daughters much unhappiness and ill-health. Dr. Glasson utters a timely warning against the tendency to crowd into a few hours of one day physical exercises which should be spread over the whole week. We cannot agree with the author when he forbids cycling for girls of from 14 to 20 years of age. He does not state his reasons, but from what he says we gather that he thinks it likely to produce irritation of the genital organs. We are quite sure that when this does occur it is due to an improperly fitted or improperly placed saddle. If such effects often accompany the use of the bicycle then there is no reason why cycling should be allowed to women over 20 years of age and not to those under that age. Altogether "Motherhood" is a useful little book.

*The Hero.* By WILLIAM SOMERSET MAUGHAM. London: Hutchinson and Co. 1901. Pp. 352. Price 6s.—Mr. Maugham's first book was, we believe, that clever, although very sombre, story, "Liza of Lambeth." In the book now before us the powers of observation which we noted in his first book are equally present, but his characters are concerned with higher mental processes than were 'Liza and her friends, for the most part. We are not so sure as is Mr. Maugham of the correctness of the title, for we take leave to doubt whether suicide as a means of getting oneself out of a difficulty is heroic. All the same, the occurrence was supposed to be accidental, so James Parsons spared his father and mother the sorrow of knowing that he had taken his own life. However, the ethics of suicide form a difficult question. Mr. Maugham writes feelingly about district visitors. There are some who would have tried the patience and gentleness of St. Francis of Assisi, and such a one was Mary. Chapter VI. is an admirable exposition of her methods, and the scene with Dr. Higgins over a bottle of port is excellent reading. Altogether we congratulate Mr. Maugham.

*Sell's Dictionary of the World's Press.* London: Henry Sell. Pp. 948. Price 7s. 6d.—"With the issue for 1901 Sell's Dictionary of the World's Press celebrates its coming of age and the commencement of a new century. No pains have been spared in making the book worthy of the double event." So runs the preface, and a perusal of the book will demonstrate the truth of the latter statement. As a complete record of the world's press arranged for easy reference this "dictionary" takes a leading place, and no more useful book can be found for professional men and commercial establishments. In addition to the newspaper and magazine lists there are to be found articles of interest to everyone. Among them we may mention "Newspapers of the New Century," "Journalism and the South African War," "The Young Journalist's Library," "Parliaments of the British Empire" (with illustrations of 20 Parliament houses), and "British Journalism a Hundred Years Ago." In this last article it is pointed out that in 1800 there were no daily journals published outside London in England, Wales, or Scotland, and that the total number of news issues was then only about 250 as compared with about 2500 at the present day. It is interesting to note that a century ago there were no sensational head-lines such as we have now for the benefit of the vociferous proclivities of the newsboy and the general annoyance of the public, but our predecessors had occasionally to contend with something perhaps even worse, for "the London newsmen were equipped with trumpets, and it was their custom to rush along the streets blowing these and shouting 'Great news,' 'Glorious news,' or 'Great British victory,' as the case might be." A portrait of Her late Majesty Queen Victoria adorns the commencement of the book, and there are many portraits of editors and others

connected with the literary profession scattered throughout the text.

*Handy Newspaper List.* London: Charles and Edwin Layton. Pp. 168. Price 6d.—This is a convenient little reference-book containing information about the newspapers, magazines, and other periodicals published in the United Kingdom, including the price of the journals, date of establishment, politics or class, and the address of the publishers. All the towns in the United Kingdom in which newspapers and periodicals are published are arranged in alphabetical order with the exception of London, which on account of its great importance as a publishing centre is placed first on the list. Whether for private use or for commercial purposes the book will be found to justify its title both as regards size and the concise and accurate manner in which the information is given.

#### JOURNALS AND MAGAZINES.

*Medical Magazine.*—The November number contains an interesting lecture by Sir Samuel Wilks on the Importance of Having a History of Diseases. By several very *a propos* instances the author shows how often a knowledge of the history of an individual disease may save repetition of former work the result of which has been neglected, and may prevent mistaken notions as to the novelty of a malady and as to the early investigators by whom its symptoms were elucidated. Sir Samuel Wilks's own work in connexion with the supposed association of leucoderma and Addison's disease affords a striking example of the need for accurate historical knowledge in medicine. Sir Samuel Wilks makes some instructive comments upon the history of small-pox and its treatment by inoculation and later by vaccination, pointing out that cow-pox, though strictly comparable with the inoculated form of small-pox, is certainly not so with the ordinarily acquired form. Other articles deal with the present position of the midwives question and with army medical reform. Dr. W. H. Allchin continues his description of the reconstruction of the University of London. What the labours must be of those engaged upon a reconstruction the mere history of which is so interminable we shrink from imagining. An article upon the Medicine and Doctors of Horace with the Public Health and Foreign sections complete the number.

### New Inventions.

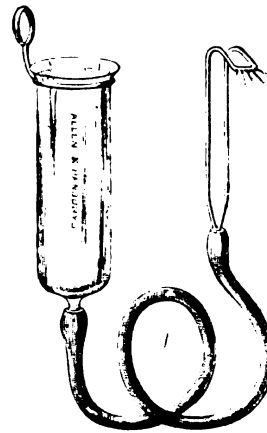

#### SAFETY EYE IRRIGATOR.

THE treatment of contagious disorders of the eye has often proved disastrous to both surgeons and nurses, and many instances have occurred of serious injury and loss of sight; now this little contrivance has been designed to give protection to the operator and also to secure rapid and thorough irrigation of the conjunctival sac. It discharges a double current of lotion with sufficient force completely to cleanse the eye without any risk of splashing and scattering the dangerous secretions. The instrument consists of two metal tubes which are bent at an acute angle at one extremity and united by a short tube which is perforated with several holes on the convex edge; at the other extremity they are joined together and form a short tube to which the indiarubber tube of the glass receiver is attached (see Fig. 1).

*Directions for use.*—The irrigator must first be carefully introduced under the upper lid and then held between the thumb and finger of the left hand and the lid gently elevated; at the same time the right hand raises the glass receiver containing the lotion. The full stream caused by the double current quickly washes out the upper palpebral sinus. The

irrigator should then be removed and introduced under the lower lid and the washing repeated. The waste fluid can be conveniently collected in a small bowl placed on the side of

FIG. 1.

the patient's head. In cases of contagious ophthalmia the sound eye must be protected by an aseptic pad during the operation. (Fig. 2.)

FIG. 2.

The instrument has been neatly made for me by Messrs. Allen and Hanburys, Limited, and with it compressed discs of sulphate of zinc, nitrate of silver, perchloride of mercury, boric acid, and sulphate of alum can be obtained ready for immediate use.

JOHN WARD COUSINS, M.D. Lond., F.R.C.S. Eng.,  
Senior Surgeon to the Royal Portsmouth Hospital and the Portsmouth and South Hants Eye and Ear Infirmary.

**SMALL-POX AT WARMINSTER.**—At a special meeting of the Warminster Town Council held on Nov. 26th the medical officer of health reported that four cases of small-pox had occurred at Warminster, two of which had terminated fatally. The first case occurred some weeks ago, the patient being a tramp who had journeyed from London. The council have secured a farm-house for the purpose of isolation.

**MEDICAL CERTIFICATES FOR SCHOOL BOARDS.**—At the meeting of the Merthyr Tydvil School Board held on Nov. 22nd the School Attendance Committee reported that they had received an endorsement by a medical man written on one of their notices to a parent respecting a child's attendance: "Unfit to attend school." When written to inquiring the nature of the unfitness a reply was received stating that on receipt of a fee the information would be given. Several members commented upon the "curtness" of the reply, but it certainly would be more satisfactory if the Merthyr School Board made some remuneration for these certificates.

# THE LANCET.

LONDON: SATURDAY, DECEMBER 7, 1901.

## Medical Aid Societies and the General Medical Council.

A CASE of great importance both to the medical profession and to those societies which employ contract medical aid was temporarily adjudicated upon by the General Medical Council on Nov. 29th. The facts of the case, which are set out in detail in our report of the proceedings of the Council, were as follows. Mr. ROBERT RENDALL, M.B., C.M. Edin., was summoned to appear before the Council to answer the following charge as formulated by the Council's solicitor: "That you have been guilty of infamous conduct in a professional respect, particulars of which are that you have accepted and continue to hold the appointment of medical officer to the Liverpool Victoria Legal Friendly Society at Great Yarmouth, a society which systematically practises canvassing for the purpose of procuring patients, and that you have approved or acquiesced in such canvassing." The complainants were the Medical Defence Union, acting on behalf of local members of the union, for whom Dr. A. G. BATEMAN appeared, while Dr. RENDALL was represented by Mr. LAWSON WALTON, K.C., M.P., and Mr. C. MATTHEWS. Dr. BATEMAN, in opening the case, reminded the Council of the resolution passed by themselves in June, 1899, which ran as follows:—

"That the Council strongly disapprove of medical practitioners associating themselves with medical aid associations in which systematic canvassing and advertising for the purpose of procuring patients are practised."

Persons, he said, were undoubtedly canvassed by agents of the Liverpool Victoria Legal Friendly Society, and these agents also canvassed for the National Medical Aid Company. Dr. BATEMAN called witnesses and put in statutory declarations to prove this point. On the other hand, various collectors, both past and present, of the friendly society gave evidence that they had never canvassed for the medical aid company and had been strictly forbidden to do so. Eventually the Council decided that the points mentioned in the notice of inquiry had been proved against Dr. RENDALL and gave him until next session to consider his position. This result was a great forensic triumph for Dr. BATEMAN who secured a victory for the Medical Defence Union against the capable pleading of two famous advocates. We congratulate him heartily upon the manner in which he conducted the case for the Medical Defence Union, and the Union for taking up and fighting a most important cause.

We are glad to see that the Council took the line that they did. We cordially approve of the conclusion to which they came, while the delay in imposing a penalty upon

Dr. RENDALL is proper. The case is in the nature of a test case and should not be unduly hurried to a definite decision. The case of medical aid societies is always a hard one with which to deal, and this particular instance is rendered all the more difficult by reason of the remarkable relations which exist between the Liverpool Victoria Legal Friendly Society and the National Medical Aid Company. The friendly society, according to its published rules, is simply a society for enabling persons by means of a weekly or monthly payment "to insure a sum of money on the death of a member, or child of a member, or an endowment upon either attaining a certain age." In other words, it is an insurance society and nothing more. On inquiry at the head office of the society we were informed that they had nothing whatever to do with the National Medical Aid Company. Concerning the accuracy of the information we were, however, a little sceptical. Our Special Commissioner, when making his inquiries for our articles upon the "Battle of the Clubs," found that the canvassers of the Liverpool Victoria Legal Friendly Society, when canvassing for membership of that society, were in the habit of opening negotiations by pointing out the advantage of paying 1*d.* per week to the National Medical Aid Company so as to secure the advantages of the medical man employed by that society. We were not, therefore, much surprised when, on inquiry at the offices of the medical aid company, we were told that every member of the medical aid company must be a member of the Liverpool Victoria Legal Friendly Society, and that no one who was not a member of that society could be a member of the medical aid company. This statement, however, is directly at variance with that of Mr. PETERS, an official of both the society and the company, who stated, in answer to Sir WILLIAM THOMSON, that any person could be a member of the medical aid company although not insured in the Liverpool Victoria Legal Friendly Society. The collectors for the one society, we were also told, worked for the other. Mr. CULLY, who gave evidence, was a district manager of both the friendly society and of the medical aid company, while Mr. PETERS, in his evidence, stated that he was chief clerk of the friendly society and also a director of the medical aid company. There would seem, therefore, to be a pretty close union between the two societies, if not, strictly speaking, an official union. And, in fact, Mr. LAWSON WALTON in his reply implied that the staffs of the two societies were connected. "It had been suggested," he is reported as saying, "that all difficulties would be avoided in future if there were a separation in the staff of the friendly society and the medical aid society, but he was informed that if such a separation took place it would not be worth the while of the medical aid society to organise a staff of its own, and that it would be better to let it die out." It seems, then, that Dr. RENDALL'S position was that of a medical referee to the Liverpool Victoria Legal Friendly Society and that incidentally the collectors of that society were accustomed to point out that Dr. RENDALL'S club—i.e., the medical aid company—was an advantageous body to join. The Council considered that they had evidence before them to prove that Dr. RENDALL was associated with an institution where systematic canvassing was carried on

and gave effect to the resolution of disapproval which they had passed in June, 1899.

The action of the Council in this test case is of far-reaching importance. We disclaim at the outset the idea that it is necessarily disgraceful for a medical man to belong to a medical aid society. But he must not work for a medical aid society which, under the guise of philanthropy, exploits the labours of medical men to whom it pays an insufficient salary. The medical aid society, as a rule, collects a large number of pennies and half-pennies from the poor, supplies them with a medical man who is always underpaid and generally overworked, and pockets any surplusage over the medical man's salary. As far as the medical aid society is concerned the position is not immoral, it is a purely commercial speculation; but the position of a medical man to such a society is altogether unenviable. Dr. RENDALL has some six months before him wherein to consider his position. We trust that he will come to the conclusion to bring himself into line with professional opinion and will cut himself off from all communication with a lay association which requires him to work in opposition to accepted medical ethics. We may have occasion to recur to this case, the importance of which is fully recognised by all parties concerned.

### The Annual Meeting of the Fellows and Members of the Royal College of Surgeons of England.

It cannot be said that any very important incidents occurred at the seventeenth annual meeting of the Fellows and Members of the Royal College of Surgeons of England, and yet the occasion was by no means devoid of interest. The attendance was decidedly small; less than 50 Members were present. Here and there a Fellow could be seen, while in the well of the theatre sat the President, the two Vice-Presidents, and two or three other members of the Council. This apathy on the part of the Members of the College is probably only apparent. It is hopeless to expect many Members living in the country to come up to such a meeting, and of those in London but few have the necessary leisure. Moreover, we cannot help thinking that many of the Members have begun to despair of ever obtaining their rights. This attitude is very comprehensible, but it is wrong. One of the greatest arguments in favour of the Members' claims would be to show that they really take an interest in the College and wish to share in its government. The Members should attend in their hundreds; the two or three hours required once a year could be spared by most men, even by those with very large practices.

The President (Mr. H. G. HOWSE), in presenting the report, pointed out two changes that had been made in connexion with the report in consequence of resolutions carried at the last annual meeting. Formerly the report was sent to all the Fellows and to those Members who chose to apply for it. Now the Fellows and Members are put on the same footing and it is sent to all who apply for it, and the names are placed on a permanent list so that it is not necessary to make a fresh application every year. The large number

of Members who have applied for a copy shows that many of them are interested in the College. The other change is the inclusion in the report of the names of those Members who have died during the past academical year. These names occupy eight pages and we obtain some idea of the proportions of the Membership of the College when we find that one year's loss includes 450 names. The Members are nearly 18,000 in number, and it is absurd that so numerous a body of educated men should have no share in the management of the College of which they are the *alumni*. The time-honoured motion in favour of the participation of the Members in the election of the Council was modified somewhat this year by the introduction of an appeal to the Council to suggest some way by which the Members might be admitted to a share in the direction of the affairs of the College. Time after time a motion has been carried to the effect that the claims of the Members are founded on justice, but no result has followed. The variant brought forward this year will meet, we fear, with no happier fate, but we may hope that time, the solver of all difficulties, will ultimately grant to the Members that for which they have for many years so earnestly striven. We commend this resolution to the careful consideration of the Council. Surely there are in that body a sufficient number of liberal-minded men to bring forward and carry through some measure of relief to the crying wants of the Members.

A motion brought forward by Dr. G. DANFORD THOMAS constituted another important piece of business. At the last annual meeting he had proposed a motion asking the Council to initiate some medical reforms, and in subsequent correspondence he had pointed out some of the more urgent of these. The Council had, after consideration, expressed its inability to take any steps in the matter. Since then a Medical Reform Bill has been drawn up by the British Medical Association, and Dr. DANFORD THOMAS asked the Council to give its hearty support to this Bill. A medical coroner is more than most other medical men in a position to recognise what changes in medical legislation are desirable. He sees many of the more gross instances of the harmful results which follow from the present state of the law, and we therefore consider the alterations suggested by Dr. DANFORD THOMAS to be of peculiar value and importance. Never before in the history of this country has quackery been so rampant as at the present day. The newspapers—not only the cheap and inferior press but organs of recognised influence and importance—contain whole pages of advertisements of safe cures, blood mixtures, and pills. Claims the most exorbitant, statements the most absurd are made, and the deluded public lose alike their money and their health, or even their lives, in the hopeless attempt to cure themselves. Without expressing now an opinion on a large matter such as the Bill already mentioned we may hope that the Council of the College may see its way to support the cause of reform of the Medical Acts. The President promised that he would bring the matter before the Council, and said that he was sure that the Council would consider earnestly the whole subject. We trust that the deliberations of the Council will result in action. The matter is urgent and quite enough abstract resolutions have been passed. The Royal College of

Surgeons of England might well make a representation to the Government.

The appointment of the representative of the College on the General Medical Council was also brought forward and it was suggested that the representative should be appointed by the Fellows and senior Members. We believe that legally it is quite within the power of the Council to assign the real election to this post to the persons suggested, reserving to itself the power of confirming the appointment. It would be a graceful concession and we cannot see that any harm could result. Of course, as the President pointed out, it would be absolutely necessary that the representative should be a member of the Council, otherwise the close connexion which is essential between the opinions of the Council and the action of the representative would be impossible; and it would be very easy to restrict the choice to the members of the Council. Two other motions were brought forward. One expressed regret that the Council of the College had not fallen in with the wish of the General Medical Council to allow the latter Council to determine what institutions should be capable of granting certificates of attendance in elementary science for the first examination for the Conjoint Board. The President stated that the Council had been influenced solely by a desire not to surrender without sufficient reason the rights of the College. The last motion was to the effect that strangers should be admissible to the gallery. We cannot see that there is any great reason against the adoption of this course, as there is no disposition to keep secret the proceedings of the meeting. Reporters are admitted and reports appear in THE LANCET and other medical journals. The motion was, however, lost by 8 votes to 7, and therefore we may conclude that there is no active desire for any such change.

In conclusion we may express again the opinion that the Members are nearing the consummation of their hopes, though exactly how soon the goal may be won none can say. We consider that the Council would be wise to devote immediate attention to the question of the representation of the Members. Surely it can be done without imperilling the stability of the College; it can be done without harming in the least medical education or examination—nay, rather it would strengthen the Council and it would add to the stability of the College to secure the hearty coöperation of that large body of men who possess the Membership of the Royal College of Surgeons of England. The Members must, for their part, not lose heart.

## The Sanitary Administration of the Metropolis.

EVEN as London is unique in the excellence of its isolation accommodation, so, too, it is peculiar in the matter of its sanitary administration. The metropolitan medical officer of health has withheld from him some of the interests which his provincial *confrère* enjoys. Here in London he finds that the water which supplies his district comes from sources over which he has no control and passes through filter-beds to which he has no right of entry. So, also, are the infectious

sick removed in ambulances which have no concern with the local sanitary authority to hospitals of which the medical officer of health has, perhaps, never seen the exterior. In other ways, too, administration overlaps, and hence the medical officer of health finds when he takes his pen to write his annual report that there are several interesting subjects connected with the public health which he is not in a position to discuss in a detailed manner. In a minor degree this dual, or even triple, administrative overlapping affects the sanitary inspector. It is for these reasons that it is difficult to compare the sanitary administration of the metropolitan boroughs with that of the large provincial towns. Moreover, the repeated alterations in the matter of London government renders it impossible to compare the London of yesterday with that of to-day. Mr. SHIRLEY MURPHY has felt this difficulty in dealing with a return as to the administrative staff of the several metropolitan boroughs which has recently been issued by the London County Council. Nevertheless, the return is of much interest, and from it we learn that, exclusive of the staff of the London County Council and of the Metropolitan Asylums Board, London, at the date of the return, was administered in a sanitary sense by 29 medical officers of health and 275 sanitary inspectors. It has, however, to be stated that this latter number does not include the clerical staff or the assistants to the inspectors. Both these facts must be borne in mind in any comparison between the several districts.

Taking first the medical officer of health we find that in the matter of time and remuneration there is a want of uniformity. On the one hand we have the City of London, with a night population of 26,897, engaging the whole-time services of a medical officer of health for £1000 per annum—and no one can reasonably contend that the City should not possess a whole-time medical officer—and, on the other hand, we have the borough of Islington, with a population of 334,928, engaging a whole-time officer for £800. Again, Chelsea, with a population of 73,856, pays £500 a year for a part-time officer; while Holborn, with a population of 59,390, considers a whole-time officer necessary and pays him £700 per annum. Again, Bethnal Green, with a population of 129,681, thinks that the work of its district does not require the whole time of a medical officer of health, and the Council gets rid of its responsibilities by paying £300 to a part-time officer. Paddington, with a population of 143,954, expects the whole time of its medical officer of health for £600. Here, then, are some rather pronounced anomalies which may usefully be remedied in the near future. It is unreasonable to suppose that a medical officer of health who is compelled to reside in London can properly maintain his position on £600 a year. The statutes are yearly imposing additional duties upon these officers, and each year the position which medical officers of health occupy is becoming of more public consequence. The Local Government Board has, we believe, endeavoured to fix £600 as the minimum limit for a whole-time medical officer of health in London, and, although they have succeeded in several instances, they have not yet brought about whole-time appointments in all cases where such appointments are obviously necessary.

As regards the sanitary inspectors, it is difficult to

make comparisons without more particulars than are forthcoming. There are, however, indications that a decided improvement is taking place. When, for instance, the figures for 1898 are, where comparable, compared with those of 1901 it is found that in the majority of districts there has been an increase in the number of inspectors; and in some this augmentation has been very substantial. Mention may be made of Kensington which has set an excellent example by engaging six additional inspectors, and of Southwark where five have been added. Westminster, however, shows a falling off, as also does Battersea. The population to each inspector varies from one to 1921 in the City of London (where, however, it has to be noted that seven of the inspectors are concerned with meat inspection alone) to one to 25,623 in Stoke Newington, one to 23,992 in Paddington, and one to 23,221 in Lambeth. As a general rule the population to each inspector is smaller now than in 1898, and it would seem that female inspectors are being employed considerably more than heretofore. But before accurate comparison can be made with respect to the staff of the several districts it is necessary to know precisely how the work is apportioned. The average population to each inspector is apt to be misleading, as may be seen by a reference to Hammersmith with a population of 112,245, where the average is given at one inspector for 14,031 people. But it would seem that in point of fact the whole population is distributed among four inspectors. The remaining inspectors are engaged in special work of one or another variety. However, it is gratifying to learn that the tendency generally is in the right direction, and much of this improvement is doubtless due to the inspections and reports made by the medical officer and assistant medical officers of the London County Council. The inspection of Kensington in 1899 has not improbably had some influence in hastening on the excellent results to which reference has already been made.

### Sir William Mac Cormac.

THE information of the sudden death of Sir WILLIAM MACCORMAC at Bath on Wednesday morning was received with considerable astonishment by the public, both medical and lay, but those who were well informed of the state of the deceased surgeon's health were not so entirely unprepared as those who had not seen him lately and whose recollections of him were chiefly based upon his commanding appearance at public functions not many months ago. In another part of the paper we give a full biographical notice of Sir WILLIAM MACCORMAC'S interesting and successful career. He will long be remembered among his generation of surgeons, his numerous official positions keeping his striking personality ever in the public eye. He was a sound and bold surgeon, much trusted in high places, whose dignified presence did justice to an extraordinary list of honours. Sir WILLIAM MACCORMAC had reached an age at which a man has earned a right to leisure when the needs of his country took him to South Africa as consulting civil surgeon to the South African forces. The arduous work that he then undertook was chronicled in our columns, his regular reports of the surgery of the campaign being eagerly looked for by our

readers. It seems undoubted that his services to his country are largely responsible for his death. Although he had had one or two severe illnesses notably he suffered some few years ago from empyema he was in sound health when, at the age of 64 years, he went out to the seat of war. There he contracted dysentery and since his return it was noticed by his friends that his loss of vitality was marked. The weakness and depression lately became much increased, and on Monday he went to Bath to see whether hot mineral baths would give him relief from his most painful symptoms—insomnia and vague pains in the loins and back. He had a bath on Tuesday, and appears to have derived benefit from it; but on the following morning he died suddenly from cardiac failure.

### Annotations.

"Ne quid nimis."

#### THE NEW PRESIDENT OF ST. BARTHOLOMEW'S HOSPITAL.

THE ancient foundation of St. Bartholomew's Hospital has once more a Prince of Wales for its President, and the ceremony of installation took place on Dec. 3rd. It was held in the Great Hall, and among those present were the Lord Mayor, Alderman Dr. T. B. Crosby, and several other members of the Court of Aldermen. Sir Trevor Lawrence, in introducing the new President, spoke of the past history of the hospital and referred to the great interest which the late President, now His Majesty the King, had always taken in the work of the institution. The two charges, that of Governor and of President respectively, were then read to His Royal Highness, and he, having taken the Presidential chair, made a suitable reply. It is right that no break should occur in the royal traditions of St. Bartholomew's Hospital, for the foundation has always been connected with the Crown.

#### THE PAY OF CIVIL SURGEONS.

THE civil surgeons who patriotically and gallantly volunteered to help Government in its time of need have not been treated with decent liberality. They were prepared, and doubtless anxious, to serve at the front, but it was thought better to retain them at home and thus liberate trained military officers for active duty in the field. The men who came forward in our national emergency are all qualified practitioners of some standing, while many amongst them are holders of the higher degrees and diplomas which in civil life generally ensure pecuniary advantage. The rate of pay allotted to them by Government appears to us to be totally inadequate, being, in fact a little less than that of a junior army medical officer, who, in addition, is entitled either to a gratuity after some years' service or else to a pension for life. We prefer not to enter upon the invidious subject of the pay allotted to officers of other departments. On their own merits, and quite irrespective of adventitious circumstances, the gentlemen now acting in the place of commissioned officers in the United Kingdom are clearly entitled to increased remuneration. They should be paid in proportion to not only their own professional standing but also in proportion to the pay of the officials whose peace-time appointments they are filling. It seems perfectly clear, also, that civil surgeons employed under the War Department for home duty are entitled to the gratuity specified in Army

Order 136 of June, 1901. It is indeed difficult to understand how the money can be withheld from them, for they certainly come under the head of "civilians appointed to military positions." The action of the Secretary of State for War in refusing to allow this gratuity appears to us to be distinctly arbitrary. He assigns no reason for adjudging the civil surgeons "not eligible," but simply says he "has decided." Unquestionably this withholdment is incompatible with the spirit of Army Order 136. There has been a considerable amount of correspondence on this subject in the public press, but, unfortunately, the prevailing tone was not all that could be desired. There is nothing to be gained in such a case by the adoption of a would-be satirical style. On the contrary, it has a tendency to irritate "the authorities" who, after all, are merely men of like passions with the satirists. Apart from higher considerations, it is a mistake in seeking a boon to try to hurt the feelings of the person who has the conferring of it.

#### EIGHTEENTH-CENTURY REMEDIES FOR CANCER.

WITH regard to an annotation which recently appeared upon the traditional and mediæval therapeutics of the violet a correspondent has written to us pointing out that when the medicinal powers of the violet were most believed in it was never considered to be a cure for cancer. "The sovereign charm," he writes, "for that worst of human ills was the morel, a species of fungus said to be of Italian origin. Human milk, too, honey, and new bread, were ingredients in the plasters laid by forgotten leeches upon growths most probably non-cancerous, but suspected of malignancy in their action or developments. The human milk is, of course, a manifest survival of tribal cannibalistic ideas. It was still recommended among the ingredients of a 'precious medicine' which 'will bring forth a cancer, and pluck it up by the roots' in a popular chapbook of the date 1791. It is curious to note, when tracing the evolution of a recipe from such a book as this through such works as Sendall's MS. of the Commonwealth era to the early writers in Henslow's book, how persistently the mere ritual of the so-called cure survives when the components of the emplastrum or pill have changed half a dozen times. Morel gives place to the white of an egg, and both are now merged in a decoction of violet leaves, but the milk 'of one that hath been a mayde and hath given birth to a knave' is recommended at the dawn of the nineteenth century, while the directions as to the use of lint, a form of bandage rarely, if ever, mentioned in chapbooks, survive from the days of Rufus to the opening years of a new era of enlightenment. The ancient belief was that the lint or cloth, laid upon the growth, would bring it away 'in the morning.' 'In the morning thou shalt find the Cancer dead on the said plaister. This is most true. I copied this out of an old written book.' Nowadays there is no talk of growths being brought away in the night, but none the less the lint is used and the symptoms of the disease are recorded as vanishing in 14 days."

#### GLASGOW UNIVERSITY CLUB, LONDON.

THE autumn dinner of the Glasgow University Club, London, was held in the Hotel Cecil on Nov. 28th, Dr. George A. Heron presiding. About 70 members and guests were present, including Professor J. M. Thomson, F.R.S., Professor Cormack, the Hon. Charles Rothschild, Mr. Gilbert Heron, and Professor C. R. C. Tichborne. Dr. C. O. Hawthorne, one of the secretaries, read letters regretting inability to attend which had been received from Lord Kelvin; Sir William Gairdner; the Rev. Dr. Story, Principal of the University; Professor James Dewar, of the Royal Institution; Mr. J. A. Campbell, M.P. for the Universities of Glasgow and Aberdeen; and from the Secretary of the Carnegie Trust. The loyal toasts having been

duly honoured Dr. Heron proposed the toast of "The Club" in an eloquent speech, the interest of which was enhanced by an outline of the founding and early history of the association. It originated, he said, in 1886. At that time there was already in London a Glasgow and Aberdeen Universities Club, but the number of graduates of each university seemed to be sufficient to justify a separation. Dr. Heron accordingly suggested this course to several of his acquaintances, first consulting the late Dr. John Chalmers and Dr. David Finlay, now the professor of practice of medicine in Aberdeen University. The scheme was favourably received, and in the result a meeting was held in Dr. Heron's house, and the club, which had been a success from the commencement, was then founded. At the first dinner Lord Kelvin was in the chair and the company had the unusual experience of hearing seven speakers reply to the toast of "The Club." Dr. Heron, in concluding, spoke of the beneficial effect which Mr. Carnegie's gift would have on the Scottish universities. The toast of "The Scottish Universities" was proposed by Sir Christopher Nixon (Dublin) and acknowledged by Sir J. Batty Tuke, M.P. for the Universities of Edinburgh and St. Andrews; that of "The Guests" was proposed by Dr. D. C. McVail and acknowledged by Sir James Crichton Browne; and "The Chairman" was proposed by Mr. J. R. McIlwraith.

#### FOREIGN PRACTITIONERS IN CAPE COLONY.

THE Colonial Medical Council of Cape Colony, at a recent meeting at Cape Town, passed by a large majority of those present a motion to amend the regulations governing the admission of foreigners to practise in the colony by the introduction of a new regulation: "That no diploma granted by the Government or any university or other body of a foreign country shall entitle the holder thereof to registration as a medical practitioner or dentist in this colony unless equal rights and advantages are given in such country to the holder of any British registrable degree." An amendment to the effect that the Government should rather be approached and requested by diplomatic intervention to endeavour to achieve reciprocity was lost. The motion and the amendment were respectively proposed by Dr. A. J. Gregory, medical officer of health of the colony, and Mr. J. H. M. Beck, M.L.A., and considerable discussion took place before the original motion was carried. The new regulation now awaits the sanction of the Governor of the colony, and should it secure his approval a step of some importance will have been taken in the interests of medical men with British qualifications practising in Cape Colony. It is quite possible that the establishment of a regulation such as that quoted throughout all British colonies might result in the establishment of a reciprocity which would be warmly welcomed in place of the unequal conditions at present prevailing, where British colonies admit foreign medical men to practice. The nature of these conditions, which naturally are conspicuous in South Africa where British possessions are immediately bounded by those of other European nations, was illustrated at the discussion which took place in the Medical Council of Cape Colony. It was pointed out, for example, that medical practitioners registrable in Cape Colony could not practise in German Damaraland, and that on the Crocodile river, close to Portuguese territory, the Portuguese medical man could practise on the English side, while the English practitioner had to confine his practice to his own colony. Naturally inequalities of this kind are extremely galling, particularly when the foreign practitioner may be regarded as a person not altogether loyal to British rule and friendly towards his English colleagues, while apart from such political questions, with which we do not pretend to concern ourselves

here, the foreign diplomas upon which the foreign practitioner claims registration may not, and in many instances do not, represent the same degree of professional training and tested skill that is implied by the diplomas granted by examining bodies in Great Britain. The proposed regulation is apparently intended to be supplementary to the rules already existing in Cape Colony as to the admission of foreigners to practise there. Its immediate aim is to exclude foreigners qualified under these rules from medical practice in Cape Colony as long as British practitioners are excluded from practice in colonies of the country to which the foreigners belong, or, let us say, in foreign colonies situate in South Africa. We gather that the exclusion desired in Cape Colony already exists in Natal, but that the precise attitude of the profession in Rhodesia was not known at the meeting at Cape Town, while Orange River Colony and the Transvaal have yet to be reckoned with. In these circumstances it seems to us that the regulation proposed in Cape Colony may have important local effects in the exclusion of foreign practitioners, but that the establishment of the reciprocity suggested, even locally, between British colonies in South Africa and foreign colonies that impinge upon them, must of necessity be for some time delayed, while it is not likely to take place without the diplomatic intervention suggested in the lost amendment to which we have referred. That such reciprocity should soon become general between all British colonies and those of any other nation or nations seems to us highly unlikely, while we are not sure that it would be desirable. British practitioners would have more to lose than to gain, and the standard of medical practice in those colonies which now exclude foreigners would not be raised. There is, however, obvious justice in the protest of the British practitioners in Cape Colony against the admission of foreigners to compete with them without any corresponding privilege being granted in return, and we shall look with interest to see the way in which the Governor deals with the matter. There is no doubt a large foreign element to be considered in Cape Colony, but on the other hand, in foreign colonies there are usually large numbers of British residents who would be glad to be attended by their compatriots, but who have to submit to seeing them excluded.

#### INTERMITTENT HYDRARTHROSIS.

THE *Boston Medical and Surgical Journal* of Oct. 31st contains a report of two cases of this curious and little-understood condition by Dr. E. G. Brackett and Dr. F. J. Cotton. In one case a man, aged 30 years, gave a history of good health until four years previously, when he began to suffer from occasional pains in the hips, thighs, and knees. Then swelling of the knees occurred periodically for a few days. The trouble gradually increased with greater disability not only at the time of the swelling but in the intervals. Change of residence to various parts of the United States proved useless. When he was seen his general condition was below normal. The knees became swollen alternately with perfect regularity. There were first feelings of heat and pain and tenderness of the joint with malaise. In two or three days the joint became filled with fluid. The swelling gradually disappeared in about four days. One knee was fixed and quinine was given in daily doses of 20 grains. The intervals between the attacks were lengthened by one or two days, then an attack was omitted, then the attacks became slighter and less frequent, and finally they disappeared. In the intervals the only symptoms were weakness of the knees and some limitation of flexion and extension. In the second case the patient was a woman, aged 35 years, in good general condition. The first attack followed slight injury of the knee. The joint became swollen every 10 days for a period

of four days. In the intervals there was no disability. The treatment followed in the first case was unavailing, but the condition gradually yielded in the manner of the first case to persistent treatment by arsenic, strychnia, and creasote. Fixation and local treatment were useless. In nearly all of the recorded cases, which amount to 68, a calendar-like regularity of the attacks is described. The joint most frequently affected is the knee. In 41 out of 55 cases one or both knees were involved without affection of other joints. The hip, shoulder, elbow, wrist, ankle, jaw, and spine have been affected. One joint alone may be affected for many years, or after a time others may be affected simultaneously or alternately. As a rule local heat and redness are absent and tenderness is often absent. In many cases there was no pain, only discomfort; in others pain was marked. In a case recently described by Benda there were for years periodic pains in various joints at monthly intervals before effusion appeared. Much pain may occur in the earlier attacks and less in the later. Languor during and after the attacks is common. Headache, chilliness, or slight pyrexia is described in a few cases. The duration of the attacks varies greatly. The extremes are a case of daily attacks lasting an hour and a case of attacks lasting from 19 to 21 days with intervals of eight days. The duration most often recorded was three or four days. The time of recurrence was singularly constant. From beginning to beginning of attack the most usual period was 14 days, the minimum was 24 hours, and the maximum was three months. A change of interval is described in some cases—e.g., from 30 days to eight days, from three months to 11 days, from seven days to three days, and from 14 days to 21 days. In some cases this change followed temporary immunity. In a few cases there was progressive shortening or lengthening of the interval. In some cases the periods corresponded to those of menstruation. The average age at the onset was 26 years; the extremes were 12 years and 54 years. As to sex there was a slight preponderance of females. The weak and the robust were apparently equally affected. Intermissions sometimes occurred and lasted for several years. In five cases the attacks stopped during pregnancy, but such intermission was not constant, even in the same patient. In the majority of cases there were no articular signs in the intervals except sometimes a little thickening or laxity of the capsule, or crepitation. Of the pathology nothing is known and therefore a number of theories exist. The one most accepted is that the disease is a vaso-motor neurosis. In favour of this are the concurrence of angio-neurotic oedema in some cases and of functional nervous disorders in others, and the influence of mental conditions on the attacks. The remedies recommended, as might be expected, are numerous. Arsenic and quinine seem to be the best remedies, but the prognosis is not good.

#### THE METROPOLITAN WATER-SUPPLY.

It is announced that during the next session two Bills will be promoted in Parliament, each of which contains clauses having reference to the purchase of the metropolitan water companies. Of these Bills one is apparently to be adopted as a Government measure, the other is promoted by the London County Council. We do not propose on the present occasion to consider in detail the provisions of the Government Bill, but it may be of interest to mention some of the points with which it deals. The great central feature of the Bill is the formation of a new public authority—a Water Board—which is to be invested with power to purchase the existing metropolitan water companies and the property now vested in the Staines Reservoirs Joint Committee and after a certain date to undertake the responsibilities and duties of supplying the water within a certain defined area. It may be remarked that the drafting of the Bill in regard to

this last matter shows that care has been bestowed on matters of detail. The area which it is proposed should be under the control of the Water Board includes Sunbury, Chessington, and Cuddington, places which are at present supplied without parliamentary authorisation. The suggested method of appointment of the members of the Water Board will naturally excite interest. They are to represent the councils of certain counties, boroughs, and urban districts, the Corporation of the City of London, the Thames and the Lee Conservators, "and any other bodies or persons that may be named in the intended Act." Full provision is made as to the method of purchase of the present water undertakings, and the Board are to be enabled to inspect the lands and to examine the accounts of the companies. A "water stock" is to be created to enable the Board to acquire the property of the water companies, and it seems likely that some advice given to the Llandaff Commission by Mr. Banbury on this point has not been entirely disregarded. A brief study of the chief provisions of the Bill shows that a considerable amount of thought and trouble has been bestowed on it and that it is at least worth very careful consideration. The London County Council Bill provides for the purchase of the Metropolitan Water Companies and the Staines Reservoirs Joint Committee's undertakings by that body. It contains provisions as to the manner in which the purchase is to be made and how the money required is to be raised. Provision is, moreover, made as to the re-sale of part of the undertakings to county or local authorities whose districts are outside the county of London.

#### OBJECTIONABLE ADVERTISEMENTS.

ADVERTISEMENTS of the class with which we dealt in our articles entitled "Quacks and Abortion" are beginning to re-appear, after having been for a time less conspicuous than formerly. It was hardly likely that the prosecution of the Chrimes brothers and of "Madame Frain" would cause others permanently to abandon a profitable trade, and it is a trade which lives by advertisement and can afford to pay for it. We have before us the November number of *Leach's Family Dressmaker* and the December, or Christmas, number of *Leach's Children's and Young Ladies' Dressmaker*, two papers emanating from the same office, which appear, as their names imply, to afford hints and instructions on needlework and the making of clothes to the female members of middle-class or lower middle-class households. In both of these we find advertisements of Allen (the Irristum Company)<sup>1</sup> and of Martin's apiol and steel pills for ladies, whose wares and literature we have dealt with fully in THE LANCET.<sup>2</sup> In the *Family Dressmaker* we find the advertisement of "'Dr.' Davis's Famous Pills, a Boon to Womankind," of which also we have written.<sup>3</sup> In both papers are several other advertisements either promising cures for "obstructions" or otherwise inviting women to try quack medicines the object of which is thinly disguised or left to the intelligence of the reader to supply. The chief difference between the two papers is that the *Family Dressmaker* appears to group all its advertisements of this class on one page, the inner page of its cover, while the other paper scatters them. We cannot say that either method of making such trades known is worse than the other, but we call attention to the fact that Allen's advertisement and that of "M.D.," to which we shall refer below, appear facing an article in the *Children's and Young Ladies' Dressmaker* entitled, "How to Make your own Christmas Cards," which begins: "I fancy every girl at some epoch in her career cherishes a secret ambition to design her own Christmas cards"—an article clearly addressed to young girls

and not to their mothers. Facing this article there also appears this advertisement:—

**TO THE MARRIED.—EVERY Married Couple** should write at once for my INVALUABLE BOOK of ADVICE, which contains everything that a wife ought to know. It is sent GRATIS on receipt of address.—Apply, Dr MAURIER, 110, Clarence Road, Clapton, London.

The advertisement of "M.D.," referred to above, is as follows:—

**TO MARRIED LADIES.—MY Remedy** is not a dangerous drug, but a wonderful Secret Invention. Never fails. No quackery. Particulars Free to all Applicants on receipt of a stamped addressed envelope.—Apply to M.D., 217, Graham Road, London, N.E. Caution.—Only Address.

As it was one that we did not remember to have observed before we caused a letter to be written as from an unmarried woman asking for the particulars promised, and received in reply the price-list of "Malthusian appliances" which so frequently and so clearly indicates the object of the "remedy" offered, together with a leaflet describing the "remedy" itself, which in this case is entitled "Paris Pills." These are stated to contain secret "powerful ingredients protected by Government stamp," with regard to which untrue statement we may point out how undesirable it is that the taxing of nostrums should so be done as to enable Government "protection" to be falsely claimed for them. On the same leaflet appears conspicuously the sentence, "Not to be taken in cases of pregnancy or for an unlawful purpose," which is the warning so often found in the literature connected with these "remedies," a warning which in this case again draws attention to the powers claimed for the "Paris Pills" by the advertiser. From Allen we have received in reply to a similar application full particulars of the merits of "Irristum," with testimonials, which, as far as we see, are the same as, or similar to, those which we have had before from the same address. With regard to all these advertisements and to many others like them, which, no doubt, the proprietor of Leach's journals may from time to time be offered if he shows himself willing to admit them to his columns, we have nothing to add to what we have already written on this subject. They offer drugs in terms which are calculated to induce pregnant women to buy them in the hopes that they may be able to produce abortion upon themselves. They are either incentives to actual crime or, if mere swindles, they cause ignorant persons to attempt crimes which the drugs themselves are, perhaps, not calculated to enable them to commit. In any case their nature cannot be said to be concealed by the terms employed, and it is only surprising that respectable firms should allow their own advertisements of the goods in which they lawfully trade to appear in the same paper and on the same page with such notices as those which we have quoted and commented upon. We note, for example, the advertisement of Messrs. Allen and Hanbury on the page of the *Children's and Young Ladies' Dressmaker* to which we have drawn special attention.

#### THE OPEN-AIR TREATMENT OF PHTHISIS AND THE CONDITION OF THE TEETH.

In a recent address to the Odonto-Chirurgical Society Mr. H. B. Ezard drew attention to the very unsatisfactory condition of the teeth of many of the patients undergoing the open-air treatment for pulmonary tuberculosis. In this treatment, as is well known, the feeding of the patient is most important, and to obtain the greatest amount of value from the food it is necessary that the act of mastication should be efficiently carried out. Professional curiosity seems to have led Mr. Ezard to examine the teeth of the patients in a sanatorium in which he himself was undergoing treatment. The result of his investigation was as follows: "Out of 192 possible molars 12 were in action.

<sup>1</sup> THE LANCET, Dec. 24th, 1898, p. 1723.

<sup>2</sup> THE LANCET, Dec. 31st, 1898, p. 1808.

<sup>3</sup> THE LANCET, Dec. 31st, 1898, p. 1808.

and taking the average age, 26, out of the possible 32 teeth only eight were in action—i.e., 75 per cent. of the first process of nutrition had been lost." These figures speak for themselves and indicate that the importance of the teeth has been in some cases unconsciously overlooked by medical practitioners in whose care such patients are placed. There is, however, another point in connexion with the mouth to which Mr. Ezard did not draw attention—namely, the importance of rendering all mouths as far as possible aseptic by the removal of septic teeth and the treatment of suppurative conditions of the gums and peri-odontal membrane. Recent writers have shown that the constant absorption of septic matter generated in the mouth is a fruitful cause of systemic disease, more especially of the alimentary tract. Such septic matter if present in the mouth of those undergoing the open-air treatment must to a great extent counteract the advantages gained by the remedies employed. In combating tubercle no stone should be left unturned in endeavouring to restore perfect nutrition, and the condition of the mouth certainly should claim the attention of those having the care of such patients.

#### PROFESSOR W. J. R. SIMPSON.

PROFESSOR SIMPSON, while engaged upon the inquiry into the prevalence among our army in South Africa of dysentery and typhoid fever, was, it may be remembered, requisitioned at Cape Town upon the outbreak of plague there. At Lord Milner's request the Government offered to place his services at the disposal of the Government of Cape Colony, and during some months of his stay in South Africa he superintended the measures taken for the prevention of plague in that colony. This week he has started to investigate the causes of the prevalence of plague in Hong-Kong. Professor Simpson is utilising in a splendid manner in behalf of his country the unique experience of epidemic disease in tropical and eastern climates which he gained during his long tenure of office as medical officer of Calcutta. Many will envy him the credit of his responsible appointments, but few appreciate the strain that such work, thoroughly conducted, puts upon the investigator.

#### THE FEES OF IRISH MEDICAL WITNESSES.

AN appeal recently heard in the Dublin courts shows that in the matter of fees allowed to witnesses the law governing costs in Ireland might well be assimilated to that of England. The particular facts of the case in question are alluded to by our Dublin Correspondent. It will suffice to say that an action had been won involving judgment for damages and costs by a man who had been injured by the defendant's negligence. Certain attendances of medical witnesses had been allowed by the taxing-master at five guineas a day, but the King's Bench Division on appeal held that the taxing-master had no discretion to go beyond the scale laid down for his guidance and that the allowances in question must accordingly be reduced to a guinea each, one of the judges expressly calling attention to the fact that in England the taxing-master has a discretionary power in these matters, while in Ireland the rule is binding. He might have added that in certain circumstances even in a county court action in England by the order of the judge the fee allowed to a scientific witness may exceed the guinea prescribed by the Irish rule. We need hardly point out that any hard-and-fast rule cutting down the fee of the medical practitioner to beggarly proportions operates to the prejudice of the poor man in all those cases in which he is the plaintiff and in which, as is usually the case, the defendant is better endowed than he with the means with which to carry on litigation. The medical man cannot sacrifice his usual earnings from his profession, possibly for several

days, without compensation, and the person who has been injured is obliged to call a witness whom he can only hope to repay out of the damages which the jury may award him. It must not be forgotten that the medical man may find himself, owing to circumstances beyond his control, almost bound in honour to assist with his testimony a patient whom chance threw in his way and whom, when he came to him as a patient, he could not have refused to attend. He is a member of a profession which in this respect is unique, and the hardship imposed upon medical practitioners and patients by the rule referred to may well occupy the attention of those who have framed and can presumably amend the Irish rules relating to law costs. Where, as in England, the fees are more or less a matter of discretion they do not even then in most cases compensate the witness for the pecuniary loss which lost time implies, while of trouble and anxiety they take no account.

#### PREGNANCY AND NORMAL LABOUR AFTER EXTIRPATION OF ONE KIDNEY.

IN the *Deutsche Medicinische Wochenschrift* of Nov. 21st Dr. Steinheil of Kochendorf-Jagstfeld relates the following case. In June, 1895, he was consulted by a woman, 25 years of age, and not long married. She was of stout build and felt well but was very pale. Her left kidney had been removed for tuberculous disease seven years previously by Professor König who had warned her that pregnancy would be dangerous for her, and every endeavour had been made to avoid conception, but she was nevertheless now in about the second month of pregnancy. In the region of the left kidney there was a firm painless operation scar. Slight pains, not precisely localised, were felt in the abdomen. The urine, which was passed in small quantity, often with a certain amount of effort and sometimes involuntarily, contained much pus and a little blood. Dr. Steinheil already knew of cases in which pregnancy and normal labour had occurred after extirpation of the kidney, and he thought that in the present instance there would be less risk in waiting than in inducing premature labour. The woman felt quite well all through the pregnancy. Labour occurred in February, 1896, and was completed with forceps. Retention of urine, however, followed and was attended by such extreme pain, if not promptly relieved, that it was deemed necessary to use a self-retaining catheter, but the mucous membrane of the bladder showed itself more tolerant of catheterism than might have been expected; normal micturition was re-established on Feb. 25th and by the end of March the patient was able to travel to a different part of the country. After this she enjoyed good health for more than a year and a half, dying in November, 1897, but from what disease Dr. Steinheil did not know. The child remains in good health.

#### THE NATIONAL DENTAL HOSPITAL AND COLLEGE.

THERE was a very successful gathering of the past and present students of the National Dental Hospital and College on Nov. 29th at the Royal Venetian Chamber of the Holborn Restaurant, when the annual dinner was held. Mr. S. J. Hutchinson, who presided, in proposing the toast of "The King," testified to the interest which His Majesty always took in medical charities, and referred in congratulatory terms to the fact that the King had recently given permission to the sister dental institution to prefix the word "Royal" to the title of the hospital. This toast having been drunk with musical honours, that of "Her Majesty the Queen and the rest of the Royal Family" was also received with enthusiasm. In proposing the toast of the evening, "The National Dental Hospital and College," the Chairman dwelt on the enormous responsibilities which

devolved upon the dental hospitals and the dental departments of general hospitals with regard to the health of the community, remarking that the future strength of the empire would very largely depend upon the care of the teeth. As an example of the importance of the care of the teeth he stated that no less than 50 per cent. of the applicants for employment in the South African Constabulary were rejected because they had not a sufficiently practical masticatory apparatus. The War Office, he was glad to say, had already recognised the importance of dentistry and before many years had elapsed, he believed, there would be a properly organised dental department in the army. The chairman concluded by referring to the excellent opportunities for study which presented themselves at the National Dental Hospital. Mr. P. Sidney Spokes, the Dean, in responding, said that the school was in a flourishing financial condition. The aim of the college in teaching was to give the student self-reliance and to impress upon him the fact that the tooth was only one organ in a very complex organism. He mentioned that for the benefit of old students it was proposed early in the new year to offer them a course of bacteriology in order to put them in line with the present teaching. Mr. Spokes then presented a handsome "tantalus case" to Mr. Marcus Davis who is resigning from the staff. Mr. Davis briefly replied. The other toasts were "The Past and Present Students," proposed by Dr. H. P. Noble and responded to by Mr. P. G. Pavitt and Mr. J. P. Glassington; "The Visitors," proposed by Mr. Glassington and responded to by Major Woods; and "The Chairman," proposed by Mr. W. Rushton. The proceedings of the evening were enlivened by a programme of music, songs, and recitations.

#### THE PHYSIOLOGY OF THE HYPOPHYSIS CEREBRI.

IN an article on this subject in Pflüger's *Archiv für Physiologie*<sup>1</sup> E. von Cyon observes that this body has awakened great interest and has been the subject of many experiments which, however, are not always in accordance with each other. The method of ablation can hardly be practised on account of the anatomical position of the hypophysis, but the organ is accessible from below, where it can be exposed by the use of a trephine without much difficulty. The results of his investigations are as follows. The hypophysis cerebri has a double function: it regulates the intracranial blood-pressure and it regulates metabolism. The former function is effected mechanically by the circumstance that every increase of blood-pressure in the brain constitutes a stimulus to the hypophysis and is followed by an increase in the strength and a slowing of the cardiac beats with slight rise of the extracranial pressure. These rarer and stronger beats of the heart, which von Cyon names "action-pulse," augment the rapidity of the venous blood current, especially in the veins of the thyroid body, and thus remove from the brain the abnormal quantity of blood. There is reason to believe the same effect is in part due chemically to the production of substances which are probably two in number, one of which persistently excites the vagal centres whilst the second excites the accelerators. The action-beats caused by these coincident and harmoniously acting antagonistic agents are highly favourable to the rapidity of the venous blood current. The influence exerted by the hypophysis and its secretions on metabolism is also probably effected by their action on the vagi and sympathetic nerves, and is indicated by increased oxidation and a diminution of body-weight. Persistent stimulation of the hypophysis, especially by electrical currents, is followed, as a secondary effect, by violent epileptiform convulsions, which are most easily explained by regarding them as disturbances

of the circulation in certain parts of the brain. Von Cyon noticed, but was of opinion that the circumstance was worthy of further corroboration, that erection of the penis took place which remained long after the hypophysis had ceased to be excited. Another phenomenon was observed in all cases of electrical stimulation of the hypophysis—a great increase in the secretion of urine.

#### MODERN VACCINATION.

THE debate at the meeting of the Royal Medical and Chirurgical Society to be held on Dec. 10th promises to be of extreme interest. It will follow an address to be given by Dr. Monckton Copeman upon "Modern Methods of Vaccination and their Scientific Basis." The address will be copiously illustrated by lantern slides, and the subject is specially interesting at the present time when, as a reference to our columns will show, small-pox is by no means upon the decrease in London.

#### DINNER OF THE OTOLOGICAL SOCIETY.

THE second annual dinner of the Otological Society of the United Kingdom was held at the Café Monico on Dec. 2nd. About 70 members and guests were present, the chair being taken by the President, Sir William Dalby. Among the guests were Sir Thomas Barlow, Sir James Crichton Browne, Dr. Ferrier (the President of the Pathological Society), Mr. Watson Cheyne (the President of the Medical Society of London), Dr. W. H. Allchin, and Mr. Bernard Pitts. After the toast of "The King" had been honoured Sir James Crichton Browne proposed "The Otological Society." He pointed out that the need for further specialisation than had formerly existed was owing to the vast extent of modern medical knowledge, so that a divorce, or at least a judicial separation, between the ear and the throat had become a necessity. The President, in reply, stated that the large amount of the work which the society had accomplished during the past year was sufficient justification for its existence. Mr. Stephen Paget in a felicitous speech proposed the toast of "The Guests," and Sir Thomas Barlow, in acknowledging it, asked that the special researches and results dealt with by the society should not be confined to it, but when matured they should be brought to the older medical societies, so that the whole profession might appreciate and participate in these advances in knowledge. Mr. Charles A. Ballance proposed the health of the retiring president, and Dr. Urban Pritchard also said a few words. The toast was received with enthusiasm. An interesting novelty was the toast-list; it was ornamented by instruments employed in aural surgery and by parts of the ear, such as the ossicles and the labyrinth.

#### PHOTOTHERAPY WITH THE FOVEAU-TROUVÉ APPARATUS.

THE value of Finsen's method of phototherapy in skin diseases, particularly in lupus, is now well attested. But the apparatus is costly and the treatment is very tedious. In the *Progrès Médical* of Nov. 2nd Dr. Foveau has described a simpler and much less costly apparatus which, in conjunction with an electrician, M. Trouvé, he has recently invented, and which is used in the St. Louis Hospital, Paris. It apparently gives as good results as Finsen's apparatus, and has the important advantages of greatly diminishing the duration of each sitting and increasing the extent of surface which can be treated. Moreover, it can be fixed anywhere—e.g., in the house of the medical man or in that of the patient. It consists of a parabolic mirror with an incandescent or arc lamp in the focus. The former is joined to a "concentrating cone" which terminates in two quartz plates with a chamber between

<sup>1</sup> Band lxxviii., 1901, p. 565.

them. In this chamber and through the whole apparatus cold water circulates which, as in Finsen's apparatus, absorbs the heat rays. But instead of using a special instrument for compressing the skin to render it exsanguine, the quartz plate, which is of variable size and surface, is pressed directly on the part to be treated. Comparing the Finsen with the Foveau-Trouvé apparatus Dr. Foveau claims the following advantages: cost of installation of the former 4000 francs, of the latter from 200 to 300 francs; expense of each sitting with the former 15 francs, with the latter 0.23 franc; duration of sittings with the former 75 minutes, with the latter 10 minutes; surface treated with the former one square centimetre, with the latter from one to five square centimetres, as required.

#### SMALL-POX IN LONDON.

As was expected with the advent of cold weather, the cases of small-pox show no decrease. On Saturday, Nov. 30th, there were 30 fresh cases notified and removed. On Sunday, Dec. 1st, the number was 16; on Monday, the 2nd, there were 31 fresh cases; on Tuesday, the 3rd, there were 28 fresh cases; and on Wednesday, the 4th, there were 33 fresh cases.

THE report of the Commission appointed by the Government in August, 1900, to inquire into "the nature, causation, pathology, and modes of prevention (more particularly as affecting armies in the field) of dysentery and its connexion, if any, with enteric fever," has been handed in to the Secretary of State for War and we may expect shortly to be able to comment upon it. Colonel Bruce, R.A.M.C., is responsible for the laboratory part of the investigation, while the subdivisions of the report dealing with the sanitary and preventive measures to be taken are from the pen of Professor W. J. R. Simpson, who, with Colonel Lane Nottter, R.A.M.C., made up the Commission.

THE Fellows and Associates of the Institute of Chemistry assembled under Professor J. Millar-Thomson, F.R.S., the President, for their annual dinner on Wednesday, Dec. 4th. The President was supported by a distinguished company. The Minister of Agriculture, in an able speech, emphasised the importance of scientific chemistry to agriculture. The President gave a general report on the condition of the institute, pointing to the advance that that body was steadily making in the high standard of its examinations.

THE governors of the Macclesfield Infirmary have invited the honorary consultant physicians and surgeons of the institution to a private conference upon the situation caused by the election of a female junior house surgeon in opposition to the wishes of the medical staff. The medical staff expect, and so do we, that their professional colleagues will find that they have taken the right course in sending in their resignations to a governing body which disregarded their views in a pointed manner upon professional subjects.

SURGEON-GENERAL W. TAYLOR, C.B., having arrived in this country from India presumably in order to fill the appointment of Director-General of the Army Medical Service, may be expected to take up the work of his post at once. We heartily congratulate Surgeon-General Taylor on his promotion and tender him our best wishes in the successful discharge of the new duties he is undertaking.

WE received with much surprise and regret the news from India of the death of Surgeon-General Robert Harvey, C.B., D.S.O., Director-General of the Indian Medical Service. Surgeon-General Harvey had only left England three weeks

or so before his death, which must have occurred immediately upon his arrival in India. We shall publish an account of his career next week.

THE secretary of the Sanitary Institute gives notice that it has been decided not to hold the sessional meeting on Dec. 11th as given in the calendar in the supplement to the journal of the institute.

MR. THOMAS BRYANT will open the new out-patient department of the Bolingbroke Hospital on Wednesday next, Dec. 11th, at 3 P.M.

DR. WALTER ESSEX WYNTER has been elected physician to the Middlesex Hospital.

## Pharmacological Notes.

#### LACHNANTHES.

THIS American plant, known colloquially as red-root or spirit-weed, is derived botanically from *Lachnanthes tinctoria*, Elliott; but so far does not appear to be well known to British pharmacologists. We are therefore dependent for our information upon American sources. According to King's "Dispensatory," recently published, the plant is a native of the United States. Its reputation was built upon the perennial root which was first introduced into practice by the homoeopathic school. It had long been used, according to Dr. Byron, by the Florida Indians for its stimulant properties; thus they are said to have resorted to its use for the production of brilliancy of eye, flushed face, bold appearance, and eloquence of speech. After these effects have passed away the patient is said to become stupid and irritable. The chemistry of this drug does not seem to have been worked out. The position of the plant in the natural system of classification of Bentham and Hooker is under the monocotyledones, near the natural order Iridaceæ. It belongs to the family Hamendoraceæ, and is therefore far removed from belladonna, which it is said to resemble in physiological action. The pharmacy of *lachnanthes* is quite simple. A 1 in 10 proof-spirit tincture of the plant is prescribed in from 2-minim to 10-minim doses. Thus one fluid drachm of the tincture in four fluid ounces of water forms a mixture of which one teaspoonful may be given every three or four hours. With regard to its therapeutic and physiological effects the drug has been recommended for checking the cough of consumptive patients, for the treatment of pneumonia, in nervous fever and typhus fever, for some diseases of the brain, in the delirium of fever, and in morbid conditions of the brain and nervous system, especially when in these several maladies redness of the cheeks and brilliancy of the eyes are accompanying symptoms. It is said to be efficient in cases of wry-neck, hoarseness, laryngeal cough, tinnitus aurium, and nervous headache. Large doses produce dilatation of the pupils, impaired vision, dizziness, and other unpleasant symptoms somewhat similar to those produced by belladonna. Its action, however, would appear to be uncertain, and with regard to pulmonary affections it is probably an expectorant, with less power than *ipecacuanha*.

#### VIOLET LEAVES.

The leaves of the well-known violet plant are being vaunted as a local application for cancer in the form of an infusion of the fresh leaves. The plant is by no means new to medicine, having been employed as a domestic remedy in ancient Rome. In the United States of America, where it has probably received more attention than in this country, the whole plant is taken or else a part, e.g., the green herb, the root, the seeds, the leaves, or the flowers deprived of their calyx. As to the botanical origin, either *Viola odorata*, Linné, the sweet violet, or any other species, may be given for medicinal use. As to its chemistry, the whole plant of *Viola odorata* contains an acrid poisonous principle which was named "violine" by its discoverer, Boullay, in 1828. This substance resembles emetine in its action, is a white or pale yellow powder of an acrid taste, more soluble in water than is emetine, and soluble in alcohol, but insoluble in ether and forming insoluble compounds with tannins. This principle is found in other species of *viola*, especially in the

stemless variety, but not in the pansy (*Viola tricolor*). The root contains starch, a yellow colouring matter, gum, and traces of volatile oil. The flowers contain a blue colouring matter which is turned green by alkalis. The odoriferous principle has not been definitely established, nor is it known whether it is identical with the synthetical violet perfume or with that obtained from orris-root. The violet odour of orris-root was shown by Tiemann and Krüger (1893) to be due to a ketone (irone) and it is probable that the same substance causes the natural odour of the violet. Irone, and an allied substance, ionone, are both injurious in their effects on the animal organism when taken internally, as shown by Professor F. von Mering's experiments upon himself and upon dogs. In view of a recent discussion as to the harmful effects of violet perfume on the voice these notes are of interest. K. Mandelin found that the leaves of the violet contained a substance which yielded salicylic acid after boiling.<sup>1</sup> He found a little of the free acid in the rhizome. With regard to pharmacy, the herb and the root are said to yield their active principles to water. There is an idea prevalent that the plant should be used in the fresh state as drying destroys the active principles. The taste of the flowers is sweet and mucilaginous; that of the rhizome is bitter, mucilaginous, and subacid. The flowers of *Viola odorata* are used in the French Codex in preparing a syrup thus: fresh deep-blue flowers, minus calyx, are infused with twice their weight of boiling water, and then to every 21 parts of infusion are added 38 parts of sugar to form a syrup. If the whole plant is employed for medicinal purposes it should be gathered as soon as the flowers have being expanded, each flower being deprived of its calyx and, according to King's "Dispensatory," from which we have derived much of our information, dried. As to the dose, of the flowers and seeds, as a laxative, from three to four drachms rubbed with sugar and water, presumably into a confection, and of the root from one-half to one drachm as an emeto-cathartic. This is uncertain in its action. The root is administered in from 8-grain to 10-grain doses as a tonic and in from 25-grain to 30-grain doses as a purgative, while from 40 to 60 grains constitute an emetic dose. The root, leaves, and seeds are emetic in the larger doses. P. L. Simmonds states that the whole plant of *Viola odorata* is largely sold in the bazaars in Bengal for making an infusion as a diaphoretic in fevers and that large doses nauseate and produce vomiting. It is not known whether the odorous emanations from the flowers are poisonous, but they have been known to produce giddiness and faintness. The seeds have been recommended in uric acid gravel, and, in conjunction with *Corydalis formosa*, in the treatment of syphilis; also in pectoral, nephritic, and cutaneous affections, especially in *crusta lactea*. Professor Scudder states that the plant stimulates waste and secretion, relieves nervous irritation, and improves nutrition. Further information about this drug is wanted.

#### POISONING BY BELLADONNA PLASTER.

Dr. W. Makeig Jones<sup>2</sup> has drawn attention to a case of poisoning by belladonna plaster which requires explanation. The patient had removed the first plaster from the costal region and applied a second; after 12 hours severe symptoms of belladonna poisoning were experienced. The skin beneath the plaster was found to be swollen and covered with a rash. Though the patient speedily recovered under treatment the toxic effects remained for some days. The fact that the symptoms did not appear until the application of the second plaster eliminates the factor of idiosyncrasy. The suggestion of Dr. Jones that the plaster may have been fortified by the addition of alkaloid after manufacture is based on the fact that the original strength of the plaster should be 0.5 per cent. of alkaloid, whereas the second plaster was found, on removal, to contain 0.44 per cent., the loss representing a quantity too small to produce the effects observed. This suggestion leads to the natural inquiry, what is the amount of alkaloid that would normally be absorbed through the skin in a given time? Until this question receives a satisfactory answer it is scarcely fair to lay the blame on the plaster, nor is this one case sufficient to bring the belladonna plaster into disrepute.

#### THE VALUE OF ETHER IN OINTMENTS.

H. Wyatt<sup>3</sup> has called attention to the use of ether in ointments—a practice recommended by Sir James Sawyer in

cases where absorption is required in applications to the skin. The ether, in the proportion, say, of two fluid drachms to six drachms of ointment, softens or dissolves the sebaceous secretions in the skin, thereby enabling the latter to take up the medicament.

## THE LONDON LICENTIATES AND MEMBERS SOCIETY.

A MEETING of the London Licentiates and Members Society was held at the Wimpole Hotel, London, on Nov. 29th, Dr. FREDERICK J. SMITH being in the chair.

Dr. SMITH said that there were three schemes arising out of the minutes of the preliminary meeting of the society which were on the agenda for the present meeting. The first was to petition the Royal College of Physicians of London to rescind By-law 177, which by-law was to the effect that the Royal College did not grant to its Licentiates any power to call themselves "Doctor." The second was to petition the Royal Colleges of Physicians of London and Surgeons of England to obtain power to grant the degree of M.D. and the third was to petition the two Royal Colleges to approach the London University and prevail upon that body to admit Licentiates and Members of the Colleges to the final examination for the M.D. of that university. The last suggestion seemed to him to fulfil every reasonable expectation of the Licentiates, and to promise to put the Licentiates at once into a position from which no one could possibly disturb them. There was a statute of the University which distinctly gave power to the new university to "associate" itself with the existing Colleges in London, so as to promote in any way that they might think right the advancement of medical education, including examination. He thought that Licentiates should be admitted to the final examination of the new university by arrangement with that university.

Mr. F. W. COLLINGWOOD favoured the third suggestion and referred to the grave disabilities which the double-qualification men of London laboured under. It was stated in THE LANCET of Nov. 23rd that it was the universal opinion of the leading London physicians and surgeons in 1886 that the students in London were under grave disabilities, and that when the Colleges by a unanimous vote asked that they should grant degrees it was met by the Crown with a distinct negative, and he thought the decision must have been made under some misconception of the facts.

Mr. DOUGLAS did not agree that there should be any further examination for the title "Doctor."

Dr. SMITH said it would not be practicable for any corporate body to give the M.D.

Mr. E. R. DAWSON maintained that the double-qualification men passed a better examination than that for the M.B. of Cambridge.

Dr. W. G. DICKINSON pointed out that London corporations, including the London University, were fee-getting institutions, and no degree would be obtained without paying more money.

Mr. A. E. JOSCELYNE said that he thought it would be very much better to have an examination.

Mr. ARTHUR GREENWOOD supported the third proposition.

Dr. SMITH alluded to the fact that the London medical schools were now fighting for their existence—a fact which the authorities and the teaching staffs recognised. The proposals would not be less likely to succeed on that account, for it would be felt that the existence of the London schools was at stake. Provincial students had increased by 800 while those in London schools had decreased.

Mr. P. ROSE hoped that the standard of the London M.D. would not be lowered.

Dr. SMITH said that the examinations of the new University of London were still in the crucible, and he hoped that the representations which would be made might have influence in determining the standards.

Mr. COLLINGWOOD said that the new university should lay itself out for a more liberal distribution of degrees, seeing that it was the only university for a population of over 5,000,000 people.

Dr. SMITH suggested that the proposed petition might mention a thesis as a qualification for a degree.

<sup>1</sup> American Journal of Pharmacy, 1882, p. 11.

<sup>2</sup> Quarterly Medical Journal, vol. ix., p. 29.

<sup>3</sup> Pharmaceutical Journal, 1900, vol. i., p. 129.

Mr. JOSCELYNE proposed, and Mr. F. C. LANGFORD seconded, the following motion:—

That a petition be sent to the College of Physicians and College of Surgeons requesting them to approach the London University and prevail upon that body to admit Licentiates and Members of the Colleges to the final examination for the M.D. degree of that university.

This was carried unanimously.

A committee composed as follows, with power to add to the number, was appointed to frame the petition and forward the interests of the society:—Dr. F. J. Smith, Mr. A. E. Joscelyne, Mr. P. Rose, Mr. E. R. Dawson, Mr. F. C. Langford, Mr. F. W. Collingwood, Mr. W. E. Morgan, and Mr. E. H. Tipper.

Dr. SMITH was then unanimously elected President of the society, and in acknowledging the compliment he said that he was ready to do all in his power to further the movement.

## Looking Back.

FROM

THE LANCET, SUNDAY, DEC. 7, 1823.

*Various Games adapted for the Members of the Medical Profession.*

*To the Editor of The Lancet.*

MR. EDITOR,—I admire the discretion which has induced you to introduce into your well conducted publication, lessons in chess for the purpose of insinuating under the guise of that game the maxims of the therapeutic art—

—“ut pueris olim dant crustula blandi  
Doctores elementa velint ut discere prima.”

It is well known that Podalirius and Machaon played at chess at the siege of Troy with Palamedes the inventor of it. I have to suggest, however, that you should not confine yourself to chess alone, especially as it is a game of skill merely, but should extend your amusing and useful labours to other games, which bear a stricter analogy to the *Ars Medica*.

I need hardly mention *Draughts* for their extensive utility, they are certainly among the *prima elementa* of the general practitioner.

*Push-pin* manifestly tends to increase the *tactus cruditus*.

*Dominoes* inculcate the necessity of the juxta-position of similar parts, and give warning of the evil consequences of a solution of continuity. They form an evidently sanative game.

*Nine-pins* and *bowls*, from their very forms, like two ounce phials and pills, are evidently intended to do honour to medicine.

The various games of *cards*, however, seem particularly designed for the use of medical practitioners, and may be called the microcosm of medicine. In *Whist* there is the necessity of *cutting*, which involves much surgical knowledge; and *shuffling*, which is useful in all branches of the profession. The good player will rely more on *tricks* than on *honours*. The propriety of never omitting to call, is inculcated on the physician, while the maxim of returning your partner's lead, adumbrates that good understanding between *Doctor* and *Apothecary*, which may be termed the *Holy Alliance of London practice*. Some practitioners have played well at *matrimony*. *Pope Joan* conveys a curious historical fact, and may thus increase the general knowledge of the student.

There is a game mentioned by Dr. Rabelais, under the name of *Flux*, which I am ignorant of; but I doubt not, if it were investigated by your learned collaborators, it would throw light on the nature of cathartics. The same astute physician mentions the game of *Pille*; but the word, with him, (in French) is not taken in the sense of *pilula*, but is the imperative of *piller*, to *rob*, *strip*, or *pillage*. In English, it might be called *bill*, and refers to the mode of making a *charge*.

*Blind Hookey*, the *cœca rapacitas* of the Latins, is a game venerable for its antiquity, and truly medical.

*Put the fool to bed*, is a game little used; but it conveys

an useful instruction as to the mode of dealing with a patient. *Ned quid plura de hoc joco adlam!*

*Kalendis Decembris.*

H. U. M. D.

## ASYLUM REPORTS.

*Suffolk County Asylum (Annual Report for 1900).* The average number of patients resident during the year was 591 and comprised 252 males and 339 females. During the year 178 patients were admitted, and of these 140 viz., 75 males and 65 females—were first admissions. Dr. James R. Whitwell, the medical superintendent, states in his report that as regards the numbers resident in the asylum the figures tend to show “an increase on the female side which will necessitate early boarding-out unless some other form of relief to overcrowding occur shortly.” The bodily condition of patients on admission was not as a rule satisfactory. A considerable number of patients were brought to the asylum in an “enfeebled and exhausted condition as a result of attempted treatment at home which generally results in the patient being so physically reduced as to be unable to stand the severe strain of an acute mental disease.” Dr. Whitwell adds that there is every reason to believe that many of these patients, now apt to die or to lapse into chronic and incurable insanity, would have recovered if brought earlier under treatment. Hereditary tendency to insanity was ascertainable in 36 per cent. of the patients admitted, and there was every reason to believe that this figure was much smaller than the actual facts would show if these could be ascertained. It was difficult to obtain exact information of the rôle of alcohol as a factor, though this could be traced in 14 per cent. of the cases. Moral and emotional conditions when analysed carefully appeared to form no very important element in the production of insanity except as an exciting factor. The death-rate for the year has been rather higher than usual, the total number of deaths being 82—viz., 49 males and 33 females, or 13·8 per cent. of the average number resident. Of the deaths one was due to pernicious anæmia, two each were due to cancer and epilepsy, three were due to influenza, five to pneumonia, eight to phthisis and other forms of tuberculosis, 10 to cardiac disease, 13 to general paralysis of the insane, 14 to senile decay, and the rest to other causes. During the year 74 patients were discharged as recovered, comprising 39 males and 35 females, or 12·5 per cent. of the average number resident. The deaths from general paralysis seem to have increased steadily during the last four years. Thus per 1000 resident patients the mortality from general paralysis was 2·6 in 1897, 5·1 in 1898, 10·0 in 1899, and 16·8 in 1900. The casualties during the year have been few and slight, a fact which reflects credit on the care and vigilance exercised by the staff among the patients. Continual effort has been made to keep as large a number of patients as possible usefully employed. Of the male patients 72 per cent., and of the females 88 per cent., were thus employed, which compares favourably with previous records and with other institutions. The general health of the patients has been good throughout the year. Diphtheria was contracted by a laundry-maid and to prevent the possibility of infection being carried from the patient by the asylum medical staff she was attended by a local practitioner. A difficulty such as this, adds Dr. Whitwell, “must continue to exist until the new isolation hospital is ready for occupation.” The water and gas supplies have been maintained in good condition and the new sewage works have proved satisfactory. The cost of maintenance per patient has risen somewhat during the year. The Commissioners in Lunacy state in their report that the best order prevailed in the wards, that the surroundings were cheerful and pleasant, and that the medical case-books were well kept.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6504 births and 4459 deaths were registered during the week ending Nov. 30th. The annual rate of mortality in these towns, which had been 19·7 and 19·4 per 1000 in the two preceding weeks, rose again last week to 20·3 per 1000. In London the death-rate was equal to 20·5 per 1000, while it averaged

20.2 in the 32 large provincial towns. The lowest death-rates in these towns were 9.9 in Huddersfield, 12.1 in Wolverhampton, 12.3 in Derby, and 13.0 in Plymouth; the highest rates were 24.4 in Preston, 24.6 in Manchester, 25.8 in Birkenhead, 26.3 in Birmingham, and 28.5 in Oldham. The 4677 deaths in these towns last week included 434 which were referred to the principal zymotic diseases, against 427 and 443 in the two preceding weeks; of these 434 deaths 143 resulted from measles, 79 from diphtheria, 61 from scarlet fever, 44 from "fever" (principally enteric), 44 from whooping-cough, 43 from diarrhoeal diseases, and 21 from small-pox. No death from any of these diseases occurred last week in Gateshead; in the other towns they caused the lowest death-rates in Brighton, Plymouth, Burnley, Bradford, and Hull, and the highest rates in West Ham, Norwich, Oldham, and Blackburn. The greatest proportional mortality from measles was recorded in Norwich, Manchester, Oldham, Blackburn, Huddersfield, Halifax, and Sheffield; from scarlet fever in Liverpool and in Salford; from whooping-cough in Leicester and in Swansea; and from diarrhoeal diseases in Derby. The mortality from "fever" showed no marked excess in any of the large towns. The 79 deaths from diphtheria in these towns included 40 in London, eight in West Ham, four in Portsmouth, three in Cardiff, three in Leicester, three in Liverpool, and three in Sheffield. Twenty-one fatal cases of small-pox were registered in London, but not one in any of the 32 large provincial towns. There were 427 cases of small-pox under treatment in the Metropolitan Asylums hospitals on Saturday, Nov. 30th, against 297, 368, and 396 at the end of the three preceding weeks; 123 new cases were admitted during the week, against 62, 113, and 141 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 3331, 3353, and 3336 on the three preceding Saturdays, had further decreased to 3278 at the end of last week; 320 new cases were admitted during the week, against 380, 376, and 379 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 445, 477, and 582 in the three preceding weeks, declined again to 534 last week, but were 105 above the corrected average. The causes of 35, or 0.8 per cent., of the deaths in the 33 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Nottingham, Salford, Bradford, Leeds, Sheffield, Hull, and in 14 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Blackburn, and Halifax.

#### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19.9 and 21.3 per 1000 in the two preceding weeks, further rose to 22.2 per 1000 during the week ending Nov. 30th, and exceeded by 1.9 per 1000 the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 17.5 in Greenock and 18.0 in Dundee to 24.1 in Glasgow and 28.0 in Paisley. The 706 deaths in these towns included 29 which were referred to measles, 21 to diarrhoea, nine to "fever," eight to diphtheria, seven to whooping-cough, and three to scarlet fever. In all, 77 deaths resulted from these principal zymotic diseases last week, against 72 and 85 in the two preceding weeks. These 77 deaths were equal to an annual rate of 2.4 per 1000, which was 0.5 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of measles, which had been 18 and 29 in the two preceding weeks, were again 29 last week, and included 23 in Glasgow and four in Dundee. The deaths from diarrhoea, which had been 23, 22, and 30 in the three preceding weeks, declined again last week to 21, of which 11 were registered in Glasgow, four in Aberdeen, and three in Dundee. The fatal cases of "fever," which had been 16, 12, and eight in the three preceding weeks, rose again to nine last week and included six in Glasgow and two in Paisley. The deaths from diphtheria, which had been nine and six in the two preceding weeks, increased last week to eight, of which five occurred in Glasgow. The fatal cases of whooping-cough, which had been three and six in the three preceding weeks, further rose last week to seven, and were all recorded in Glasgow. The deaths from scarlet fever, which had been eight and six in the two preceding weeks, further declined

to three last week and included two in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 190 and 177 in the two preceding weeks, rose again last week to 186, and were 26 in excess of the number in the corresponding period of last year. The causes of 26, or nearly 4 per cent., of the deaths in these eight towns last week were not certified.

#### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23.9 and 23.8 per 1000 in the two preceding weeks, further declined to 18.2 per 1000 during the week ending Nov. 30th. During the past four weeks the death-rate has averaged 22.4 per 1000, the rates during the same period being 20.6 in London, and 18.6 in Edinburgh. The 135 deaths belonging to Dublin registered during the week under notice, showed a decline of 36 from the number in the preceding week, and included seven which were referred to the principal zymotic diseases, against five, six, and nine in the three preceding weeks; of these, four resulted from diarrhoea, one from scarlet fever, one from whooping-cough, and one from "fever." These seven deaths were equal to an annual rate of 1.0 per 1000, the zymotic death-rates last week being 1.9 in London, and 0.5 in Edinburgh. The four fatal cases of diarrhoea showed a slight increase, the number in each of the three preceding weeks having been two. The 135 deaths in Dublin last week included 24 of children under one year of age and 42 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons were slightly below the number in the preceding week. Seven inquest cases and three deaths from violence were registered, and 40, or nearly one-third, of the deaths occurred in public institutions. The causes of seven, or more than 5 per cent., of the deaths in Dublin last week were not certified.

#### THE SERVICES.

##### ROYAL NAVY MEDICAL SERVICE.

STAFF SURGEON A. H. L. COX has been appointed to the *Rainbow*.

##### ROYAL ARMY MEDICAL CORPS.

Major R. N. Buist is holding himself in readiness to proceed to India for a tour of service, embarking on the transport *Plussy* about Dec. 10th. Surgeon-Lieutenant Mowbray Taylor, Volunteer Medical Staff Corps, is granted the temporary rank of Lieutenant whilst serving in South Africa. Major L. Haywood takes over medical charge of the station hospital, &c., at Gosport, from Major J. H. Nicholas, A.M.R. Lieutenant-Colonel D. Bruce is detailed for temporary duty in the War Office. Lieutenant-Colonel F. T. Wilkinson is held in readiness for South Africa.

Surgeon-General A. F. Preston, Acting Director-General of the Army Medical Service, is to resume the post of Principal Medical Officer on the Staff of the Duke of Connaught in Ireland on being relieved at the War Office by Surgeon-General W. Taylor.

##### VOLUNTEER CORPS.

*Artillery*: The Highland: Surgeon-Lieutenant R. G. Dick resigns his commission. *Rifle*: 2nd Volunteer Battalion the Welsh Regiment: Lieutenant Thomas Morgan Jones Powell resigns his commission and is appointed Surgeon-Lieutenant. 2nd Volunteer Battalion the Prince of Wales's (North Staffordshire Regiment): Brigade-Surgeon-Lieutenant-Colonel H. M. Morgan retires under paragraph 111 Volunteer Regulations, with permission to retain his rank and to wear the uniform of the battalion on retirement, vacating at the same time his appointment as Senior Medical Officer to the Staffordshire Volunteer Infantry Brigade. 4th (Donside Highland) Volunteer Battalion the Gordon Highlanders: Surgeon-Captain. A. Nicol to be Surgeon-Major.

##### MENTIONED IN DESPATCHES.

In despatches recently received from General Lord Kitchener to the Secretary of State for War the following names are mentioned:—Major T. G. Lavie, R.A.M.C., and Civil Surgeon W. S. Kidd who, though wounded early in the attack on Colonel Kekewich's camp at Moedwill on Sept. 30th continued at their duties many hours.

Staff Serjeant E. Fells, R.A.M.C., on the same occasion, for gallantry in looking for and attending to the wounded under heavy fire at Rhenosterfontein, Western Transvaal, Sept. 5th, 1901.

In a supplementary despatch from Major A. Chapman, who commanded troops at the attack on Fort Itala on Sept. 26th, Lieutenant T. E. Fielding, R.A.M.C., is mentioned as having been captured by the Boers (subsequently released) while attending to the wounded. The following note is attached to the despatch:—"Lieutenant Fielding, R.A.M.C., reports that nothing could exceed the kindness of General Chris. Botha to the wounded; it was only his presence and influence which restrained his burghers from robbing the wounded, and on several occasions he struck burghers for trying to do so."

#### SOUTH AFRICAN WAR NOTES.

A correspondent to the *Times* of Dec. 3rd sends a letter from a young officer in South Africa which deals with Colonel Benson's last fight. Referring to the action of Brakenlaage on Oct. 31st, the letter says: "All that night we were intrenching ourselves and bringing in our wounded, and to make matters worse it rained for three hours and our wounded had to be out in all the wet and cold. We did not get all our wounded in until after noon the following day and our R.A.M.C. doctors did work well; they were at it for 48 hours hard without a rest attending to the wounded. I must say the R.A.M.C. played the game, nothing could have been done more by them."

Captain J. Grech, R.A.M.C., and Civil Surgeons A. Cameron, R. Corfe, and R. V. Milnthorpe are returning to England in the steamship *Nubia*, which left Natal for England on Nov. 26th.

Major F. A. Saw, R.A.M.C., Captain C. O'C. Hodgins, R.A.M.C., and Civil Surgeons Summers, Rutherford, Goldsmith, Ackland, Hathaway, and Graham left Cape Town in the s.s. *Dilwara* on Nov. 28th.

Civil Surgeon F. F. McCabe, R.A.M.C., is reported missing, presumably prisoner at Doornkop (Nov. 28th.)

#### THE FOOT-SOLDIER'S BOOT.

The most important item of an infantry soldier's accoutrement is his foot-covering. The nation which gives its soldiers the best boots, said Marshal Saxe, has an immense advantage over its enemies, that of keeping the men always available for marching. Napoleon, also, attached the greatest importance to the foot-gear of his magnificent infantry. Each man carried two pairs of shoes in his knapsack in addition to those he was wearing, and, moreover, possessed several more pairs which were carried in the baggage-wagons. Writing to Prince Eugene the great Emperor said: "You know that in war the supply of shoes is always insufficient." In this connexion the famous dictum of Napoleon's conqueror may be mentioned. "The first requirement of a foot-soldier," said the Iron Duke to an inquirer, "is a good pair of boots, the second is an extra pair, and the third a pair of spare soles." A foot-soldier without boots is as useless in a campaign as a horse-soldier without a horse. But in each case it is not sufficient to supply a man with a good article; he must also know, or be taught, how to treat it. In a recent paper,<sup>1</sup> Surgeon-Major Berthier of the French army gives a description of what would seem to be an almost ideal boot for the fantastically named *fantassin*, or French foot-soldier, and at the same time lays down apparently unexceptionable laws regarding the *entretien* of his invention. Surgeon-Major Berthier's *brodequin haut* is eight inches in height without reckoning the heel, and is closed in front by two flaps which are laced in a novel manner. Below on either side there are four eyelets, which should be tightly drawn together over the instep, while above there are five pairs of hooks and two eyelets which may be approximated tightly or loosely according to circumstances. Apparently two separate laces are required for each boot. The inventor does not believe in Meyer, whose soles and uppers are neither of them "rational." He thinks that the time has come to decline to be hypnotised by the Zürich model. Meyer refused to accept the plan now adopted by shoemakers of gauging the shape of their clients' feet on sheets of paper, but it is difficult to see a rational reason for the refusal. Meyer wants to manipulate the great toe on theoretical lines, but, says

Surgeon-Major Berthier, we know now that the trifling abduction of that digit is *une déviation normale*. A great many points having reference to the foot-covering of soldiers are admirably elucidated in this paper, but the writer is scarcely convincing regarding the *raison d'être* of heels. The heel of the military boot now used in France is 1.20 inches in height. This elevation, according to Surgeon-Major Berthier, "facilitates marching by diminishing the muscular work demanded at each uprising on the toes. At the same time a certain inclination of the trunk forwards is rendered necessary which is favourable to progress, forcing the legs to bend and lengthening the step." The higher the heel the easier to walk would seem to be the corollary of this proposition; but, after all, nature may be trusted to know best. To the writer's final decision no exception can be taken: "When troops are moving men always fall out in great numbers from foot-soreness. It behoves us to search for prophylactic measures to prevent this, seeing that foot-soreness is avoidable."

#### THE FEVER SEASON IN SOUTH AFRICA.

While there is no reason for adopting pessimistic views, or indulging in forebodings as to what is likely to be the medical history of our troops in South Africa during the forthcoming hot season, it is only wise and right to take all practicable precautions against a possible increase of enteric fever. This is a time for increased vigilance in regard to the sanitation and cleanliness of camps, for the provision of good sources of water-supply, and for the sterilisation of that water about which there is any suspicion of contamination. The laying down of rules and regulations is not enough, the regular, systematic, and rigid enforcement and application of them by a sanitary police are likewise necessary. Camps should be kept scrupulously clean and the sites changed from time to time and always on the outbreak of disease, or on there being any evidence of the soil having been fouled. Great care should be used about the disposal and disinfection of excreta—whether solid or fluid—and about the burning of refuse. It may be said that all this is so well known that the publication of it is merely the printing of platitudes, but it does not follow, unfortunately, that such matters are as carefully and well attended to as they might be.

#### DEATHS IN THE SERVICES.

Surgeon-General Robert Harvey, C.B., D.S.O., LL.D., Director-General of the Indian Medical Service, at Bombay, aged 59 years. He entered the service in 1865 and served with the Bhootan expedition in 1865-66 (medal with clasp). He also served with the Lushai expedition in 1871-72 (mentioned in despatches, clasp). He was with the Central India Horse from 1871 to 1875, and was civil surgeon at Simla from 1876 to 1877, when he became Surgeon-Major. He was appointed Sanitary Commissioner of Bengal in 1878, and was promoted to the rank of Brigadier-Surgeon in 1889. He was Principal Medical Officer of both the Miranzai expeditions of 1891 (mentioned in despatches, clasp, and the D.S.O.). He also accompanied the Hazara expedition in 1892 as Principal Medical Officer, being appointed Deputy Surgeon-General. He was Inspector-General of Civil Hospitals, Bengal, 1893-94, and was President of the first Indian Medical Congress, held in 1894. He was promoted Surgeon-Major-General in 1895 and appointed Principal Medical Officer to the Punjab Forces. He was awarded the Jubilee medal in 1897 and made C.B. in 1898. He was appointed Director-General of the Indian Medical Service in the same year.

#### THE SOLDIERS' AND SAILORS' FAMILIES ASSOCIATION.

Her Majesty Queen Alexandra has signed a portrait of herself for presentation to Mr. J. S. Wood, who originated and organised the Great County Sale as a "response to the Princess of Wales' Appeal" on behalf of the Soldiers' and Sailors' Families Association which has resulted in £20,463 being collected for those "left behind." Accompanying the framed portrait was a silver casket containing an address of thanks in a bound volume with the signatures of Princess Frederica of Hanover, the Secretary of State for War, the Commander-in-Chief, Lady Raglan, Lady Fremantle, Lord Arthur Hill, Colonel Gildea and eighty others, representing the stallholders in all counties who had subscribed to this testimonial to Mr. Wood, who has been instrumental in collecting over £200,000 for charity during the past 26 years.

## Correspondence.

"Audi alteram partem."

THE PUBLIC HEALTH AUTHORITIES AND  
THE RESPONSIBILITY OF DIAGNOSIS  
OF INFECTIOUS DISEASES.

To the Editors of THE LANCET.

SIRS,—I beg to inclose for publication a communication addressed by me to the Local Government Board and the reply. According to the Local Government Board it is not the duty of the public health authorities to assist in diagnosis or to take part of the responsibility of diagnosis of infectious disease unless they think it necessary to do so. This, to my mind, is a very unfortunate, though not unexpected, reply to my questions. I need scarcely urge that if the authorities are not in the habit of assisting in diagnosis they will find it very difficult to get the opportunity to do so when panic makes them think it necessary. Up to the present no provision is made, nor is there any indication of any provision being about to be made, for discovering and dealing with what I might call the creator of epidemics—the doubtful case. It is not even notifiable; surely this at least ought to be done.

Indeed, Sirs, it would almost seem as if the public health officials, from the Local Government Board downwards, were anxious not to attack epidemics too thoroughly lest the *raison d'être* of their own existence should vanish. This cannot be so, but still, what are the facts? The doubtful case is the *fons et origo* of probably all epidemics; no stone should be left unturned, no opportunity should be missed to get hold of it, and yet the authorities say, "No, diagnosis is not our duty." They say to the practitioner, "Show us the disease and then we will deal with it," like the sham rat-catcher in the old story, who, having dined gratuitously, says to the innkeeper, "Now trot out your rats and I will kill them." He did not undertake to catch the rats, he only undertook to kill them in exchange for his dinner. I think the position of the public and that of the innkeeper are somewhat similar. Well, it is the fault of the public now if they do not get matters put right. You cannot expect a public department to put themselves right, but they are always ready to veer round and to sail with the wind of public opinion when that opinion expresses a real need.

What I urge is a change of the critical irresponsible attitude of the authorities towards medical practitioners. Let them make it the duty of medical officers of health when possible and if requested by a practitioner to visit all doubtful cases of infectious disease and to share the responsibility of diagnosis. Let the medical practitioners be made to feel how grateful the authorities will be for their assistance in notifying all doubtful cases, how willing they are to place their medical officers at the service of the practitioner, and how ready they are to take the responsibility of the results of diagnosis in all doubtful cases. And, further, let the authorities send a circular to every medical practitioner requesting his aid and offering all I ask in the right spirit. Most of the medical officers of health have had experience of infectious diseases and are ready and willing to do the work when those behind them go at it in a whole-hearted manner. An epidemic of small-pox is to be expected in the spring, everything at present is pointing in that direction. Why should not the authorities do all they can to prevent the festivities of the coming summer being marred, perhaps ruined, by a small-pox scare? What I humbly urge is a most potent prophylactic and will not, I trust, be neglected.

I am, Sirs, yours faithfully,

4, Bryanston-street, Nov. 30th, 1901.

DAVID ROXBURGH.

To the President of the Local Government Board.

SIR,—I venture to ask for an expression of your opinion—as the highest administrative authority on matters relating to public health—(a) as to whether a medical practitioner is entitled to ask the assistance of the medical officer of health in the diagnosis of infectious disease; and (b) whether it is the duty of the medical officer of health to take part of the responsibility of diagnosis when he is asked to do so. I think, Sir, that the subjoined correspondence and press notices in the leading medical journals will, in your opinion justify the view that the matter is one of serious importance and also that it is one which calls for a definite declaration by the Local Government Board for the

guidance of medical practitioners on the one hand and medical officers of health on the other. In considering the matter I would ask you to dismiss from your mind the trivial details (published only to show how the question arose) which called forth the expression of Dr. Wynter Blyth's opinion and deal with the question in its broad aspect as to the ultimate effect of the decision you may see fit to arrive at upon the general public in so far as they are affected by the control the local authorities have over infectious disease. There are a few points I would venture to advance for your consideration—(a) In relation to the question at issue; (b) in relation generally to the duties of a medical officer of health.

Firstly, Dr. Blyth declares, I presume with some authority behind him, "that diagnosis of cases is no part of the duty of a medical officer of health." If this be so, what course, Sir, is open to a medical practitioner when he finds himself face to face with a doubtful case of small-pox? He is not certain, cannot as in this instance be certain, of his diagnosis. The patient comes to him only because her beauty is marred by a few "spots" on her face. She is quite well enough to go about her ordinary work. I contend, Sir, that it is not right in these cases that in a town any man should act solely on his own opinion—the results of error either way are too serious to the patient if he sends her to the small-pox hospital when she has not got small-pox, to the public if he permits her to wander about when she has. In whose interest is it that diagnosis in such a case shall be made as certain as possible? Not the patient's, as this might mean suspension of employment, perhaps loss of a situation. Is it probable that the patient will pay for a consultant when the case is so mild that he scarcely feels ill? I think not. The interested party, I submit, is the public; the public should provide the consultant. What is the position of the medical practitioner? He is only under legal obligation to notify: cases he knows to be small-pox; if he is in doubt he is under no such obligation. If he considers the public and sends a doubtful case to the small-pox hospital it is at considerable risk to himself. If the case turns out not to be small-pox and contracts small-pox in the hospital, he is, I think, open to an action for damages at the instance of the patient. Is it to be expected, then, that he will notify doubtful cases? In the event of such an error his position would be quite different when backed by the opinion of the medical officer of health. If Dr. Blyth's position is correct he cannot refer the matter to the medical officer of health because "diagnosis is no part of his duty." The only course he can adopt—and as a matter of fact does adopt—is to leave these doubtful cases unnotified to wander about and disseminate the disease.

Secondly, in relation generally to the duties of a medical officer of health it may be urged that if the medical officer of health is to assist in diagnosis the additional work will materially alter his duties. I would here point out that both the *British Medical Journal* and THE LANCET say that he cannot act as a consultant for reasons which, in so far as they are stated, seem to me unsound. But, Sir, in considering his duties I would ask you to reflect upon how these duties have changed within the last 20 years or so. Statistics are now in the hands of a trained clerk, water and drainage are the domain of the engineer; sanitary matters in relation to dwellings existing or to be built are now so well understood that it must only be occasionally that the surveyor or sanitary inspector requires the support of the medical officer; foods and drugs are the realm of the chemist or the specially trained inspector. These and other duties, although always within the range of the activity of a medical officer of health, are in practice passing more and more into the hands of others and it always must be so. Such matters, while bulking large in the accomplishments of a medical officer of health, must in actual practice gradually demand less and less of his time. In the sphere of infectious disease, its diagnosis and prevention we find, I most humbly submit, new—if they be new—duties and responsibilities which a medical officer of health can neither evade nor relegate to others (except medical deputies). To my mind, of all his duties as they exist to-day the diagnosis and isolation of cases of infectious disease are the most important and the most urgent.

The numbers of "doubtful" cases will always be few and would never seriously interfere with his other duties (even if they did I fail to see how in the interests of the community he could be better employed). They would, however, materially increase in number to the great advantage of the public if medical practitioners were informed that when possible it was the duty of a medical officer of health, it asked to do so, to assist in the diagnosis and take part of the responsibility of the results of diagnosis in all doubtful cases of infectious disorders.

I apologise for the length of this communication, but I feel the matter is of serious importance; that the public health officials are naturally desirous of pushing the responsibility of diagnosis wholly on to the medical practitioner; and that medical practitioners must take the only course open to them—viz., that of leaving "doubtful" cases to wander about unnotified to the detriment and misfortune of the general public. I respectfully ask your permission to publish your reply to my questions.

I am, Sir, your obedient servant,

4, Bryanston-street, Oct 16th, 1901.

DAVID ROXBURGH.

Local Government Board, Whitehall, S.W.,  
9th November, 1901.

SIR,—I am directed by the Local Government Board to advert to your letter of the 16th ultimo and to state that they are not prepared to say generally that it is the duty of a medical officer of health to visit a doubtful case of infectious disease whenever he may be requested to do so by the medical practitioner in attendance with a view to assisting him in the diagnosis. The responsibility for the diagnosis as regards the duty of notifying must rest with the practitioner in attendance on the case, but the Board are advised that cases not unfrequently occur in which for the due carrying out of the medical officer of health's prescribed duties under Sections (1), (2), (4), and (6) of Article 18 of the Board's General Order of the 8th December, 1891, a consultation between the medical officer of health and the medical practitioner in attendance is desirable. A personal examination of the patient, however, can only be made by the medical officer of health with the consent of the patient or that of the persons in charge of him. The Board believe that medical officers of health are usually found willing to assist medical practitioners in the diagnosis of suspected cases of infectious disease where danger to the public health is threatened, and they are advised that much benefit is likely to result from such co-operation.

I am to add that where the disease which is suspected is one of a

<sup>1</sup> Times, Oct. 8th; THE LANCET and Brit. Med. Jour., Oct. 12th.

highly infectious and dangerous nature it would be open to a medical officer of health, if authorised by his sanitary authority, to call in, with the consent of the patient and of his medical attendant, an expert having special knowledge of the disease in question with a view to arriving definitely and promptly at a decision. The Board are advised that a sanitary authority are empowered to pay a reasonable fee for such expert advice.

Dr. Roxburgh.

I am, Sir, your obedient servant.

JOHN LITHBY, Assistant Secretary.

## THE ETIOLOGY OF ECLAMPSIA: A CRITICISM.

To the Editors of THE LANCET.

SIRS.—The pathology of eclampsia is at the present time so obscure and indefinite that the leading article on this subject in THE LANCET of Nov. 2nd, p. 1206, is of special interest. Our knowledge of the condition has been but little, if at all, increased by some recent discussions. It appears to me that apart from the special difficulty of the question itself a great deal of the confusion is due to the wilful manner in which the etiology of eclampsia has been entangled in misguided speculation. How futile many of these speculations may be seen by a comparison of some of the theories which have been advanced. Whilst one writer concludes that cerebral anæmia is an essential factor another maintains that cerebral hyperæmia is a prominent factor. These and many other "theories"—all differing one from another—resemble each other very closely in their want of scientific basis. In a paper recently read before the Obstetrical Society the writer concluded that eclampsia was probably due to the formation of multiple thrombi, and he was not afraid to go farther and suggest that saline fluid when transfused probably dissolved these thrombi. So far as I was able to gather, these remarkable deductions were based on his observation that in two cases the patients lost less freely than usual and that some difficulty in transfusing was caused by blood-clotting in the cannula. This theory was held to be confirmed by some phenomena occurring after the treatment of aneurysm by gelatin injection and by the cerebral and other hæmorrhages so commonly found in cases of eclampsia post mortem. The suggestion is no better and no worse than many others, yet it illustrates the extraordinary facility of hypothesis on this subject, and it would perhaps be more consonant with scientific method if we were to exclude mere "views" and "theories" and to confine ourselves to observed facts. In the discussion of this paper one of the most serious contributions dealt almost entirely with cases of albuminuria in pregnancy, the question of fetal mortality in albuminuric cases, and with other matters which, however interesting in themselves, appear to be far removed from the subject of eclampsia, and in a discussion of this question serve only to add to the existing confusion. Other speakers were thus attracted to include in their remarks much that would have been more pertinent had the subject been renal disease in pregnancy. I think that this attitude, which appears to be generally adopted, is extremely unfortunate, and it is very unlikely that any real progress in the study of eclampsia will be made until certain necessary limitations are more fully appreciated. Whatever the cause of eclampsia may be, I take it that the word has been invented to describe a certain condition occurring during pregnancy, labour, or in the early puerperium. There can be little doubt in the minds of those who have observed many cases that the condition does deserve a special name—that it is most distinctly *sui generis*. Few diseases have more marked clinical features. Let me briefly indicate a few of the characteristic points as seen in a recent case. The patient was a primigravida, 28 years of age; the pregnancy had been normal and the patient felt well. She was safely delivered of a healthy infant at full term, and when her medical attendant left at 9 A.M. her condition was apparently quite good. About noon she complained of headache, became apathetic, and at 3 P.M. she had a convulsion and became comatose. Her condition was soon typically eclamptic, and at 8.30 she had her last convulsion, there having been altogether 11 convulsions in this period of five and a half hours. The urine was loaded with albumin. The next morning the patient was much better, the urine contained one-fourth albumin on boiling, and on the following day she was practically well, the urine only containing one-twelfth albumin; this entirely disappeared in two days. This, of course, was a light case, but it serves to emphasise

the distinct features of eclampsia—rapid onset with rapid and remarkable recovery in those cases that are not quickly fatal. Unfortunately we have allowed one element—the albuminuria—to take such a prominent position that renal disease is always intruding itself into the discussion and preventing our appreciation of the problem to be solved. I venture to assert that nothing can well be more unlike a real primary nephritis than such a case as the above. Have we ever seen primary renal disease, with the urine loaded with albumin, appear and disappear in the course of a few days, leaving the urine normal and the patient not merely convalescent but, as regards the disorder, completely recovered?

If confusion is to be avoided and the etiology of eclampsia is to be scientifically demonstrated I think that the following limitations must be rigorously observed: (1) the term "eclampsia" when used should not be allowed to include cases of convulsions where renal disease exists or there is reason for suspecting its existence; and (2) the term "eclampsia" should only be allowed to include those cases presenting the cardinal signs and in which the renal affection is but an incident in the attack.

Renal disease with uræmia may, and does, occur in pregnancy, and if we are to consider these eclamptic then there is no good reason for using the term at all. If the renal part of the disorder is really the essential feature of eclampsia it would be better to describe the conditions as a special form of nephritis. On the other hand, for the reasons intimated above, I think that the course of eclampsia and its clinical characters completely exclude its attribution primarily to renal disease. If eclampsia is to be confounded with any other disorder then I suggest that epilepsy is much nearer to it than nephritis. The importance of this differentiation between nephritis and eclampsia can best be appreciated when we recognise the character of some of the fatal cases of "eclampsia." I have seen more than one post-mortem report in a case of "eclampsia" where the necropsy showed the presence of well-marked and chronic nephritis. In such cases I submit that the term "eclampsia" is quite inadmissible. The patients died from uræmia due to nephritis aggravated by pregnancy; but the fact that they were pregnant should surely not lead us to turn "uræmia" into "eclampsia."—I am, Sirs, yours faithfully,

RALPH VINCENT, M.D., B.S. Durh., M.R.C.P. Lond.,

Late Senior Resident Medical Officer, Queen Charlotte's Lying-in Hospital, London.  
Harley-street, W., Nov. 26th, 1901.

## THE PROPHYLAXIS OF DIPHTHERIA.

To the Editors of THE LANCET.

SIRS.—My attention has just been drawn to a review in THE LANCET of Nov. 2nd (p. 1202) of the October number of the *Journal of Hygiene* in which you refer to my article on diphtheria. In this review you represent me as concluding that it is inexpedient to press the isolation of persons who are harbouring in their throats the bacillus of diphtheria but who present no other indications of the disease. As this remark gives, I think, an erroneous impression of my views on the subject you will no doubt permit me to correct it. I do, indeed, very strongly urge the isolation of these people, and this is now being systematically carried out at my suggestion both at Cambridge and at Colchester, where isolation homes entirely for them have been opened. I believe that these healthy people who carry about diphtheria bacilli are largely responsible for the spread of diphtheria and form the links which carry on the infection from one outbreak of the disease to another. But while I am anxious that all these people should be isolated I believe that it can be more thoroughly done by voluntary means than by compulsion, and I am opposed to the notification of such persons as cases of diphtheria. Experience has shown that the voluntary system will work in the towns mentioned, little difficulty having been met in persuading parents to send their children to the isolation home. The difficulty arises in the case of those in whom the bacilli persist for an unusual length of time, and every effort is now being made to find some way of freeing them from their dangerous parasites. The truth is that the local antiseptic treatment of throats which harbour diphtheria bacilli is at present very ineffective, and until some better method is discovered I cannot agree with you

that local antiseptic treatment can take the place of isolation.

I am, Sirs, yours faithfully.

LOUIS COBBETT.

Pathological Laboratory, Cambridge, Nov. 28th, 1901.

## THE DIRECTION OF HAIR ON THE HUMAN ARM.

To the Editors of THE LANCET.

SIRS,—Referring to Dr. Walter Kidd's letter in THE LANCET of Nov. 30th, p. 1531, it may be worthy of record that his theory is not of universal application for the following curious reason. The Mahomedan religion is divided into two principal sects, the Sunnites and the Shiites. The members of these sects can be readily discriminated by the fashion in which the hair grows on their arms, for while on those of the Sunnites the growth turns downward from shoulder to wrist on the anterior side and upwards from wrist to shoulder posteriorly, the hair on Shiite arms presents the contrary appearance on both sides of the arms. This singular divergence is produced by the manner of washing their arms as prescribed by the tenets of the sects respectively. For while Sunnites hold it orthodox to stroke their arms after washing them from shoulder to wrist on front and from wrist to shoulder on the back, the Shiites abhor this practice and stroke their arms in the opposite ways, and hence the two directions in which the hair is seen to grow on the arms of the two sects.—I am, Sirs, yours faithfully,

Ealing, Nov. 30th, 1901. GEORGE SHERRINGTON-MORRIS.

## THE SAFETY OF CHLOROFORM IN MIDWIFERY.

To the Editors of THE LANCET.

SIRS,—May I crave space to add to the reasons given by Sir William Mitchell Banks and Dr. E. Malins—in THE LANCET of Nov. 16th (p. 1323) and 30th (p. 1529), 1901, respectively—for the immunity from death under chloroform in midwifery practice—viz., the age and vigour of the patients, their position on the left side, the reflex influence of the uterine contractions, and the hopefulness of relief from pain—the not unimportant fact of the hypertrophy of the left ventricle which the heart of the pregnant woman undergoes, in obedience to a well-recognised physiological law, to render it equal to the extra work of driving the blood through the foetal circulation!

I am, Sirs, yours faithfully,

Watton, Norfolk, Dec. 2nd, 1901. H. MALLINS, M.B. T.C.D.

## FRIENDLY SOCIETIES AND THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS,—From the decision of the General Medical Council on Friday last in the Yarmouth case are we to infer that it is unprofessional to act as medical referee to the Liverpool Victoria Legal Friendly Society (which is a life insurance company) because it is associated with the National Medical Aid Company (which is a canvassing society)? or whilst refusing to act as surgeon to the National Medical Aid Company are we allowed to examine cases for the Liverpool Victoria? Other insurance companies have these so-called clubs, and I think that the justice of the matter would be met if practitioners were allowed to examine cases for life insurance but prohibited from acting as medical officer to any society or association which systematically canvasses for patients. The two societies have distinct offices, and whilst repudiating one I see no reason why one should not act for the other.—I am, Sirs, yours faithfully,

EDGAR DU CANE, B.A., M.B. R.U.I.  
Swindon, Dec. 2nd, 1901.

To the Editors of THE LANCET.

SIRS,—With the voting paper received from the General Medical Council is sent a copy of notices. No. III., which deals with association with medical aid societies, is worded as follows: "That the Council strongly disapproves of medical

practitioners associating themselves with medical aid associations which systematically practise canvassing and advertising for the purpose of procuring patients." Surely, if the Council so strongly disapprove, why do they not carry their disapprobation to its logical conclusion and pass a law prohibiting it altogether? There would be no lack of support from the rank and file of the profession. I am amongst the offenders, but why should I give up the £60 per annum, which my appointment brings me in, in order that my opponent should reap the benefit of my endeavour to carry out the wishes of the Council? It is not to be expected and would not be business-like.

I am, Sirs, yours faithfully,

Nov. 29th, 1901.

PRACTITIONER.

## AN ELECTRO-THERAPEUTICAL SOCIETY.

To the Editors of THE LANCET.

SIRS,—May I ask for your kind assistance in making known to the profession that it is intended to form an electrical society for duly qualified medical practitioners who are interested in the application of all forms of electricity to disease. Any practitioners willing to give their support to such a society are requested to send their names to the undersigned.

I am, Sirs, yours faithfully,

CHISHOLM WILLIAMS.

20, Bedford-square, W.C., Dec. 2nd, 1901.

## OUR INCOMPLETE VACCINATION ACT.

To the Editors of THE LANCET.

SIRS,—I have come to the conclusion, after careful study, that the principle which governed the inception of the last Vaccination Act will not be completely applied till successful vaccination certification is put on a parallel basis with infectious disease notification, so that all medical practitioners would become *ipso facto* vaccinators for the public. This would nationalise vaccination and enlist the active assistance of the entire profession. To leave matters on their present footing is no more logical than it would be to exclude small-pox notification itself. I would retain the public vaccinator as a reserve persuasive force, his services to come into operation when the sixth month after birth is reached without due certification. The fee should be paid on a similar but unified system to that now prevailing, distances being calculated from a fixed point in each area only, without reference to the certifiers' residence.

I am, Sirs, yours faithfully,

ARTHUR WADDELL, M.D. Glasg.

Potters Bar, Dec. 2nd, 1901.

## MEDICAL BIBLIOGRAPHY.

To the Editors of THE LANCET.

SIRS,—The discontinuance of *Bibliographia Medica* would be a calamity to all students of medicine. Is it not possible for a combination of the great medical institutions and societies in this and other countries to avert such a disaster which a recent circular says may happen to us?

I am, Sirs, yours faithfully,

L. M. GRIFFITHS.

Bristol, Dec. 2nd, 1901. Hon. Librarian, Bristol Medical Library.

## AMERICAN DENTISTRY.

To the Editors of THE LANCET.

SIRS,—May I call your attention to an article in the November *Review of Reviews* on the above subject? Had it not been for one or two paragraphs I should not have troubled you about such barefaced quackery. Amongst other things it is stated that six medical practitioners were attended in one week at a branch of the American Dental Institute—an institute whose seeming superiority is set forth in no feeble language. Though unprofessional readers may be gulled by such articles it is surprising that even many medical men are quite as easily influenced. "American dentistry" seems to have a great fascination, and though it is obvious that it possesses no claims to superiority over dentistry as practised over here, yet even medical men who ought to know better are lured by the magic expression

"American." We Americans practising in this country hock on the terms "American dentistry," "Teeth on the American system," and such like expressions as advertising lodges. How long will this be allowed?

I am, Sirs, yours faithfully

AMERICAN DENTIST.

## NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

### *The Health of Bombay and the System of Death Registration in India.—Municipal Improvements.—The Incidence of Plague.*

IN the present state of the system of registration of deaths in Bombay it is almost guess-work correctly to apportion the deaths to the different diseases. Phthisis, for example, fluctuates week by week in a most extraordinary fashion and would appear at times to be epidemic. The present death-rate of the city is 53.60 per 1000, the deaths for the past week having been returned at 830. Of this number there were 173 deaths registered as due to plague and 113 as due to phthisis. There is practically no cholera or small-pox. To improve the system of recording deaths it is now proposed to make it the duty of the nearest relative to produce a certificate from a medical man. It is also proposed to establish a certain number of public free dispensaries and for the officers in charge of these to act as registrars. Many of the private charitable dispensaries have promised to coöperate. When it is remembered that for nearly all over India the causes of deaths are just those which the relatives choose to name, and that perhaps not 5 per cent. of the deaths are certified by qualified medical men, it will be understood how worthless most of the statistics are. The only calculable feature in them is that the same errors continue year after year so that for local purposes some sort of comparison can be instituted. When the death is not due to some easily recognisable disease, such as cholera, or small-pox, or phthisis, or dysentery, it is generally put down to fever, so that the return of about 5,000,000 deaths annually from fever is not surprising. The same crude system is in vogue in Calcutta, in Madras, and in other towns. In these supervised places the number of deaths may be fairly correct, whilst the causes remain problematical. In the country districts the total number of deaths is liable to great error.

Calcutta, as I have already reported, is making arrangements to have a constant supply of filtered water, and the drainage of the suburban areas is also receiving attention. The conservancy has considerably improved lately and the streets are much cleaner. The tramway company is proceeding actively with an electric service which is expected to commence with the new year. Madras, on the other hand, seems asleep. There is no scheme afloat for any general improvement. The drainage is bad and the water-supply is suspicious. The roads are as bad as they can be, and the hackney carriages are the "show" of the world. In Bangalore city some attempt has been made to open out the congested parts, and in Ootacamund the catchment areas of the water-supply have been safeguarded.

The general plague figures for India have not been published, but local reports show that the disease is spreading in the Punjab and at Poona. In Calcutta and the Bengal districts there is little change.

Nov. 14th.

## BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

### *Corporation Bill: Sanitary Clauses.*

THE Corporation Bill at present before the Birmingham City Council is causing considerable excitement. A public meeting is to be held to discuss the many proposals set forth, and to certain of them decided opposition is expected. Thus, the laundry clauses enact that the medical officer of

health may by notice require to be furnished with a list of the customers of any person earning a livelihood or deriving gain from the washing or mangling of clothes during the past six weeks. Payment will be made at the rate of 6*d.* for every 25 such names and addresses, but no payment is to exceed 3*s.* The penalty for non-compliance is 40*s.* and a daily penalty not exceeding 20*s.* Another proposal is that when any scholar who attends any school within the city shall be known to be suffering from any infectious disease the principal or person in charge of the school shall forthwith send notice to the medical officer, and shall furnish to him at his request a list of the pupils attending the school and their addresses. For the purposes of this scheme of notification whooping-cough will be included among infectious diseases. No person being the parent or having the care or charge of a child who has been or is suffering from infectious disease shall, after a notice from the medical officer that the child is not to be sent to school, permit such child to attend school without having procured from the medical officer a certificate that there is no risk that such child will communicate his disease to others. The certificate shall be granted free of charge upon application. The clauses in respect to dairies are equally stringent. When it shall be certified to the corporation by the medical officer that the outbreak or spread of infectious disease is in his opinion attributable to the milk supplied by any dairyman the corporation may require such dairyman to furnish them with a list of the names and addresses of all his customers within the city. Another section provides that a list of all the farms, dairies, or places from which the dairyman receives his supply may be demanded by notice. Also every dairyman shall notify to the corporation or to the medical officer all cases of infectious disease among persons engaged in or in connexion with his dairy. The penalties for non-compliance are throughout to be the same as those which I have mentioned under the laundry clauses. They are, in my opinion, calculated to prevent the spread of infectious disease in many directions.

### *The General Hospital and Infectious Cases.*

The prevalence of scarlet fever has led in a number of instances to its introduction into the wards of the General Hospital through the medium of patients' friends. A notice has therefore been issued by the authorities that all visitors shall be prohibited for a time—except in very exceptional and urgent instances. Another difficulty before the Medical Committee is the method of dealing with infectious cases in the out-patient room. It not infrequently happens that an out-patient is found to be suffering from scarlet fever or some infectious disease. The committee feel the necessity of providing isolation in such cases and suggest that some separate room should be provided where such patients can wait until removal is possible.

### *The University Students.*

This has been a week of dinners. On Nov. 26th the annual dinner of the medical students was held under the Presidency of Dr. T. Stacey Wilson. The proceedings were enthusiastic and the meeting was well attended by the students and professors.—The 27th witnessed a meeting somewhat less regular in character, a dinner of the football club, the unforeseen expenses of which are said to be giving cause for thought.—The dental school held a dinner on the 29th at which occasion was taken by Mr. Humphreys to remark upon the good sense of the University in granting a dental degree. The professional status of the dentist, he said, had been raised thereby and Birmingham had set a proud example to other universities in this respect. It was stated that no fewer than 40 applications had been made by men holding good and influential positions requesting to know if the degree could be obtained without going through the curriculum.

### *The Clinical Board and Post-graduate Study.*

Arrangements have been made by the Clinical Board for holding a double series of demonstrations at the General and Queen's Hospitals for the benefit of those practitioners who purpose presenting themselves for the modified examination for the M.B., B.A. Birmingham, next June, and for others who may wish to see some hospital practice. The fee for the double series is five guineas and applications should be made to Mr. W. F. Haslam, 54, Newhall-street.

Dec. 3rd.

## MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

*Poisoned by Roburite Fumes.*

THERE was a mysterious poisoning case recently at Ince, near Wigan. A man, his wife, and five children were taken to the Wigan Infirmary in a critical condition, owing, it was presumed, to some irritant poison. It was thought at the infirmary, however, that the symptoms were more like those from the inhalation of noxious fumes, an opinion now verified. It appeared that the day before they were seized with illness a neighbour saw the man's wife crushing a brown substance into a small tin, and she explained that she was going to pepper the beds and bedclothing, "as we are nearly worried," and she was going to put some on the floor to kill the cockroaches. As she and her family were so nearly killed it may be presumed that the fleas and cockroaches were slain. The woman admitted that she had "mixed a quantity of roburite with some insect powder and scattered it about the beds and clothing for the purpose of killing the insects." She was at first afraid of stating this, fearing that she had done wrong. A somewhat similar case occurred a few years ago at Huyton.

*The Manchester Cancer Hospital.*

The annual meeting of the Cancer Pavilion and Home, as it has hitherto been called, was held on Nov. 26th. Mr. Alfred Hopkinson, the Principal of the Owens College, presiding. It was resolved, in order to recognise the great services rendered to the institution by the late Chancellor Christie—for without his generous help it could not have been founded—to change the name to "The Christie Hospital." The wards have recently been extended, so that it has been possible to deal with more patients than formerly—viz., 108 in-patients and 100 out-patients, against 88 and 91 in the previous year. Owing to this extension and to the provision of Roentgen ray apparatus which had been purchased at the urgent request of the medical staff the hospital is somewhat in debt, but the fact did not seem to cause any alarm. The medical report stated that the youngest patient admitted was 16 years of age and the oldest 81 years, the average age being 52.1 years. During the year 42 patients who were admitted in a hopeless stage of the disease and who could not be properly treated at home have been given an abode in the home for the remaining period of life. At the request of the chairman Dr. R. B. Wild gave a short account of the Roentgen apparatus. He said that the results had been satisfactory in arresting the disease in some cases that were going from bad to worse. "He thought that in this and other ways some portion of the hospital funds might be used in investigating the causes and possible cures for the scourge of cancer." This suggestion was well received, the chairman saying that he, in common with many of the subscribers, felt strongly that one of the objects of such a hospital was the prosecution of such investigations. "He was gratified to find that the association of the hospital with various institutions such as the Owens College was growing."

*Manchester Housing Scheme.*

The Housing Sub-committee of the Sanitary Committee of the Manchester City Council, have just shown a very sensible spirit. Some time ago plans were adopted for model cottages to be built at Blackley, one of the suburbs, to provide accommodation for some of those who were dispossessed by recent changes. These plans brought strong adverse criticism, one of the points being that the arrangement would condemn many of the cottages to be sunless. New plans have been adopted, in many respects following those of model cottages built at Leek, the chief additions being a bath-room on the ground-floor and behind the kitchen fireplace. This room is to be made available for washing purposes generally. There is also to be a third bedroom. The only fear is that the cottages will be too costly to allow of low rents. The plans have yet, however, to run the gauntlet of the city council and the Local Government Board.

*Hospital Saturday Fund.*

The annual meeting of the Hospital Sunday and Saturday

Fund was held in the Manchester Town Hall yesterday. In 1900 the committee were able to distribute £1000 more than in the previous year, though there were large calls on the public for other purposes, and this year the total of the two funds, £8180, is an increase of £1226 over last year. This increase is gratifying, but, as the chairman of the committee reminded the meeting, Manchester stands very badly as compared with other large towns. There is a proposal to build a convalescent home which will cost at least £10,000, towards which a substantial contribution has been promised and the gift of a site has been offered.

Dec. 4th.

## WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

*Water-supplies.*

IN spite of the rainfall in many parts of South Wales and Monmouthshire being far above the average rainfall in England and Wales, and although there are ample gathering grounds, there are still many populous districts which are very inadequately supplied with potable water. At Newport the supply is not constant even now and is only available between 7 A.M. and 6 P.M. At Abertillery, a mining district in Monmouthshire the population of which has increased from 11,000 in 1891 to 22,000 in 1901, is a reservoir with a storage capacity of 45,000,000 gallons and it is proposed to construct a second reservoir at a cost of £30,000 to hold 50,000,000 gallons.—The supply of water to Llanelli in Carmarthenshire, although not insufficient in quantity, has been recently reported upon by inspectors of the Local Government Board as very unsatisfactory in quality, and the district council is being urged by the board to take steps to provide for the efficient filtration of all water supplied for domestic purposes, and also to reduce as far as possible the sources of pollution in the gathering grounds. The water running into one reservoir is compared by the Board's inspectors to pea-soup, and they state that on the gathering ground there are 38 farms and 55 cottages, many of which drain into ditches and streams which eventually discharge into the reservoir and are gradually filling it up with solid matter.—In the Rhondda and Pontypridd districts, as already stated in THE LANCET of Sept. 21st, 1901, p. 817, the principal supply reaches the consumer so discoloured with peat that he refuses to drink it. In 1899 Professor Percy Frankland reported that this water was inefficiently filtered and quite recently examinations made in the Cardiff Public Health Laboratory show that no improvement has taken place in this respect. A clause in the Pontypridd Waterworks Company's Act provides that the water as it enters the mains shall not only be "pure and wholesome" but that it shall also be "properly filtered." There can, therefore, be no reason for not calling upon the company to carry out its statutory obligation.

*New Poor-law Infirmary at Bristol.*

The wooden huts at Eastville for the accommodation of the sick poor have long been a blot upon the Poor-law administration of Bristol. It is therefore very gratifying to be able to record that on Nov. 29th the board of guardians decided to advertise for tenders for the erection of a new infirmary, the cost of which, exclusive of the site and of furnishing, is estimated at £142,000, a sum which if borrowed and repayed in 30 years means an addition to the rates of the city of one and one-eighth of a penny in the pound. At present there is accommodation at the Stapleton Workhouse for 270 patients and at Eastville for 200, of whom 175 are in the huts. That this accommodation is totally inadequate is shown from the statement made by a member of the board that even now at the beginning of the winter there are 834 sick persons in the two workhouses.

*University College, Cardiff.*

The successor to the late Principal Viriamu Jones is Mr. Ernest Howard Griffiths, M.A., F.R.S., Fellow of Sidney Sussex College, Cambridge. Mr. Griffiths is the son of the late Rev. Henry Griffiths, a former principal of the Brecon Theological College.

*Censure upon Cardiff Workhouse Officials.*

An inquest was held in Cardiff on Nov. 28th and 29th upon

the body of an illegitimate child 19 months old, of rachitic constitution, who had died from pneumonia three days after removal from the workhouse, and who was found post mortem to have a fractured arm of several weeks' standing, an injury which, it is alleged, had not been recognised by the workhouse officials, although the child had been an inmate of the institution since the middle of August. As the coroner's jury expressed the opinion that certain officials deserved censure for their conduct in the matter the board of guardians has resolved to ask the Local Government Board to hold an inquiry into the circumstances of the case.

#### *Royal Albert Hospital, Devonport.*

The thirty-eighth annual meeting of the subscribers of this institution was held on Nov. 28th, under the presidency of Lord St. Levan. The report stated that during the past 12 months 509 in-patients were admitted, compared with 646 in the preceding year; in the casualty department 1484 patients were treated and there were 883 out-patients; 160 women were treated in the lock ward; 146 patients were sent to the Pearn Convalescent Home. The financial statement showed that the income amounted to £5267 and the expenditure to £5400, the gradually accumulating adverse balance being now £600.

Dec. 2nd.

### SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

#### *Glasgow Public Health.*

THE Local Government Board for Scotland has intimated to the city authorities that as no death from, or fresh case of, plague has taken place in Glasgow since Nov. 17th the Foreign Office has been informed that the port should now cease to be considered as infected with plague. In proposing the adoption of the minutes of the Health Committee at a recent meeting of the town council the convener drew attention to the fact that there were two cases of small-pox in the hospital. On the same occasion a block plan showing the proposed site of a new small-pox hospital was submitted and received a general approval, the details, however, being remitted for further consideration. The council has approved of a proposal to appoint a qualified assistant in the city bacteriological department for a term of six months, the nomination being in the hands of Dr. R. M. Buchanan and the chairman of the Health Committee. As part of the general scheme of public lectures in connexion with the several corporation departments a lecture on Bacteriology in Relation to Public Health was delivered in St. Andrews Hall on Nov. 30th by the city bacteriologist, Dr. R. M. Buchanan. Special attention was given to the spread of bubonic plague to the western hemisphere and to the influence of rats as agents conveying the infection. The lecture, which was freely illustrated, attracted a considerable audience.

#### *Glasgow Western Infirmary.*

The annual general meeting of contributors to the Glasgow Western Infirmary was held on Nov. 28th, the Hon. the Lord Provost in the chair. The report, which had previously been circulated, showed an increase of 479 in-patients and 1077 out-patients over the figures of the previous year. In the financial statement, though the ordinary income was nearly £1000 in advance of last year's record, there was a deficit of more than £8000 which had had to be met by drawing upon legacies and other sums that ought more properly to have been added to the funds invested for the benefit of this institution. The pressure upon the medical and surgical resources of the hospital continues, and there are at the present date nearly 300 patients waiting for admission. This fact, and the growing necessities of the hospital as the clinical school of the university and in some measure also of the extra-mural colleges are necessarily forcing into prominence the suggestion that the accommodation of the institution should be increased by the erection of a new wing. In the meantime the managers are asking for financial support to enable them to proceed with the new out-patient department. The scheme proposed in this direction is estimated to cost about £40,000, towards which upwards of £20,000 have been subscribed. The claims of this department are now so urgent that the managers feel compelled, in spite

of the appeals from other charitable and educational institutions, to urge their position on public attention. The Lord Provost moved the adoption of the report, and speeches in support were made by Mr. Parker Smith, M.P., and Principal Storr. The cost of the suggested new wing would be something like £25,000.

#### *St. Andrews University.*

The half-yearly meeting of the General Council of St. Andrews University was held on Nov. 29th, Principal Donaldson being in the chair. The council were occupied in discussing the University finances, the teaching of modern languages, and Mr. Carnegie's gift. It was announced that the ordinances founding the Bute Chair of Anatomy and the Chandos Chair of Physiology had been approved by His Majesty the King in Council. Full provision, therefore, now exists at St. Andrews for the first two years of the medical curriculum.—Professor Purdie has offered to the University the sum of £500 for the purpose of building and equipping a chemical research department in memory of the late Mr. Thomas Purdie of Castlecliff. It is a condition of the gift that the Carnegie trustees should regard the scheme with favour and be willing to assist in its promotion.

#### *Medico-Chirurgical Society of Aberdeen.*

At the recent annual meeting of this society the following office-bearers were elected for 1902:—President: Dr. D. W. Finlay. Vice-President: Dr. John Gordon. Secretary: Dr. John Marnoch. Recording Secretary: Dr. Ashley W. Mackintosh. Treasurer: Dr. W. Findlay. Librarian: Dr. Peter Howie. Members of Council: Dr. G. M. Edmond, Dr. Angus Fraser, Dr. D. W. Geddie, Dr. G. Watt, Dr. Albert Westland, and Dr. W. H. Williamson.

#### *University of Aberdeen Extension Fund.*

The subscription from the principal and professors of the University has been increased to £1200. Two gentlemen have offered £500 each on condition that 18 other subscriptions of same amount are obtained; and one gentleman is willing to increase his contribution by £50, making it £250, provided two subscriptions of £250 are counted as one of £500 in this connexion. Lord Provost Flemming, while in London, obtained subscriptions to the amount of £650. Several contributions of £100 and over have been recently intimated from the incorporated trades, and it is believed that the total donation from this source will amount to £1000, for which Principal Marshall Lang made an eloquent appeal at the convener dinner lately. At a meeting of the Students' Representative Council on Nov. 23rd a motion to the effect that the students as a whole should make a contribution towards the University extension scheme was defeated, the general feeling being that all students, whether able to give or not, would feel bound to subscribe. The total amount now promised (exclusive of conditional subscriptions) is slightly in excess of £14,500. This sum includes one subscription of £700 "In memory of Professor Jas. Kidd, D.D." and one of £300 from Sir Thomas Sutherland, London.

#### *Freedom of the City of Aberdeen for the Lord Rector.*

Lord Strathcona hopes to be able to come north early in the New Year, when he is to receive the freedom of the city of Aberdeen in consequence of his generous offer of £25,000 to the University Extension Fund.

#### *Senatus of Aberdeen University.*

On Nov. 30th a meeting was held at King's College. Professor J. W. H. Trail was re-elected assessor for a further term of five years. An acknowledgment was received from the president and fellows of Yale University, U.S.A., of the address of congratulation sent by Aberdeen University through its representative, Professor David Finlay, in connexion with the two-hundredth anniversary of the founding of Yale College. Professor Finlay, on whom the honorary degree of LL.D. of Yale University was conferred, also handed to the principal for custody a handsome commemorative bronze medal struck in honour of the celebration.

Dr. Ebenezer Duncan of Crosshill, Glasgow, has been appointed a justice of the peace for Renfrewshire.

Professor John Young, M.D. Univ. Edin., has been re-elected chairman of the Kelvin-side Ward Committee, Glasgow.

Dr. Philip C. Walker, who has for 12 months been resident

medical officer at the Paisley Fever Hospital, has sailed for South Africa, where he is to undertake duties in connexion with one of the concentration camps.

Dr. David Yellowlees has been appointed president of the Glasgow Medical Missionary Society.

Dec. 3rd.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

### *Fees of Medical Witnesses in Ireland.*

A DECISION of much importance and interest to the medical profession in Ireland with reference to the statutory fees of medical witnesses was pronounced in the Court of King's Bench on Nov. 25th, being contained in the judgment of Mr. Justice Kenny—with whom Mr. Justice Barton and Mr. Justice Wright concurred. In January last an action for damages against the Great Northern Railway Company of Ireland was tried before a judge and special jury in Dublin, resulting in a verdict for the plaintiff, by which he was awarded £450. Subsequently the costs were taxed and the railway company objected to certain allowances made by the taxing-master, more especially those to the medical witnesses. They objected to those charges, relying upon the schedule of costs by which, they submitted, the master was bound. That schedule provided that for professional witnesses residing within five miles of Dublin only one guinea a day should be allowed for attendance in court, unless in the opinion of the taxing-master the case was an exceptional one. The company submitted that in the present case there was nothing exceptional to justify an increase in the scale allowances. Mr. Justice Kenny, in delivering judgment, said, in reference to the payment of the medical witnesses, that the court considered that they were bound by the schedule and the decision of the Master of the Rolls in *Machonchly v. The Bank of New Zealand*, and that under the schedule they could not allow for attendance of medical witnesses in court more than one guinea a day to medical men resident within five miles of Dublin and three guineas to medical men outside that limit. They were, moreover, unable to see any exceptional circumstances in this case that would justify the taxing-master in allowing more than one guinea a day to the Dublin medical men. Mr. Justice Barton, in concurring, said that the court considered that the scale was binding on the master even in the case of medical men of exceptional eminence (the President of the Royal College of Surgeons in Ireland was a witness in this case). Mr. Justice Barton added that in England the taxing-master had a discretionary power in these matters, while in Ireland the rule was binding. Mr. Justice Wright also concurred, and said that the matter was of great importance to the plaintiff in this case, and of immense importance to railway companies who had constantly to face claims which were in the nature of sham actions. Both of the judges agreed with Mr. Justice Kenny, who had stated that he would not be dissatisfied if the case was taken to the Court of Appeal. Apart from the above case, and quite outside of it, it is notorious in Dublin that some medical men who are frequently called upon as expert witnesses in actions for damages, for and against railway and other companies, have occasionally appeared rather to resemble advocates for those for whom they were asked to give evidence, hence the remarks of Mr. Justice Wright which I append from the *Irish Times* of Nov. 26th. Mr. Justice Wright said: "He should be glad if the Court of Appeal would lay down some decision for their guidance which they would loyally follow. The taxing-master said the medical gentlemen had remained a long time in court. Sometimes medical men thought they were engaged in a duel. They remained in court listening to the evidence for the claimant with the view—well, of disproving what had been said on the other side. One of the dangers arising from that was that they were apt to forget their character of witnesses to tell the truth and become advocates of the side employing them. He did not say that their decision would reduce that tendency, but certainly it would not encourage the doctors to remain in court." The matter cannot well rest here. The decision may be reversed by the Court of Appeal, otherwise medical

men of position in Dublin will no longer appear as witnesses until after their suitable fees are personally guaranteed by those who request them to give evidence. That would seem regrettable for many and obvious reasons. On the other hand, it is unreasonable that a medical man should be asked to appear and to await the convenience of a court for hours, dissolve his engagements for the day, and undergo a cross-examination which may or may not be controlled by the presiding judge. (It may prove an unpleasant ordeal if the licence sometimes given to adverse counsel in the examination of all witnesses chances to prevail). It is preposterous to suppose that any medical man of high reputation in Dublin would accept voluntarily the position and give evidence in court under those conditions for a fee of one guinea per day. They will certainly refuse to do so, and the superior courts of law must accordingly be satisfied in future with the medical evidence of inferior members of the medical profession, or have the present condition of the law—as disclosed by the above-mentioned judgments—amended.

### *Health of Belfast.*

I am glad to say that there is a marked decrease in the number of cases of typhoid fever in the city, these being lower than at the corresponding period of last year. For the period between Oct. 20th and Nov. 16th (report presented to the city council on Dec. 1st) 200 cases of typhoid fever have been notified. In the Woodvale and Shankhill districts, where the disease has been specially prevalent, it seems to be dying out. The death-rate from zymotic diseases is considerably lower than it was last month, while, owing to the season, that from chest ailments shows an increase. Dr. A. G. Robb has been appointed to inspect the catchment area of the water-supply. The annual death-rate from all causes for the four weeks up to Nov. 16th was 18·5 per 1000, that for children under one year old was 3·2, and that for persons aged 60 years and upwards was 3·7 per 1000 of the population.

### *The Rainfall in November.*

There were 12 days' rain in Belfast during the past month, amounting to 4·64 inches. Nov. 11th and 12th were the wettest days, when over three inches of rain fell.

### *Larne Water-supply.*

The Larne Urban District Council have wisely decided to apply to the Local Government Board for their sanction to a loan of £4700, repayable in 35 years, in order to enlarge their reservoir and to make new water-mains. This scheme, if carried through, will be of the greatest service to the town and will do away with the inconvenience caused in the past. It is of the utmost importance that Larne—a sea-side resort on Belfast Lough much frequented by the citizens of Belfast—should have an adequate water-supply.

### *Appeal on behalf of the Late Mr. W. Smyth, I.R.C.S. Irel.*

IN THE LANCET of last week (p. 1539) attention was drawn to the heroic death of an Irish dispensary medical officer, Mr. W. Smyth, which took place at his residence, Burton Port, Donegal, the cause being typhus fever, contracted in bringing over from Arranmore Island some fever-stricken patients to the mainland for proper hospital treatment. An appeal on behalf of his widow and eight children, signed by Dr. W. Calwell, 1, College-square, N., Belfast (secretary of the North of Ireland Branch of the British Medical Association), Mr. Robert Campbell (secretary of the Ulster Medical Society), and Mr. Henry Woods, The Bank Buildings, Belfast (treasurer), has been sent out to the members of the medical profession and others in Belfast and district who may wish to join in a local movement to show their appreciation of an act which sheds lustre on the medical profession the world over. The following subscriptions are already promised:—

£ s. d.		£ s. d.	
Sir James Musgrave,		Professor W. Whitla	2 2 0
Bart., D.L.	5 0 0	Mr. John Wales, J.P.	1 1 0
Mr. W. Robertson, J.P.	5 0 0	Sir James Henderson,	
Mr. Henry S. Woods	5 0 0	D.L.	1 0
Professor J. W. Byers	2 2 0	Dr. S. Darling	1 1
Dr. W. Calwell	2 2 0	Dr. G. Bracken	1 1 0
Professor Lindsay,	2 2 0	Mr. John Y. Calwell	1 0 0
Dec. 3rd.			

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

*Politics and Foundlings.*

A HEATED discussion which has just taken place in the General Council of the Department of the Seine has once again shown how political considerations affect questions of Poor-law administration and charity organisation. This time the matter in hand was the case of children abandoned by their parents to the care of the State, such children, that is to say, as were formerly called "*enfants trouvés*," from being left in the street. These children are cared for by the Assistance Publique in a special hospital at Paris during their infancy and later they are distributed throughout the country among various peasants who are charged to bring them up with their own families and to teach them a trade. The Assistance Publique pays a small subsidy for their keep and supplies medical inspectors whose duty it is to visit the baby-farmer and to see that the children are being properly cared for. The parents of the children know nothing as to where the children may be, but are allowed to attend once a year at the chief office of the Assistance Publique to hear the latest news of them and whether they are alive and well. On a child reaching the age of 16 years the parents can reclaim him or her provided that they pay over to the Assistance Publique a sum of 1500 francs which in part repays the cost of the child's bringing up. This sum, too, represents a little subsidy both for the baby-farmer and for the medical inspector and, as a rule, it is thought a good deal of. It is quite certain that the choice of a baby-farmer is regulated by political considerations, and the same thing practically paralyses the action of the medical inspector, as, for instance, in a case where he should exercise his official powers and order a child to be taken away from one baby-farmer and handed over to another because it is not properly looked after. Many country practitioners are deeply involved in politics, either because they canvass their patients to elect them as municipal councillors or deputies or else because they act as election agents for other politicians with a view to getting a well-paid appointment or a decoration as a reward. Gross scandals have arisen from causes such as these. For instance, only the other day neither the mayor of the commune nor the medical man had the courage to denounce a baby-farmer, in the charge of whom four children had died one after the other, because his position as a prominent elector and a *protégé* of the deputy rendered him unsailable. After a heated debate various motions were put forward, some suggesting that medical inspectors should have nothing to do with politics either on their own behalf or on that of anyone else, others that they should be incapable of holding any official position, others again that they should not be local men, as such were hindered in their work by personal relations, but should be sent from Paris after being chosen by public competition among recently qualified practitioners. The committee of the Assistance Publique argued in defence that the facts put forward were much exaggerated and pointed out the various undeniable improvements which have recently been introduced—as, for example, the observation hospital at Chatillon for children suspected to be suffering from tuberculosis. Again, many of the medical inspectors are appointed for life and cannot be replaced until they resign or die. The committee, however, did not seem unwilling that in the future the posts becoming vacant should be filled up from Paris in the manner indicated above.

*The Consumption of Alcohol since the New Licensing Laws.*

When the new regulations as to alcoholic drinks came into force there were not wanting those who expressed the opinion that they would increase the consumption of wine without diminishing that of spirits. It is quite certain that the consumption of wine has gone up, probably by 20 or 25 per cent., but it is much to be feared that the consumption of spirits has not diminished. The removal of the *octroi* duties this year happens to have coincided with a plentiful wine crop and consequently with very low prices. In fact, the price of wine has dropped quite 50 per cent. The average workman, however, does not economise by this, for instead of drinking

half a litre of wine with his dinner he drinks a litre, and probably when prices rise he will not limit his consumption accordingly. Cases of cirrhosis are not on the decrease. The Ministers of Agriculture and of Finance have been inquiring into the subjects of viticulture and the consumption of wines as affected by the recent reduction in the taxation of wholesome drinks. The figures obtained show that during the first four months of 1901 the amount of wine consumed amounted to 18,000,000 hectolitres as against 10,000,000 hectolitres for the corresponding period of the year 1900. This is nearly an increase of 50 per cent. It was also stated that there appears to be a manifest tendency to drink white wine in place of absinthe. For Paris, however, this statement does not seem to rest on any good foundation.

Dec. 3rd.

## ROME.

(FROM OUR OWN CORRESPONDENT.)

*The Admission of Foreign Graduates to Italian Degrees in Medicine.*

In a recent letter<sup>1</sup> I referred to the possibility of a change being made in the law which permits of the admission on very easy terms of graduates of foreign universities to Italian degrees in medicine. Action in this direction has already been taken by the Ordini dei Medici who at their annual meeting held in Rome on Nov. 9th to 11th passed a resolution calling for the abolition of a system which they hold to be detrimental to the interests of Italian medical men and demanding that no one shall be allowed to take the *laurea* of an Italian university unless he has passed all the examinations and taken out all the courses of lectures obligatory on its own students. Although the professed and immediate object of this proposal is to equalise matters with foreign universities which do not offer any return for Italian liberality, the real end in view is to protect the native practitioner from foreign competition. In this respect it doubtless indicates a determination to close up all side avenues by which the foreign practitioner might possibly re-enter the field when the long-threatened law cancelling his present privileges and thus excluding him from it shall have finally been passed. Meanwhile the agitation in favour of this law appears to have been dropped, its promoters probably realising that under its pressure the majority of the foreign medical men, now content with their practice amongst foreigners, would be driven to take Italian degrees and thus become more dangerous rivals than before. As long as the present facilities exist for obtaining such degrees this will be the natural effect, hence the anxiety that first of all these facilities should be immediately abolished.

*Pellagra in Italy.*

A comparison of the numbers of *pellagrosi* as they appear from the census tables of 1881 with those of 1899 reveals, according to Professor Pagliani of Turin a diminution of pellagra in recent years in northern Italy and especially in Lombardy, the Veneto, and Emilia. Among every 1000 of the agricultural population of these provinces the quota of affected persons has fallen during the period mentioned from 27.36 to 12.90, from 53.67 to 34.32, and from 7.79 to 4.27 respectively. It is in these same districts that philanthropic effort has been most active in providing for the pellagrous hospitals, sanitary dwellings, soup kitchens, arrangements for the proper drying of maize, &c. It is, on the contrary, disquieting to find in other provinces where a few years back pellagra was very mild and uncommon or altogether unknown that a sensible augmentation, and in many cases a great increase, has taken place. For instance, in Piedmont, although the actual number of cases remains about the same, there are a good many more *lunatic pellagrosi*. In the Marches, Umbria, and Tuscany the number of cases has quadrupled, passing in the first two districts from 2 to 8.82 and in the last from 0.10 to 0.40 per 1000. Deaths occurred from pellagra during 1899 in the Abruzzi, in Campania, and in Puglia. The supposition that this increase is due to an accentuation of the impoverished condition of the people is in contradiction to the fact that the general mortality there, as elsewhere in

<sup>1</sup> THE LANCET, Oct. 26th, 1901, p. 1163.

Italy, has diminished in the last decade: moreover, poverty is known to be only a predisposing, and not an efficient, cause of pellagra. Nor can it be ascribed to an extension of the cultivation of maize and consequent increase in the use of that grain as food. On the other hand, the evidence is strong that the spread of infection is in close relation to the importation of damaged maize from America, an importation which has increased at an extraordinary rate in the last few years. Since about the year 1895 it appears that speculators have been buying up maize on the coasts of the Argentine Republic and United States and transporting it at a trifling cost to Italy, where it is sold in immense quantities and at an enormous profit. During its passage across the ocean through warm latitudes this maize, newly reaped, immature, and imperfectly dried, becomes mouldy in the vessel's hold and so acquires those poisonous properties which have now been proved almost certainly to be the cause of pellagra. Although there has been an ordinance on the Statute book since 1895 prohibiting the importation into the kingdom of damaged maize for any purpose whatever concessions made to the speculators by the Government have neutralised its effect and the poisoned grain has been finding its way to many parts of Italy with results disastrous to the public health, increasing the numbers of *pellagrosi* in the affected districts, and originating fresh cases where none had previously existed. The Minister of the Interior has now issued stringent orders to the prefects instructing them to see that in future the existing regulations are applied with the utmost rigour.

## NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

### *The Health of the Army.*

SURGEON-GENERAL STERNBERG has submitted his annual report to the Secretary of War, from which it appears that the admission-rate to hospitals for all causes in the army, volunteers and regulars, with a mean strength of 190,389 in 1900, was 2311.81 per 1000 of strength, as compared with 2187.06 in the previous year; but in the year 1899 only 39,280 men out of a total of 105,546 were serving in the Philippines, while in the last year 68,882 out of a total of 100,389 were thus serving. In the Philippine Islands, with a mean strength of 66,882, the admission-rate was 2621.96, as compared with 2395.52 in the previous year, this increase being mainly due to diseases among the volunteers, the ratio for which rose from 1859.21 to 2761.79. The regulars, on the other hand, showed a marked decrease in the ratio of admissions for disease, which fell from 2454.10 to 2197.73. Two-thirds of the admissions for disease were caused by malarial fevers and diarrhoeal diseases. The deaths from all causes amounted to 28.75 per 1000 of strength, as compared with 30.58 in the previous year. Disease occasioned 20.26 deaths, the principal cause of the fatalities being dysentery, which with other intestinal diseases gave a ratio of 9.08. The rate from injury amounted to 8.49. The death-rate in China was large, 47.76 per 1000 of strength, 23.62 from diseases and 24.14 from injury. From the close of the calendar year 1900 to the latest reports the health of the troops in the Philippines has been steadily improving. The health of the troops in Cuba during the year was excellent. As a result of American occupation nearly every city and town has had its sanitary condition improved. There has been a steady decrease in the past few years in the number of admissions for alcoholism among the men of the regular army. Military officers may be said to be unanimous in their opinion that this is the result in the main of the establishment of the post exchange or canteen at military posts. There is less drunkenness among troops in active service than in a command doing garrison duty in times of peace.

### *Results of the Study of Yellow Fever in Cuba.*

Surgeon-General Sternberg, our best authority on the causation of yellow fever, gives the following opinion of the studies recently carried on in Cuba. The results obtained were especially valuable, showing that the bacillus *icteroides* (Sanarelli) bears no causative relation to yellow fever and that the mosquito serves as an intermediate host for the

parasite of this disease. Further experiments of a most interesting character demonstrated that yellow fever is transmitted to non-immunes by the bite of a mosquito that has previously fed on the blood of those suffering from the disease; that yellow fever can be produced by the subcutaneous injection of blood taken from the general circulation during the first and second days of the disease; that an attack of yellow fever produced by the bite of a mosquito confers immunity from the subsequent injection of infected blood; that yellow fever is not conveyed by clothing, bedding, or merchandise soiled by contact with those who are suffering from the disease; and that the spread of this disease can be most effectually controlled by measures directed to the destruction of mosquitoes and the protection of the sick against the bites of these insects. The results of this investigation are of far-reaching importance, as the surgeons are now in possession of knowledge which enables them to stamp out yellow fever.

### *Tetanus following the Use of Diphtheria Antitoxin.*

Answering a request for information regarding deaths from antitoxin in St. Louis Dr. MacC. Starkloff, the Health Commissioner of that city, reports the occurrence of 20 cases of tetanus following the use of serum and ten deaths. The horse from which the antitoxic serum was taken was originally an ambulance horse, but having met with an accident to its shoulder had been under treatment for the production of diphtheria antitoxin for nearly three years. The animal had been bled a number of times and had furnished over 30,000 cubic centimetres (30 quarts) of diphtheritic antitoxin. As a matter of fact, the Health Department secured the greater part of the antitoxin distributed during the years 1900 and 1901 from this horse, which seemed to be in perfect physical condition when bled on August 24th and Sept. 30th. The bleeding on the latter day was followed by a decided reaction, and on the following day the horse refused food and experienced difficulty in breathing. The veterinary surgeon pronounced the animal sick beyond recovery from tetanus and it was killed. The city bacteriologist states that he is confident that the tetanus bacillus will not be found in the serum, basing his opinion from the painstaking care with which it was prepared, and from the fact that it contained 0.04 per cent. of tricresol. It is, however, within the limit of probability that the horse may have had the tetanus bacillus latent for some time before August 24th, and that the disease did not develop sufficiently to manifest itself until vitality was lowered by the bleeding of Sept. 30th. If this were so the tetanus toxin might have been in the blood on August 24th, the date of the bleeding. If the tetanus toxins were in the horse's blood prior to August 24th it was beyond the range of human knowledge to detect it by an inspection of the animal. It is a well-known fact that horses undergoing treatment for the production of diphtheria antitoxin are highly susceptible to the infection with the bacillus of tetanus. The department has lost six antitoxin horses from tetanus since 1895.

### *Sanitation of North and South American Ports.*

Surgeon-General Wyman of the United States Marine Hospital Service intends to bring forward at the International Conference of American States shortly to be held in Mexico a scheme for the sanitation on uniform lines of all North and South American ports. Surgeon-General Wyman's plan provides for the appointment of an International Sanitary Commission to consist of five members, two of whom shall be residents or citizens of the same Republic. Law, sanitary science, medicine, and commerce are all to be represented. South America will be asked to prevent the spread of infectious diseases by an international agreement in which the health authorities of the respective countries and States of both continents will participate. Harbours, sewerage, and drainage, as well as the warding off of infection from buildings, will be the points considered. Preventive measures against the spread of yellow fever will be a special object of this commission. The recent investigations in Cuba and the experience taught to Americans during the Spanish-American war will doubtless prove of peculiar value in this connexion. The whole plan is a step in the right direction.

Nov. 15th.

**NEW INFIRMARY AT SWANSEA.**—The Swansea Board of Guardians are about to erect a new infirmary for the workhouse and on Nov. 27th a tender of £15,681 for the execution of the work was accepted.

## Obituary.

SIR WILLIAM MACCORMAC, BART., K.C.B., K.C.V.O.,  
F.R.C.S. ENG. AND IREL., D.Sc., M.CH. R.U.I.,

HONORARY SERGEANT-SURGEON TO H.M. THE KING; CONSULTING  
SURGEON TO, AND EMERITUS LECTURER IN SURGERY AT,  
ST. THOMAS'S HOSPITAL; LATE PRESIDENT OF THE  
ROYAL COLLEGE OF SURGEONS OF ENGLAND, ETC.

THE medical profession will have heard with deep regret of the sudden death of Sir William MacCormac, which took place at Bath on Wednesday morning last.

Sir William MacCormac was born at Belfast on Jan. 17th, 1836, his father, Dr. Henry MacCormac, being a medical practitioner in that town. Dr. Henry MacCormac was a distinguished man, a linguist, an expert in tropical diseases, and a pioneer of the open-air treatment of phthisis; he was in every way the sort of man from whom a successful son might be expected. Sir William MacCormac's mother was descended from the Newsam family, respected merchants of Belfast.

Sir William MacCormac received his education at the Belfast Institute, where, in his earliest days, he made use of the powers of observation which in later years stood him in such good stead. At this institution his father held a professorship for some years. After a few years young MacCormac proceeded to Dublin, going thence to complete his studies in Paris. He graduated at the Queen's University of Ireland in 1856 as a Bachelor of Arts, and two years later proceeded to his Master's degree. During his college days he showed himself an athlete of some note, and by his geniality and diligence gained very many friends both among his teachers and fellow students. It was not until he had graduated in arts in 1856 that he turned his attention finally to the study of medicine. He had long felt a leaning towards the profession of his father, from whose ample and diversified store he had already picked up many crumbs of knowledge. After an unusually active and brilliant career as a student he qualified at the Queen's University of Ireland, and in 1864 became a Fellow of the Royal College of Surgeons in Ireland. In the same year he was elected surgeon to the Royal Belfast Hospital, and during his six years' tenure of that post he did much excellent work. It was in great measure to experience gained in this splendid institution that he owed the unflinching accuracy that characterised his work as a military surgeon. While at Belfast he made injuries of joints his especial subject, not, however, by any means neglecting a wider view of clinical surgery as a whole. His ward teaching was from the beginning of his career as a staff surgeon of high order, as very many of his old pupils and colleagues now practising in England and Ireland can gratefully testify.

MacCormac's connexion with the Queen's University of Ireland was very intimate, and from that body he received the honorary degrees of Master of Surgery in 1879 and Doctor of Science in 1882, as well as its gold medal; while for many years he was a member of its Senate and an Examiner in Surgery. He did a large share of the work which resulted in the recognition of the Queen's University among the teaching institutions in the sister island, applying his best energies to his duties as a member of the Senate and doing valuable work both as a surgeon and a surgical teacher.

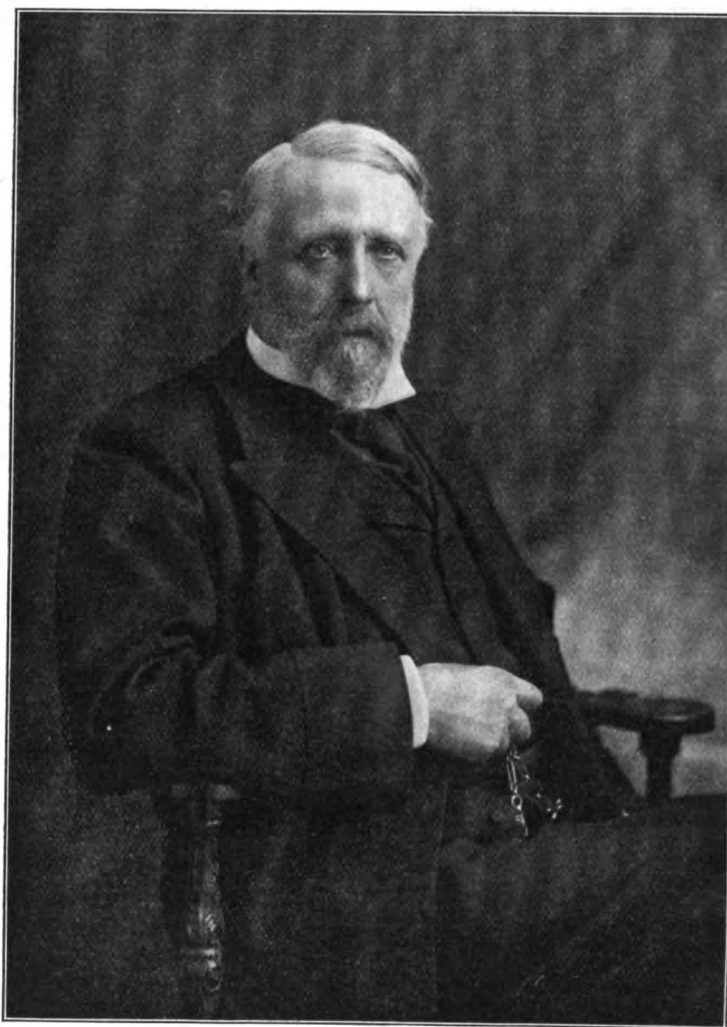

In the year 1870 the Franco-Prussian War was the paramount topic of the day: the newspapers teemed with details of the campaign, and the chief matters of discussion were the doings of the two armies and the characteristics of their several generals. The medical arrangements were, on the French side especially, totally inadequate to provide for the due care of the poor victims of the chassepot and the needle-gun; the hurry which characterised all the movements of the French authorities during this disastrous campaign was even more noticeable in the ambulance arrangements than in the commissariat and munitions departments—and, as history shows, these were bad enough. It was not only the desire "to see what military surgery was like," to use his own expression, but a feeling of deep humanity which led MacCormac to throw up his appointment at Belfast and make for

Paris to volunteer his services for the aid of the wounded French soldiers on the German frontier. After a good deal of discouragement from the French authorities, who were exceptionally severe in their exclusion of foreigners, for the spy panic was at its height, MacCormac was, chiefly through the instrumentality of Nélaton, permitted to proceed to Metz and instructed there to report himself to M. Isnard, the surgeon-in-chief. This was, it will be remembered, the period at which Maréchal Bazaine was with his *corps d'armée* awaiting the Prussian attack before the fortress of Metz. The English surgeon was welcomed by the medical staff, but by the military authorities, still on the almost insanely ardent search for spies, he was requested to leave Metz and to retire to Chalons. During his short stay he had nevertheless seen a good deal of the practice in the Metz hospitals and was thus prepared for what he was to see anon. After some further trouble with the authorities MacCormac succeeded in joining the Anglo-American Ambulance, a body consisting of 16 medical men, of whom eight were English and eight American, and over whom Dr. Marion Sims presided. On the reconstruction of this body MacCormac was placed second in command, which position he shortly afterwards, on the return of Dr. Marion Sims to New York, changed for that of Surgeon-in-Chief. Within a few days of his joining this noble mission MacCormac and his companions were in the thick of the fray. Each day considerably more than a hundred major operations were performed and MacCormac's share of these was more than would have fallen to him by lot. A day of his work at Caserne d'Asfeld cannot be better described than in his own words, "I did not succeed in keeping a record of all the work that was done that day. Indeed I only wonder I kept any record at all. I find, however, that I performed several amputations of the leg, the thigh, the forearm, and the arm, that I excised the shoulder and the elbow-joints and also performed partial resections of the upper and lower maxillæ and of nearly the whole ulna. The number of bullets and pieces of shell that were extracted from various parts of the body are too numerous to reckon." This record of a day's operative surgery is sufficiently startling, but MacCormac did very many such days' work before the war on the frontier practically terminated. His operations were successful as a whole, and when we call to mind the terribly insanitary buildings which had to be utilised as hospital wards and the imperfect assistance with which the surgeons had to be content his results were surprisingly satisfactory. He did not himself escape entirely free from the effects of his arduous work, for on the fifth day of his service he writes in his diary:—

"To-day I was annoyed to find that a cut I had received on the finger had become poisoned, and that the lymphatics up the arm were inflamed. I had a smart rigor and felt very unwell for a day or two, but then I got quit of it, and although I afterwards repeatedly jagged myself with needles and had several cuts on my fingers which were constantly being dabbled in the offensive discharges from wounds, it seemed, strange to say, as if the first inoculation had procured for me future immunity, for I experienced no further trouble from that cause whatever, although the hospital was for a long time in a very poisonous state."

It must truly have called into play all MacCormac's physical endurance and determination to continue work under such conditions. But he was, above all, a man who could never conceive the possibility of turning back from any task to which he had once set himself. The only fault it would be possible for even the most critical observer to find with his work in war surgery in this campaign is that he was, as many civil surgeons would have been, somewhat too anxious to avoid amputation and to save the limb; in pursuance of this intention his results were numerically not so good as his skill warranted. Bullet injuries following the weapons used in the Franco-German war were awkward as to after-treatment, and the attempted saving of the limb sometimes jeopardised life.

On his return to England MacCormac was elected assistant surgeon to St. Thomas's Hospital in recognition of the unique surgical experiences through which he had just passed. With the affairs of this institution he maintained the closest connexion until the day of his death, being successively assistant surgeon, surgeon, lecturer in surgery, consulting surgeon, and emeritus lecturer in clinical surgery. His work at St. Thomas's Hospital will be gratefully remembered by a large number of our readers who have had the privilege of his personal guidance in

*William Mac Cormac*

their studies and have watched his skilful practical demonstrations. William MacCormac was eminently adapted to capture the confidence and liking of those students and practitioners, especially the younger men amongst them, who came under his immediate influence. There was a steadiness about all he did, an absorption in the immediate action, which could not but inspire the young men with whom he had to deal with the feeling that he was one who had encountered and triumphed over difficulties. The gift, also, of seeing the pitfalls into which students might most easily fall was not the least among the qualifications he possessed as a successful and popular teacher.

In 1871, the year that he was elected to fill the post of assistant surgeon to St. Thomas's Hospital, he became a Fellow by examination of the Royal College of Surgeons of England and in 1883 was elected a Member of the Council of that body. His connexion with the College from henceforth was very close. In 1887 he was appointed a member of the Court of Examiners, of which he was eventually chairman, and in July, 1896, he was elected to the presidential chair in succession to Mr. Christopher Heath. As an examiner Sir William MacCormac's qualities came into full play, his clear style of expressing himself and his sympathetic method of putting questions to students who were hardly at their ease rendered him particularly popular. His questions were always searching, pertinent, and, above all, practical, and his method of putting them was reassuring. He had a real power of making candidates appear at their best. He was examiner in surgery to the University of London for many years, and also examined in surgery for a long period the candidates for commissions in the Army Medical Service, the Royal Navy Medical Service, and the Indian Medical Service.

Sir William MacCormac was re-elected President of the Royal College of Surgeons of England four years in succession, thereby holding the office for the unprecedented period of five years. Throughout this long tenure Sir William applied himself most assiduously to every detail of the manifold duties of the presidency, not only as regards the internal affairs of the College, but also as regards its external relations with the public and the State. He conducted the business of the College quietly but strenuously, courteously but firmly. As the representative of the College before the public he gained the respect and confidence of all ranks of society by his genial manner, his quick and active sympathy with everything that concerned the public health, and more particularly the welfare of our soldiers and sailors. The remarkable success of the celebration of the centenary of the College last year, with its many brilliant and imposing ceremonies, was in a very large degree due to his personal interest and influence. Chiefly through his initiative and instrumentality the (then) Prince of Wales, the Prime Minister of England, and the Earl of Rosebery, and a large number of the most eminent representatives of surgery throughout the world, were present to do honour to the College and to receive at the President's hands the distinction of the Honorary Fellowship of the College.

In 1881, when the International Medical Congress met in London, MacCormac was appointed secretary-general, and a more useful man for a difficult position could not have been found. He showed himself indefatigable in his endeavours to make the great gathering run smoothly, and won enthusiastic appreciation from the numerous foreign guests. His report of the transactions of this great meeting was an excellent compilation, and was translated both into French and German. The labour of this production alone was considerable, and at the end of the year in which the Congress took place MacCormac, to whom we have already alluded under his title, received the honour of knighthood.

When the war between the Turks and the Servians broke out and Eastern Europe was embroiled in the long strife which terminated so disastrously for the Turks at the hands of Russia, MacCormac was appointed by the Stafford House Committee surgeon-in-chief and played the principal part in disposing of the medical officers of the committee and the stores in the most efficient manner for the benefit and relief of the wounded. The good work done by the ambulance corps in this campaign was both welcome and successful. The inclemency of the weather and the wretched accommodation for the wounded, no less than the insanitary habits of the East, rendered such help almost indispensable, and the efficiency of the Stafford House

expedition owed much, indeed, to the experience and activity of MacCormac.

Then came more than 20 years of fruitful surgical work at St. Thomas's Hospital, during which time a large consulting practice was steadily built up. Our columns contain many accounts of interesting cases proving his dexterity and resource. In particular reference may be made to certain cases of operation for ruptured bladder, which will be found in THE LANCET, vol. ii., 1886, p. 1118. Here he describes the procedure which he undertook in two cases of intra-peritoneal rupture of the viscus. He performed abdominal section, washed out the peritoneal cavity, and sewed up the bladder, being a pioneer in this bold treatment. In 1897, in recognition of his position as President of the Royal College of Surgeons of England, he was made a baronet, while in July, 1898, came a still more direct acknowledgment of his high place in the surgical world. In this month he was summoned to attend the King, then Prince of Wales, who it will be remembered fractured his patella while descending a staircase at Waddesdon. Sir William MacCormac directed the treatment which resulted in a satisfactory union, and as a reward for his responsible services to the heir to the Crown was made a Knight Commander of the Victorian Order.

In the next year the routine of his official and professional work was rudely broken into, and for the third time in his life he started for the seat of a bloody war to place his services at the disposal of the wounded. Soon after the outbreak of the South African war the Government determined to avail itself of the services of three civilian consultants and in November, 1899, Sir William MacCormac left England for Cape Town, being shortly followed by Mr. G. H. Makins and Mr. (now Sir Frederick) Treves. On arriving at the Cape Sir William MacCormac lost no time in setting to work, beginning his experience of the campaign by visiting the General Hospital at Wynberg. From Cape Town he proceeded to Durban, thence to Pietermaritzburg and Frere. He assisted in the care of the wounded after Colenso, and then, returning to Cape Town, accompanied Lord Roberts to the Modder river and went on to Jacobsdaal and Kimberley. He served four months as civilian consulting surgeon, returning to England at the beginning of May, 1900. His experiences during the war were admirably set forth in the interesting series of letters which he wrote for our columns. Chosen by the Government to come to their aid because of his unique familiarity with the surgery of war, he modestly admitted in his account of what he saw during the campaign against the Boers that his past experiences did not avail him much. The surgery of gunshot wounds had, he found, been completely revolutionised by the introduction of modern arms, and he was himself in many respects a student. But his sound knowledge of surgical principles, as well as his enthusiasm for his science, enabled him to grasp quickly the new indications for treatment and the new modifications that must be made in diagnosis, so that it is easy to see that from the first he was able to render most valuable assistance to the forces. A sharp attack of dysentery temporarily invalidated him during his stay in South Africa, but he returned in good health. For his patriotic service to his country he was made a Knight Commander of the Bath at the beginning of this year.

Sir William MacCormac's works are not very many in number but some have been widely read. The most notable of them, perhaps, is "Work under the Red Cross," which consists of a series of graphic entries in his diary during the Franco-Prussian war illustrated by heliotypes. This work, from which we have already made one or two quotations, is marked by an unstudied directness which cannot fail to appeal to the general reader, although the wealth of surgical detail shows that the unpretentious volume was intended simply for medical men who, like MacCormac himself, felt an interest in seeing "what war surgery is like." The book has been translated by M. Morache into the French tongue and has enjoyed a wide popularity on the continent as well as in England. On Dec. 3rd, 1879, MacCormac opened a debate at a meeting of the Metropolitan Counties (South London District) Branch of the British Medical Association on the subject of Antiseptic Surgery. His paper was based upon a system of statistics and he dwelt chiefly on the application of Listerism to military surgery. The address was followed by a spirited debate in which Professor (now Lord) Lister, the late Sir Spencer Wells, Mr. Bryant, Mr. Macnamara, Mr. Barwell, Mr. (now Sir) Thomas Smith, and Mr. Timothy Holmes took part. The

debate was then adjourned and on meeting again on Dec. 17th Mr. Jonathan Hutchinson, Sir James Paget, Mr. Lund, Mr. Knowsley Thornton, and the late Mr. Morratt Baker spoke at some length. The valuable opinions thus adduced, together with a general chapter on the antiseptic theory, were published in volume form by Sir William MacCormac in the following year. This book forms a most interesting record of the period when Listerism was not entirely accepted by all, and when, although it had up to that time withstood all attacks, it was still looked on with a vague and hardly acknowledged suspicion by many of the old school of surgeons. The discussion which then took place may well be reckoned among the most useful debates that has ever taken place in the history of surgery.

In 1885 the first section of Sir William MacCormac's "Surgical Operations" appeared. It dealt with "The Ligature of the Arteries," and commenced with an account of the different modes of ligature, the conditions for which the operation is required, the details of its performance, and the effects which may result. After this each region was minutely dealt with, the whole being illustrated with beauty as well as accuracy. Sir William MacCormac did not confine himself to the bare details of surgical anatomy but at intervals digressed into clinical details. Although this part of the work met with deserved success and was re-published five years later, the remaining sections were never produced.

Sir William MacCormac remained up to the time of his death on the consulting staffs of the Royal Belfast Hospital, St. Thomas's Hospital, the French Hospital in Soho, the Italian Hospital in Bloomsbury, and Queen Charlotte's Lying-in Hospital. His services, besides receiving recognition at the hands of his Sovereign, were rewarded by a very large number of foreign honours, among them the Legion of Honour, the Order of the Dannebrog, the Order of the Crown of Prussia, the Order of the Crown of Italy, the North Star of Sweden, the Order of Saint Jago of Portugal, the Order of Merit of Spain, and the Order of the Takovo of Servia. He was likewise honoured by the Order of Ritterkreuz of Bavaria and the Medjedieh. His professional honours were, as has appeared in the course of this biographical sketch, equally numerous. He was member of a very large number of learned societies both at home and abroad, and at the great meeting of the British Medical Association in London in 1895 was President of the Section of Surgery. In that capacity he delivered one of the most universally interesting addresses of the meeting, taking for his theme his favourite subject of the advance of war surgery with special reference to the effects of modern projectiles.

Sir William MacCormac married in 1861 Katherine, daughter of Mr. John Charters of Belfast, who survives him. He leaves no children.

Sir William MacCormac had suffered for the last two or three months from insomnia, depression, and vague pains in the back, but his sudden death from cardiac failure has come as a great surprise to the medical profession. Only his intimate friends and medical advisers considered him to be in a serious state of health.

The funeral will take place on Monday next at Kensal Green Cemetery.

#### ARCHIBALD CAMPBELL CLARK, M.D. EDIN., F.F.P.S. GLASG.

WE regret to announce the death of Dr. Campbell Clark, which took place at his residence, Hartwood, Glasgow, on Nov. 28th. Dr. Clark had been in declining health during the last year, having had a somewhat severe attack of influenza which was followed by visceral complications, to which he eventually succumbed. Dr. Clark was a distinguished student at the University of Edinburgh, where he took his degree of M.D. with honours in 1886. After having been for a few months assistant medical officer at the Melrose Asylum, he joined the staff of Morningside Asylum, under Dr. T. S. Clouston. At a comparatively early age he was appointed medical superintendent of the Glasgow District Asylum at Bothwell, where he soon distinguished himself by original research and literary work and laid the foundation of his reputation as one of the foremost alienist physicians of the day. While superintendent of the Bothwell Asylum he was chosen for the superintendency of the new

asylum for the county of Lanark to be built at Hartwood, and he was for several years engaged in connexion with the plans of the new asylum and in the superintendence of its erection and equipment. The asylum, which was opened about six years ago, remains a monument to his genius for organisation and to his mastery of the principles governing the humanitarian treatment of the insane. In the happy combination of simplicity of design, adaptation of means to ends, and economy of construction, Hartwood Asylum is remarkable. Dr. Clark was the pioneer of the latter-day movement for the scientific training of attendants upon the insane and was joint author of a practical manual on the subject. His contributions to medical science were varied and important and always characterised by originality, his treatise upon the "Etiology, Pathology, and Treatment of Puerperal Insanity" embodying clinical observations of abiding value, and his work in connexion with experimental dietetics in lunacy practice being of the most brilliant character. His *magnum opus*, however, was "A Clinical Manual of Mental Diseases," published in 1897. He held the post of Lecturer on Psychological Medicine at St. Mungo's College, Glasgow, and was President of the Caledonian Medical Society, which held its annual meeting in Glasgow in August last. The fact that it was prepared on a sick bed lent a pathetic interest to his presidential address on that occasion. Dr. Clark was a man of generous character and wide sympathies, and his death will be deplored as a personal loss by his many friends, and also in the wider circle of those to whom he had held out a helping hand in time of distress and adversity.

**DEATHS OF EMINENT FOREIGN MEDICAL MEN.**—The deaths of the following eminent foreign medical men are announced:—Dr. Bohoslav von Jirus, Professor of Pharmacology in the Bohemian University of Prague, at the age of 60 years.—Dr. Giuseppe Chiarleoni, Professor of Medical Pathology in Palermo.

## THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THE proceedings of the General Medical Council came to a conclusion on Tuesday afternoon, Dec. 3rd.

Those who best know the work and the working of the General Medical Council anticipated that the late session would be a short one. They expected that it would last five days and end on Saturday, Nov. 30th. They have been mistaken. The Council sat seven days instead of five, and has something to show for the time and the money spent. In our opinion the really interesting and important work might easily have been done in five days with advantage to the Council's finances, but we do not lay stress on this, preferring to be thankful for the progress made.

Readers of the Life of Sir James Paget will have noticed that he disliked the work of the Council. Doubtless his dislike was due to its constitution and the limitations of its power. Those who have been accustomed to office in smaller and more compact bodies, with definite functions and absolute power within the limits of those functions, naturally feel unwilling to spend session after session in discussing the same subjects somewhat academically. This is what members of a complicated body whose resolutions only amount to recommendations, and have to be framed so as to please all the consenting parties, are forced to do. This fact is much concealed in the Council by the general sense of responsibility of the various members and by their perception of the fact that they are mutually indebted to each other for sound suggestion in matters affecting all the bodies in common and medical education in particular.

Unless the sense of public responsibility and of the unseemliness of differences between bodies with similar functions grows there can be little doubt that the authority and credit of the Council will suffer seriously.

The business of the Council in the session which has just closed was, in fact, extremely simple. It was divisible as usual into two chief parts—one having reference to the disciplinary function of the Council and the other to its action as a council of medical education. The Council appeared to great advantage in the discharge of the first part of its business. The proceedings were grave and full of consideration for the practitioners implicated. The case of the Scottish practitioners charged with employing as assistants for the sale of scheduled poisons persons not qualified to act as pharmaceutical assistants and thereby causing such persons to commit breaches of the Pharmacy Act was very important. The proceedings were much simplified by the dignified action of the accused practitioners who, at an early stage of the inquiry, expressed their regret at the custom complained of and made it easy for the General Medical Council to close the case at once. The degree in which registered medical practitioners can compete with pharmaceutical chemists in the sale of ordinary drugs has not been settled by this decision of the General Medical Council. This is a point which must be left meantime to the judgment and the taste of registered medical men, and to their sense of what is due to the great profession of which they are members. But it was clearly impossible for the General Medical Council to allow registered practitioners to infringe, or even to appear to infringe, the law as to the sale of poisons.

Not at all less important, whether viewed in its professional or public aspects, is the case of Dr. Robert Rendall, M.B., C.M. Edin., who had been summoned before the General Medical Council charged with "having accepted and continuing to hold the appointment of medical officer to the Liverpool Victoria Legal Friendly Society at Great Yarmouth, a society which systematically practises canvassing for the purpose of procuring patients, and with approving and acquiescing in such canvassing." The particulars will be found fully reported in our present number and may be assumed to be familiar to our readers. The gravity of the charge against the medical practitioner involved may be gathered from the eminence of the counsel engaged to represent him, and, as we have said in a leading article upon the situation, it is no small testimony to the ability with which the case was conducted by Dr. A. G. Bateman that in spite of the opposition of such counsel he secured all his points.

Among the most important acts of the Council was the appointment, on the motion of Dr. McVail, seconded by Mr. Young, of a Special Committee to prepare a report on the differences between certain licensing bodies on the one hand and the General Medical Council on the other. The questions at issue have regard to the conditions of preliminary study and the institutions and schools in which the required courses may be taken. The report will be considered at a special meeting of the General Medical Council, when the Council will decide what action shall be taken, and especially on the question of an appeal to the Privy Council. This resolution promises to make the recent session of the Council a memorable one. The majority by which it was carried was substantial, but the minority included members who cannot be disregarded, and not a few who do not sympathise with the Conjoint Board of England in their refusal to submit their list of institutions for teaching the

ancillary sciences for approval by the General Medical Council. It is not easy, after all that has passed, to see how the Special Committee can stop short of recommending an appeal to the Privy Council, but the step is so serious and the justification of it so doubtful that we venture to hope that some other way out of the *impasse* may even yet be discovered.

Sir William Turner was re-elected President of the Council unanimously for a further term of five years.

THURSDAY, NOV. 28TH.

THE Council met and resumed the work of its winter session, Sir WILLIAM TURNER, President, being in the chair.

*Great Yarmouth Club Question: the Case of Dr. Robert Rendall.*

The first business was the consideration of the case of Robert Rendall, of 19, St. Peter's-road, Great Yarmouth, registered as M.B., Mast. Surg. 1893, Univ. Edin., who had been summoned to appear before the Council to answer the following charge as formulated by the Council's solicitor:—

That you have been guilty of infamous conduct in a professional respect, particulars of which are that you have accepted and continue to hold the appointment of medical officer to the Liverpool Victoria Legal Friendly Society at Great Yarmouth, a society which systematically practises canvassing for the purpose of procuring patients, and that you have approved or acquiesced in such canvassing.

Dr. A. G. Bateman, with Mr. Hempson, attended to conduct the case for the Medical Defence Union who were the complainants.

Dr. Rendall had for his legal representatives Mr. Lawson Walton, K.C., M.P., and Mr. Charles Matthews, instructed by Mr. J. Tickle, solicitor.

Mr. WINTERBOTHAM, solicitor to the Council, read the terms of the charge.

Dr. BATEMAN, in opening the case for the complainants, said that questions were raised here which were of the very greatest import, not only to the medical profession, but also to certain societies like the Liverpool Victoria Legal Friendly Society and the National Medical Aid Company. The case turned upon the question raised by the resolution of the Council of June 6th, 1899, in which they expressed strong disapproval of medical practitioners associating themselves with medical aid associations which systematically practise canvassing and advertising for the purpose of procuring patients. The system of these medical aid societies was to plant themselves in a city or town and send their agents canvassing for patients from door to door quite irrespectively of whether the people in the houses were or were not able to pay ordinary medical fees and quite irrespectively of whether or not they already had a medical attendant. Where the medical practitioners in the district agreed to this arrangement there was no difficulty, but where they disagreed and objected to acting for these societies then men from the outside were planted in the district. Many complaints were of course received and the Council inquired into the subject and in the end passed the resolution to which he had referred. After that the National Medical Aid Company found it exceedingly difficult to obtain medical officers, and what he was directed to say was that they associated themselves with the Liverpool Victoria Legal Friendly Society, a society which was a sort of burial club or insurance society. The result was that the persons who were canvassed for insurance were also canvassed for medical aid; they were asked would they not like to join the "doctor's club" as well as the life insurance. In this case Dr. Rendall's club was a branch of the National Medical Aid Company. It might be said that Dr. Rendall's club did not canvass and that therefore Dr. Rendall could not be brought within the terms of the resolution, but it would be seen that Dr. Rendall's name had been specifically mentioned in the advertisements. In the case of Mrs. Wilkins she was asked to put herself and her baby into Dr. Rendall's club; the canvasser said it was Dr. Rendall's club. In other instances there was distinct evidence of touting on behalf of Dr. Rendall. In one case the canvasser said to the woman that the more members the better for Dr. Rendall. One person asked whether she could join the burial club without joining the "doctor's club" and she was told that she must join both or none. It might be said that

the canvassers acted without the authority of the society, but that was no defence here because the moment Dr. Rendall heard of the affair it became his duty to resign. Dr. Rendall could not, moreover, plead ignorance, for the practitioners of Yarmouth had been at great pains to bring the facts before him and to persuade him to give up the appointment.

Mr. WILLIAM EDWARD WYLLYS, L.R.C.P., L.R.C.S. Edin., of Great Yarmouth, then gave evidence in terms of a statutory declaration he had made on April 27th, 1901. He explained that in March, 1896, the practitioners residing in the Yarmouth portion of the borough of Great Yarmouth with one exception united in a local medical association called the Great Yarmouth District Committee. At the time three industrial assurance companies were actively conducting medical aid work in the town—namely, the London and Manchester Assurance Company, the Liverpool Victoria Legal Friendly Society, and the Refuge Assurance Company. Each society, he was informed, had a different system of working its medical aid branch, but the effect was the same so far as the canvassing was concerned; the private patients of practitioners were solicited directly for the insurance company and indirectly for the medical officer attached to the medical aid branch. All the members of the local medical association who held or had previously held appointments of this nature were satisfied that when medical aid was managed by these industrial assurance companies as an adjunct to their ordinary business it was impossible for either the medical officer or the company to prevent their agents, who were paid by commission on the amount of the business introduced by them, from using the medical aid as an inducement to attract custom to the life insurance department. From the very formation of the local medical association it was unanimously agreed that no member should canvass, or knowingly permit others to canvass on his behalf, for patients and that no member could therefore consistently act as medical officer to any of the medical aid departments carried on as described. Mr. Charles O'Farrell resigned the position of local medical officer to the London and Manchester Assurance Company, but the company appointed another gentleman whom they brought into the town for the purpose. This gentleman left shortly afterwards and the position was then taken over by Dr. Herbert Collier who thereupon became medical officer to all the medical aid societies conducting business in this part of the borough of Great Yarmouth. After the passing of the resolution of the Council in 1899 Dr. Collier wrote to him as secretary of the local medical association that in view of the resolution he felt obliged to resign the whole of his appointments. The London and Manchester Assurance Company and the Refuge Assurance Company at the expiration of Dr. Collier's six months' notice abandoned the medical aid section of their business. The Liverpool Victoria Legal Friendly Society did not, however, follow that course. Dr. Rendall succeeded Dr. Collier as the medical officer to the company and its auxiliary company, the National Medical Aid Society. As the medical aid work carried on by the Liverpool Victoria Legal Friendly Society through its auxiliary company and Dr. Rendall, its medical officer, was in the opinion of the local medical association contrary to the resolution of the Council, on May 18th, 1900, witness, acting as secretary, wrote to Dr. Rendall calling his attention to the objectionable features inseparable from his appointment. Dr. Rendall subsequently saw the president of the association and witness and discussed the position. In view of the fact, however, that Dr. Rendall was bound by his engagement to act as medical officer for 12 months from the date of his appointment no definite action was taken by the local medical association. The 12 months expired in February last. On Dec. 19th, 1900, witness wrote to Dr. Rendall inquiring if he intended relinquishing his appointment on the expiration of the 12 months, but nothing satisfactory had been arranged and Dr. Rendall still retained the appointment. At the interview with Dr. Rendall it was pointed out to him that the body for whom he was acting was supported by a general indiscriminate canvass by paid canvassers, that the medical aid branch was used as an attraction to induce people to take life policies, and that other members of the local profession had previously held the same appointment but had relinquished it in consequence of the resolution of the General Medical Council and in deference to the opinion of the Great Yarmouth District Committee. In reply Dr. Rendall denied that there had been systematic canvassing

and stated that the agents of the society worked only amongst the poor and that he had the power of refusing any candidate whom he deemed unfit by reason of his state of health or of his social position. On June 11th, 1900, Dr. Rendall wrote to say that he had carefully questioned the agent and collectors and they all strongly denied that there was any systematic canvassing carried on.

In cross-examination WITNESS said that in the letter of June 11th, 1900, Dr. Rendall asked to be furnished with the names of the party or parties who were alleged to have been canvassed, but witness did not think that the association would have been justified in giving up the evidence in its possession.

Mr. A. H. MOXON, ex-president of the local medical association, who was present at the interview with Dr. Rendall, gave an account of what took place.

Dr. BATEMAN then read a number of statutory declarations as to alleged instances of canvassing by agents of the society and as to what was printed on "the doctor's card." He also read a declaration by Mr. Charles O'Farrell, L.R.C.P., L.R.C.S. Edin., of Norfolk-square, Great Yarmouth. Mr. O'Farrell said that he was satisfied from his experience that where medical aid departments were managed by industrial life insurance companies as an adjunct to their business it was quite impossible for either the medical officer or the company to prevent the agents from using the medical aid as an inducement to a tract members to the life insurance department. Dr. Herbert Collier, of 21, South Quay, Great Yarmouth, made a declaration to the same effect, as also did Dr. Henry Blake, of Regent-road, Great Yarmouth. Mr. George Horne, local superintendent at Great Yarmouth of the Refuge Assurance Company, stated in a declaration that policy-holders had permitted their policies in that company to lapse and joined the Liverpool Victoria Legal Friendly Society, giving as a reason that the latter offered medical aid to its members.

This completed the case for the Medical Defence Union.

Mr. LAWSON WALTON then addressed the Council for Dr. Rendall. He contended that the resolution of 1899 was not intended to proscribe medical aid associations, but only to put down systematic canvassing for patients and he submitted that in this case there had been nothing which could be so described. The friendly society and the medical aid society were distinct entirely in their origin and history. The latter made no profits. Of the money collected 80 per cent. went to the medical officer, 10 per cent. was represented by the expenses of collection,  $7\frac{1}{2}$  per cent. by office expenses, stationery, &c., and  $2\frac{1}{2}$  per cent. by central management expenses. The staff of agents and collectors were engaged for the insurance business and were paid for the work they did in that connexion and not for the work in connexion with the medical aid society. Not only so, but the staff were expressly told that they must not canvass for the medical aid society. When complaint was made as to alleged canvassing Mr. Cully, the district manager, called the collectors together and questioned them, and they insisted that there was absolutely no foundation for the allegations. Dr. Rendall also saw them and they made the same denial to him. Further, he thought the correspondence showed that from the first Dr. Rendall was perfectly honest in discountenancing canvassing and in his desire to act within honourable professional lines.

Mr. PETERS, chief clerk to the Liverpool Victoria Legal Friendly Society, was the first witness. In examination by Mr. MATTHEWS he said that the membership of the Liverpool Victoria Legal Friendly Society was about 2,500,000, and that of the National Medical Aid Company 150,000. The medical officers employed numbered about 2000. There were no canvassers for the medical aid society, only collectors for the friendly society, and the instructions to these were that they were not to do any canvassing for medical aid.

The PRESIDENT called witness's attention to a card of the National Medical Aid Company which contained the name of the district and spaces for the name of a collector and a medical man. Witness explained that the name of a medical man would be written in by the collector, but only after a person joining the Victoria had elected to have medical relief. The collector collected for both societies, and both paid him something. He got his collecting commission from the Liverpool Victoria Legal Friendly Society and a small percentage from the National Medical Aid Company.

Further examined by Mr. MATTHEWS: The entrance fee of the National Medical Aid Company was 6d. and the charge for the card was a penny. The Victoria was a friendly society

entirely. It was not a business carried on for profit. The medical aid society was conducted on the same principles.

Cross-examined by Dr. BATEMAN: It was quite possible that the collector started out with a policy in one pocket and a card in another. The cards were supplied from the London office. There had been some difficulty since the war in getting medical officers. When there were vacancies for them these were not advertised in the medical papers but in the public newspapers. The latter and not the former, he thought, were the best for getting men for their vacancies. The advantages of medical aid were generally brought to people by neighbours who were members recommending others to join.

By Sir WILLIAM THOMSON: Any person could be a member of the medical aid society, although not insured in the Victoria.

By Mr. TOMES: Although there were 2000 medical officers for the Victoria that did not mean that every medical man connected with the Victoria also did work for the medical aid society.

By Dr. LOMBE ATTHILL: Witness had not calculated how much the 10 per cent. of payments from 150,000 members which went for the management amounted to. He would take it that the sum would reach about £3650, and he would also take it that the 2½ per cent. which the management got would amount to £900 or so a year.

By Mr. MUIR MACKENZIE: He had not brought details, but he thought that the percentage of persons insured in the Yarmouth branch of the Victoria who were also members of the medical aid society would be a little higher than the general 6½ per cent., because Dr. Rendall was very popular.

By Dr. GLOVER: A suggestion from a collector to join the medical aid society would be contrary to instructions. The object in establishing that society was a purely philanthropic one. Doubtless there were Foresters and Oddfellows among the members of the society, as there was no hindrance to such joining it. He was not aware that some friendly societies had given up their medical aid branch after becoming aware of the Council's resolution on the subject.

Re-examined by Mr. MATTHEWS: Experience had shown that the 10 per cent. for collection was actually required, and there had been no profit; consequently there was absolutely no motive for the Victoria Society to extend the medical aid business. There was not a single person who could canvass for the medical aid society without breach of duty, and as a director he had to say that his board were doing their best to conform to the requirements of the General Medical Council.

Mr. WILLIAM CULLY, district manager at Great Yarmouth of the Liverpool Victoria Legal Friendly Society, and also manager for the National Medical Aid Company, stated that on receiving from the head office in London intimation of the General Medical Council's resolution on the subject of medical aid associations he had called a meeting of his collectors and had read the letter to them. When correspondence about Dr. Rendall's position arose he questioned the collectors, and all of them utterly denied any instance of canvassing for medical patients. There had been no canvassing for the medical aid society, and that was in obedience to his orders. The people who belonged to the society were very poor, earning perhaps from 10s. to 20s. a week.

Cross-examined by Dr. BATEMAN: Witness did not think that the collectors for the Victoria Society asked whether members of that society required medical aid, neither did he think that the collectors showed the card of the medical aid society. It became known in a general way that the Victoria Society had a medical aid society connected with it, and new members were brought through recommendation only.

A large number of the witnesses I brought forward to-day have proved that these people had their own doctors?—I cannot account for it.

Asked by Dr. GLOVER how the society in Yarmouth managed to confine themselves to the poor, witness replied that it was only natural that the collectors should go to the poorer class, because the money that had to be paid was so small. The society, however, did not give any instructions to avoid the better-class houses; in fact, they gave the collectors a free hand.

By Sir JOHN TUKE: About 2000 of the members of the Victoria Society in Great Yarmouth belonged to the medical aid society. The income was about £475 a year, but two medical men had to be paid out of that.

By Mr. BALL: Persons joining the medical aid society were not entitled to benefit until they had paid for seven weeks.

By Dr. LITTLE: Such persons must be persons earning not more than 30s. a week.

The PRESIDENT: Are we to understand that there is a wage-limit?

The WITNESS: We are not allowed to take people with wages above 30s. a week.

By Mr. HORSLEY: He could not say if this wage-limit applied to all districts or to Yarmouth alone. He thought that instructions were given from headquarters that they were not to take persons earning more than 30s. a week. Asked how he ascertained the earnings of the people he replied that, as a rule, he asked them about their income when he visited in order to verify the collector's report that they had joined the medical aid society.

By Dr. BRUCE: Have you ever struck a man out because of the wage-limit?—I do not know.

By the PRESIDENT: The society did not require Dr. Rendall's whole time and service. They did not interfere with his private practice.

Re-examined by Mr. MATTHEWS: One of the rules was that no person could join the medical aid society unless he was healthy, and he could not get benefit until after seven weeks. It was no advantage to the Victoria Society to run the medical aid society. He personally got 2½ per cent. of the income and beyond that he had no interest in it whatever.

In answer to Mr. HORSLEY, who asked who was the judge of good health, witness stated that the collectors' instructions were that they were to see each person; then he saw each person for himself, and if there was any doubt about the healthiness of anyone he sent a report to the medical officer who had the power of rejection.

By Mr. MATTHEWS: Have you ever heard it suggested that any of your collectors put a person on the benefit at once?—No, sir; I have never sanctioned anything of the kind.

Mr. PETERS, recalled, and questioned as to whether the central board of the National Medical Aid Company had issued instructions to their district managers that they were not to accept members unless their earnings were below 30s. a week, stated that verbal instructions had been given respecting the matter just as occasion arose. In the case of Mr. Cully witness believed that that gentleman was informed that he must not take cases above a certain limit. 30s. was Mr. Cully's limit for his district. The central board must leave the fixing of the limit to the local managers. It would be impossible for the board to fix a general wage-limit and none had been fixed by them.

By Dr. LITTLE: Some of the directors of the Victoria Society were also directors of the medical aid society.

By Dr. GLOVER: There were two London offices, but he would not call the one commercial and the other philanthropic. He would call them both the same—mutually friendly. The aid society had been formed in a time of emergency as a company and it had remained a company ever since, though not in the commercial sense.

By Mr. TOMES: They were under the Companies' Acts.

By Sir WILLIAM THOMSON: There were no shareholders in the Victoria Society. There was a committee of management, of which each member was paid salary as voted at the annual meeting of the society. The directors of the medical aid society were paid a small sum for their attendance at the board.

Dr. RENDALL was next examined. In answer to Mr. WALTON he stated that he had practised in Edinburgh, Ipswich, and the north of Scotland. Then he came to London and when looking out for an appointment obtained the one which he at present held at Great Yarmouth through an advertisement in a daily newspaper. So far as he was aware, in the work which he was carrying on he was not interfering with other medical men in the district. The class of people who received benefit through the medical aid society was not the class who would pay medical fees. He had been very distinctly assured by the local manager of the Victoria Society that there was no canvassing by the collectors of that society for medical relief members. He had received a similar assurance personally from each of the canvassers of that society. Moreover, he had frequently asked his patients if they had been canvassed, and they said that they had not; that they had been recommended by neighbours. When the Council's solicitor

wrote to him he emphatically denied the suggestion that he had approved or acquiesced in canvassing for patients, systematically or in any other way. He certainly had not had the slightest wish to utilise the insurance machinery to secure private patients for himself.

Cross-examined by Dr. BATEMAN: In his interview with local medical men it had not been put to him directly that practitioners who had held office under the Victoria Society had resigned because, after the action of the General Medical Council as regards medical aid associations, they could not continue in office. He might have gathered that, but not distinctly. He had never taken any great interest in the question of medical aid societies. The salary he got for the first year he was in Yarmouth was about £150.

By Mr. HORSLEY: He was not quite aware that there was a wage-limit in Yarmouth, but Mr. Cully had told him of the class of people he would have as patients. Mr. Cully had not stated any sum, but had said that if witness found any applicants for aid able to pay medical men's fees he was at liberty to strike them off his list.

The further hearing of the case was then put off until the next day, and

The Council adjourned.

FRIDAY, NOV. 29TH.

The Council met again, Sir WILLIAM TURNER presiding.

#### A Dental Case.

The Council proceeded to the further consideration of the case of Mr. Alexander Wood Donaldson, dentist, of 86, Whiting-street, Bury St. Edmunds, who was registered in the Dentists' Register as having been in practice before July 22nd, 1878. The Dental Committee reported that Mr. Donaldson had advertised himself for many years with the description R.D.S. R.C.S. Eng., and subsequently with the description R.D.S. Eng., but had apologised for what he had done, stating that he had erred through ignorance, and that he had withdrawn all descriptive letters from his advertisement and undertook not to use them in the future.

After the Council had sat *in camera* for a time the PRESIDENT announced that the Council, taking note of Mr. Donaldson's pledge with respect to the withdrawal of the false description which he had been in the habit of advertising and of his expression of contrition for the offence he had committed, had decided to proceed no further in reference to the facts proved against him.

#### The Degrees of Italian Universities: Recognition by the Council.

Discussion was resumed on the report of the Executive Committee on the medical degrees of the Italian universities. The report was in these terms, viz.:—

The Executive Committee report that Part II. of the Medical Act, 1886, having been applied to Italy by an Order in Council dated March 9th, 1901, application was made to the Privy Council, at the suggestion of the Education Committee, requesting that the Council might be supplied through the proper official channels with such information as to the existing regulations for medical qualifications in Italy as would enable the Council to fulfil its statutory duties under Section 13 (1) of the Medical Act, 1886.

This information having been supplied by the Privy Council, the committee have carefully examined the Royal decree of Oct. 8th, 1876, which applies to all Italian universities, and, having satisfied themselves that the regulations provide a sufficient guarantee of the possession, by Doctors of Medicine and Surgery of these universities, of the requisite knowledge and skill for the efficient practice of medicine, surgery, and midwifery, have resolved:—

"(1) That the degree of Doctor of Medicine and Surgery of all Italian universities should be recognised as entitling to registration in the Foreign List of the Medical Register.

"(2) That with reference to applications from Italian medical graduates for registration in the Foreign List, the Registrar be instructed to require the applicant to produce:—

- "(a) Satisfactory evidence of identity;
- "(b) Satisfactory evidence of good character;
- "(c) Satisfactory evidence that he is by the law of Italy entitled to practise medicine, surgery, and midwifery in that country;
- "(d) The diploma of Doctor of Medicine and Surgery of an Italian University;
- "(e) Satisfactory evidence in relation to the circumstances (1), (2), (3), set forth in Section 12 of the Medical Act, 1886."

[The circumstances referred to in Section 12 of the Act of 1886 are that the applicant is not a British subject, or that being a British subject the diploma or diplomas was or were granted to him at a time when he was not domiciled in the United Kingdom or in the course of a period of not less than five years during the whole of which he resided out of the United Kingdom, or that being a British subject he was practising medicine or surgery or a branch of

medicine or surgery in the United Kingdom on the said prescribed day and that he has continuously practised the same in the United Kingdom or elsewhere for a period of not less than 10 years immediately preceding the said prescribed day.]

Mr. HORSLEY moved that the report be referred back to the committee.

Dr. BRUCE seconded the motion.

Mr. HORSLEY said that although he considered that in this matter the Council had been treated by the Government with the grossest disrespect and contempt, he, of course, recognised that they were under the harrow and must submit. When they were ordered by the Government to do this thing they had no option but to comply provided they did their duty towards those gentlemen in the same way as they did towards the gentlemen who were educated in the universities of this country. In this report the Executive Committee said that they had come to the decision that the regulations of the Italian universities provided a sufficient guarantee of a person's qualifications to be entered upon the Register. Now he urged that no regulations by themselves could provide such a guarantee. In the case of the universities of this country the Council did not accept regulations as a guarantee, for they inspected and visited the examinations, and he wished to know whether the Executive Committee proposed to inspect and visit the examinations of the Italian universities. The scheme of these Italian regulations was constructed in 1876, since which year a good deal of water had flowed under the bridge. In this country they had entirely altered the curriculum. As to the conditions which the committee had applied, he did not think that they were at all satisfactory and, indeed, in his opinion, they were not worth the paper on which they were written.

Dr. MACALISTER said that although the regulations were dated originally in 1876 they had been revised from time to time since by royal decrees, and had really been brought up to date. As for the conditions to which Mr. Horsley took exception, they simply followed the lines laid down in the Act and they were not the choice of the Executive Committee. The regulations of all the Italian universities were on the same level and were laid down by the law of the land, so that there was no question of discriminating between one university and another. It was true that they did not propose to inspect the examinations, but they registered Indian and Colonial degrees without inspection of the examinations. If this Council were to refuse recognition merely because they could not inspect, the practitioner who applied was empowered by law to appeal to the Privy Council who might order this body to recognise the diploma.

Dr. GLOVER thought that Mr. Horsley should indicate what he proposed the Executive Committee should do. He was sure that all members felt that the mere reading over of regulations was a very unsatisfactory way of testing the sufficiency of an examination.

Mr. HORSLEY said that in his opinion colonial questions were not to be placed on the same platform as foreign questions. Foreigners did not treat us in the same way as our colonists and therefore they did not deserve the same treatment upon our part. As to inspection, if the Privy Council chose to order this Council to take up certain duties, the responsibility was upon the Privy Council and so upon the Treasury to provide the necessary expenses for those duties. The Council could not derive from the income which they drew from the registered practitioners of this country the money necessary for the inspection of the Italian universities and he maintained that this point should be laid before the Privy Council and that direct application should be made to it to defray the expenses of their inspection of the Italian universities.

Dr. McVAIL suggested that the opinion of their legal advisers should be taken as to whether they considered that inspection was a duty of this Council under the Act.

The PRESIDENT said that the sufficiency of the examination was a matter for the decision of the Council.

Mr. HORSLEY said that the Act of 1886 clearly laid down that the whole responsibility for recognising a diploma rested upon the shoulders of this Council and he contended that if they felt that responsibility to the universities in this country to the extent that they were obliged to inspect them, *a fortiori* they ought to inspect the Italian universities.

A vote was then taken, when 10 members voted for Mr. Horsley's motion to refer the report back to the committee.

and 11 voted against it, seven members declining to vote and three being absent. The motion was accordingly lost.

#### *The Standard of Preliminary Examinations.*

The Education Committee presented a second report on the steps taken for the improvement of preliminary examinations. In this report reference was made to steps taken in connexion with the examinations of the College of Preceptors, the Educational Institute of Scotland, and the Royal Colleges of Physicians and Surgeons in Ireland, and the committee proposed for the adoption of the Council the following list specifying the examining bodies in Great Britain and Ireland whose examinations in general education would be recognised by the Council as qualifying for the registration of medical or dental students from Jan. 1st, 1902, viz. :—

#### **I.—UNIVERSITY EXAMINATIONS HELD IN THE UNITED KINGDOM.**

##### **A.**

Final Examination for a Degree in Arts or Science of any University in the United Kingdom.

##### **B.**

##### *University of Oxford.*

Junior Local Examinations. (Certificate to be endorsed as fulfilling the Council's requirements.)

Senior Local Examinations. (Certificate to be endorsed as fulfilling the Council's requirements.)

Responsions. (Certificate to be supplemented by others showing that the required mathematical subjects have been passed.)

Moderations. (Certificates to include the required subjects.)

##### *University of Cambridge.*

Junior Local Examinations. (Certificate to be endorsed as fulfilling the Council's requirements.)

Senior Local Examinations. (Certificates to be endorsed as fulfilling the Council's requirements.)

Higher Local Examinations. (Certificates to include the required subjects.)

##### *Royal Colleges of Physicians and Surgeons in Ireland.*

Preliminary Examination. (The required subjects to be passed at one time.)

Sir JOHN BATTY TUKE in moving the adoption of the report gave a general account of the work of the Education Committee in this connexion. He said that it had been found impossible in the present state of secondary education in this country to raise the standard to that of the senior or higher grade examinations, but they had done a good deal to improve generally the quality of the examinations which they recognised. They had invited the various examining bodies to substitute to a very much greater extent than previously unseen books for prepared books, and to raise the standard of pass marks rather than to increase the apparent difficulty of the examination, and they had met with very great success in the establishment of these two principles all along the line. He might be asked whether the committee saw a chance of giving effect to a further rise in the quality of the examinations, and his answer would be that it was hopeless in the present chaotic condition of secondary education in this country. The responsibility rested with the Government, and he sincerely hoped that during next session of Parliament they would bring forward a strong and satisfactory measure which would benefit not only the medical profession but the country at large. In his opinion the Education Committee had done as much as it was possible to do in the circumstances and had made a very material advance in the improvement of the standard of the preliminary examinations. There was, however, a sad side of the question. It was quite possible that all their work might be futile because he noticed that in the regulations of the Conjoint Examining Board in England for 1902 it was stated that students were required to complete five years of professional study after passing a recognised preliminary examination and this preliminary examination was as recognised not by this Council but by the Examining Board. It was possible that the Examining Board would adopt the list of examinations now put forward by the Education Committee; it was possible that it might not; but it must be always remembered that it was open to anybody to do exactly as this Board proposed to do so far as their individual recognition of preliminary examinations was concerned. It was with a considerable amount of regret and sorrow that he saw this regulation, because he felt that the work which had engaged the attention of the Education Committee for the last five years might be rendered useless and futile.

Sir CHRISTOPHER NIXON seconded the motion. The announcement just made of the determination of the English Royal Colleges to adopt a list of recognised examinations of their own without any reference to the requirements of this Council was new to him and, he fancied, also to the other members of the Education Committee.

Dr. NORMAN MOORE said that there was no ground whatever for the statement which had just proceeded from Sir John Tuke; the subject had not even been considered by the Royal College of Physicians of London.

Sir JOHN BATTY TUKE said that he based his statement on the regulations supplied by Dr. Norman Moore last year for the information of the Council.

Dr. NORMAN MOORE insisted that there was nothing in these regulations which bore the interpretation put upon them by Sir John Tuke.

Sir JOHN BATTY TUKE, reading from the regulations, said that the student would be required to produce before admission to the several examinations a certificate of having

passed one of the preliminary examination in general education recognised by the Examining Board, a list of which might be obtained on application.

Mr. YOUNG said that the matter was not so new as Sir Christopher Nixon imagined, because he (Mr. Young) read out this paragraph at the last session of the Council and called attention to its importance. It might be that the Royal Colleges did not intend to depart from the list of this Council, but the point was that they claimed the power to depart from it at any time that they thought fit and consequently there was no guarantee that the standard of preliminary education would be maintained.

Dr. NORMAN MOORE, speaking for the Royal College of Physicians of London, said that they had the right, and they intended to retain it, of saying what should be the conditions of admission to their licence. They absolutely retained that in the fullest degree. They had not, however, discussed the question of having any other regulations with regard to the preliminary examination than those to which this Council had agreed. He would like to explain the clause read out by Sir John Batty Tuke. The Council had endeavoured to encroach upon the undoubted right of the Royal College of Physicians of London and of all the other qualifying bodies to see where the people had studied who proceeded to their licence. It therefore became necessary to frame their regulations in such a way as clearly to show that when they carried out the precise regulations of the Council they did not in the least give up any of these duties which were theirs before the regulations of the Council were made. He did not doubt that the qualifying bodies throughout the United Kingdom complied with the regulations of this Council because they had been so clearly demonstrated to be wise and just and in accordance with the best interests of education, but if they could suppose for a moment that, say, 20 years hence, the Council made some extremely unwise regulations in regard to education, would the Royal College of Physicians of London and the other qualifying bodies agree merely because they were the edict of this Council? No qualifying body could give up its responsibility. Its decision might be to follow exactly what this Council said, but none the less that was the result of its own judgment. With regard to this report of the Education Committee he cordially supported it. There was one detail, however, which he thought might be amended, and he moved, after the words "University of London, matriculation examination," to omit the words "certificate to include the required subjects." He thought that it would be wise to omit these words until the University of London had been communicated with.

Mr. BRYANT seconded this amendment.

On the motion of Dr. PAYNE the discussion was adjourned until next day.

*The Great Yarmouth Club Question: the Case of Dr. Rendall.*

Consideration of this case was then resumed.

Dr. Rendall appeared for further examination.

Mr. HORSLEY asked witness whether, when he received the names of persons who had furnished the Medical Defence Union with declarations, he went to those persons and asked them if they had been canvassed.

The WITNESS replied that he did not do so, but left inquiries to be made by his solicitor, Mr. Tickle. He did not know whether Mr. Tickle acted for the medical aid society.

Mr. HORSLEY reminded the witness that in a letter which he addressed to the President of the General Medical Council he offered to resign if a case of canvassing was made out, and inquired of Dr. Rendall if he had asked his solicitor whether these persons were canvassed.

The WITNESS said that he had. His solicitor had reported, but not in writing. He had been told through the solicitor's clerk that a number of persons alleged to have been canvassed had not been canvassed. He had not inquired as to whether all these persons were included and he had not visited any of them himself. He had not resigned because he considered that the allegations of canvassing had not been proved.

By Mr. MATTHEWS: It was not until Nov. 13th that any case of canvassing had been suggested officially, and the result of the inquiries which had been made showed that the declarations obtained by the Medical Defence Union contained statements which were untrue.

Three collectors for the Liverpool Victoria Legal Friendly Society—Mr. Harry Savell Mann, Mr. William Willett, and

Mr. Charles Walter Newark—were called next, and in turn they declared emphatically that they had carefully carried out Mr. Cully's instructions against canvassing for medical aid members or on behalf of Dr. Rendall. They also asserted that the allegations of canvassing by them made in the declarations put in by Dr. Bateman were absolutely untrue.

In answer to the PRESIDENT, Mr. NEWARK stated that when members were admitted to the insurance society for a small sum they did not need to undergo a medical examination. He believed that Dr. Rendall acted for both the insurance society and the medical aid society.

Several declarations were read by Mr. MATTHEWS and put in. These contained statements conflicting with the allegations in those submitted on behalf of the Medical Defence Union to the extent of showing that instead of members for the medical aid society being obtained by direct or indirect canvassing they were got by neighbourly suggestion or recommendation.

Mr. PETERS, who was recalled at the request of Dr. PETTIGREW, explained that the National Medical Aid Company was composed of 10 or 11 shareholders who got an annual present of about £10 each for directing affairs. About 1000 doctors did work for the company. He was secretary to the company and also a director of it.

This concluded the evidence.

The PRESIDENT said that as this case had evidently been made a test one—he did not think there would have been such an array of counsel otherwise—it had been resolved, although contrary to the usual procedure in penal cases, to hear anything in the nature of argument which Mr. Lawson Walton would care to urge and to allow Dr. Bateman an opportunity to reply on the whole case.

Mr. LAWSON WALTON thereupon submitted that the charge as framed against Dr. Rendall had not been proved. The evidence in support of it came from a class of persons whose statements if not altogether untrustworthy were usually not strictly accurate. There was conflict not only between the witnesses but between their statements, and the whole evidence was a mere morass and not to be accepted with any degree of confidence. On the other hand, they had the testimony of a higher class of witnesses who, moreover, had subjected themselves to cross-examination. The collectors' evidence had exonerated themselves and the organisation for which they acted, and he therefore claimed that the alleged systematic canvassing for medical patients had not taken place. As to Dr. Rendall's approval or acquiescence in such canvassing, that gentleman's evidence was dead against that. He therefore asked that the Council should come to the conclusion that the case had not been established, and in dismissing it to leave all the societies of a nature kindred to the Victoria and the National Medical Aid Company to continue to carry on their operations providing the authorities conducting them set their faces against canvassing for medical men. He was authorised to say that if the Council thought that the wage-limit at Yarmouth was not sufficiently rigid his clients were willing to adopt any new limit laid down in order that their operations might be confined to those people who were so poor that they would never employ any medical man of their own. Further, that as it would not be worth while to keep up a separate staff for the medical society which could only be worked through the Victoria Society his clients wished him to say that it would be better to let the medical society die out than to have a separate staff for it.

Dr. BATEMAN contended that the case had been proved absolutely in all its aspects. He admitted that it was a picked case, but it was picked because it embodied most of the objectionable characteristics that were involved in medical aid associations. The Medical Defence Union was determined to do its level best to stop advertising of medical men through these associations and it did not care how many thousands were involved and would not be frightened by their number. The profession were watching this particular case very carefully and he hoped that any decision the Council came to would be for the benefit of the profession.

The Council deliberated on the case *in camera*. On the parties being recalled the decision was announced.

The PRESIDENT, addressing Dr. Rendall, said: The Council have deliberated very carefully on your case, and they have come to the conclusion that the facts alleged against you in the notice of inquiry have been proved to the satisfaction of the Council. They have instructed me to

say to you that they feel it their duty to express their sense of the gravity of the facts which have been proved against you; but in order to give you an opportunity seriously to reconsider your position in relation to the Liverpool Victoria Legal Friendly Society and the National Medical Aid Company, Limited, they have adjourned the further consideration of the charge until the next session, when you will have to appear and to satisfy the Council as to your conduct in the interval.

The Council adjourned.

SATURDAY, NOV. 30TH.

The Council resumed, Sir WILLIAM TURNER, President, being in the chair.

#### *The Standard of Preliminary Examinations.*

The debate on the report of the Education Committee with reference to the steps taken for the improvement of preliminary examinations was resumed.

Dr. PAYNE expressed the view that it would be a mark of partiality if they made the exception proposed by Dr. Norman Moore in his amendment in the case of the University of London.

Dr. MACALISTER pointed out that if there were any case of hardship it could be dealt with by the Students' Registration Committee.

Dr. WINDLE congratulated the Education Committee on the work which it had accomplished. He was a member of the committee which advised the Board of Education on secondary education and he could assure the Council that he and his colleagues attached a very high value to the report of the Education Committee. They often heard in the medical papers loud cries to that Council to raise the standard of preliminary education. Now, he wished to point out that any person who had carefully studied the matters relating to secondary education must perceive that it was perfectly impossible for that or any other body suddenly to raise the standard of preliminary education. No body could, without producing a dangerous dislocation in educational matters, go too far in advance of the schools, and at the present time he thought they had brought their standard up quite as high as the standard of education in the schools of this country would bear. If they were to attempt to do anything further they would produce a sudden decrease in the number of persons passing the preliminary examination for medical education, which he thought would have a serious effect upon the necessary output of medical men for the service of the country. What the Council could do, and what, it appeared to him, the policy of the Education Committee had been, was gradually to endeavour to screw up the standard and to draw with them the teachers in the schools. That was a policy which would certainly succeed; the other was one which must inevitably fail, and he hoped that no pressure from the outside would lead the Education Committee to attempt to take any very sudden step in the matter or to pursue any other course than that they had pursued. In his opinion, the secondary education of the country as a whole required a stimulus of exactly the character which had been imparted to it by the Education Committee.

Dr. PYE-SMITH said that he was not aware that the University of London asked for the exceptional treatment which Dr. Norman Moore proposed for it. This examination was used partly as an introduction to further study and partly as a leaving examination for schools, and its future was now under consideration. The two classes of candidates were so different that the Senate of the University was at the present moment considering whether it would not be better to have two examinations, one for internal and the other for external students. He did not think that there would be the least difficulty in bringing the examination into harmony with the regulations laid down in this report.

In view of the statement of Dr. MacAlister Dr. NORMAN MOORE agreed to withdraw his amendment.

The debate therefore proceeded on the motion for the adoption of the report.

Sir CHRISTOPHER NIXON said that the object of the report was mainly to effect a uniform standard of preliminary training, and in order to secure that it was necessary that the regulations should apply to every university and licensing body throughout the kingdom. The body which declined to

conform with the regulations was the Conjoint Examining Board in England, which stated that it would only accept the examinations of institutions recognised by itself. What would that lead to? Had that Council any guarantee that this body would adhere even to the present arrangement? There was talk about an understanding that the Conjoint Board would only recognise the examinations recognised by the Council, but there was no official communication on the subject. It would not be fair to the other bodies if that Council refrained from asserting its authority, if it had any authority in this matter. He contrasted with the action of the English Royal Colleges the action of the Irish Royal Colleges when the Council recommended that the examination of the latter should be discontinued. They did not write back to say that the Council had no power in the matter, and that they took their stand on their ancient charters and privileges. The Irish colleges had quite as many charters as the Royal College of Physicians of London. They had two or three from William and Mary and several others. They had exactly the same rights as the English Colleges, and they were determined to exercise those rights, but not in antagonism to the work which that Council were doing to raise the status of the profession and the character of medical education. They put themselves in communication with the University of Dublin and the Royal University and the Intermediate Board, and when they found that these bodies could not help them they reorganised their own board and improved the system of examination, and when they presented an account of what they had done the examination was continued. Were the Irish representatives to go home and say that that Council had one rule for Colleges in Ireland—a very drastic rule, that they must conform to the regulations or their examinations would be struck off the list—and quite another rule for Colleges in England? He assured the Council that unless they were prepared to deal with this matter in a uniform spirit of fairness he would tell his College and the Royal University with which he happened to be connected that that Council were not disposed to act with uniformity towards the universities and corporations throughout the kingdom, and that they were not necessarily obliged to adhere to, or follow, any of their recommendations. That was the situation. For their own dignity that Council should have their position defined. If they had not the power let them get the power; if they had the power let them exercise it.

Mr. BRYANT said that while the English Colleges adhered to their rights they had been strictly loyal to that Council. It was at his instance that there had been an inquiry made as to the value of the special examination held by the College of Preceptors. With regard to these preliminary examinations they had accepted all the recommendations of the Council and no one had any right to suggest that they meant to do otherwise than work with the Council in the future as they had done in the past. They had been loyal in the past and they would be loyal in the future.

Dr. NORMAN MOORE assured the Council that his College had nothing but the profoundest respect for every body represented there. He would not enter into the question whether William and Mary, from whom the Irish College got their Charter, or Henry VIII., who lived a little earlier, from whom the English College obtained theirs was most mischievous to the human race. His College based their case upon its justice as considered at the present day. Rights such as theirs were in the strictest sense a trust and it was of the essence of every trust that the people holding it should be rendered accountable and they were perfectly ready to be rendered accountable. They considered that they had a trust for the public, and that was the way in which they looked upon their duties. When a trust was imposed upon a man he was bound to give it up to nobody else but to discharge it according to his conscience, and that was what his College had endeavoured to do. It had been said that they acted independently of the Council, and it had been tried to be made out that they were endeavouring to put themselves in a different position from every other body. Anything that that Council recommended was carried out by the bodies of their own act. The Council said so and so and the body considered it and adopted it; that was the procedure. They were all independent bodies. If the statute had given the Council power to command a thing to be done then the bodies would not be in that position. It was in the highest degree desirable that they should all agree to some things and the

subject of preliminary education was one of them. The English Colleges were alive to the fact that it was desirable that all the qualifying bodies should agree to this, and they themselves had agreed to it. It was open to any person to apply to the Conjoint Board for the list of examinations recognised by the two Colleges, and they would find that it was absolutely identical with that of the Council. But, said Sir Christopher Nixon, what security had they for this. They had no security except the character of the Colleges. Had they in the past endeavoured to do everything for their own private interest and nothing for medical education? Had not exactly the contrary been their career? That was the only security they could have and no other security ought to be given.

Dr. PETTIGREW insisted that this was the parting of the ways, and that if the English Colleges were allowed to do this thing their example would be followed by other bodies.

Dr. GLOVER, speaking as one who would soon cease to be a member of the Council, said that he greatly regretted the tendency to the creation of questions which required annual attention and annual discussion, and he hoped this question would soon pass from that category. He thought they should try to bring to a point the different elements in the question. For one thing, he would like to know why one conjoint body, like that of the English Colleges, should be so entirely dissociated from other bodies which were practically in the same position. Sir Christopher Nixon said if they had not the powers let the Council get them, and if they had the powers let them use them. Would Sir Christopher Nixon tell them when they were likely to get the powers? He thought it unwise to speak as Sir Christopher Nixon had done. His opinion was that the Council should make the best use of the powers they already possessed. There was no prospect within the life-time of any member sitting at that table of seeing the Council endowed with such powers as Sir Christopher Nixon desiderated. It had been the constant practice and pride of that Council to refer to the authorities of the individual bodies and it had been the policy of the Council not to interfere with them but to leave as much as possible intact the individual responsibility and authority and functions and dignity of these bodies. He held that they would not get the legislation Sir Christopher Nixon referred to and he further held that if that Council went to the Privy Council to ask it to adjudicate between itself and the Colleges the former would come to terrible grief. He would quote to the Council the words of one of its distinguished members, Sir James Paget, who said: "I hold that our great anxiety, our great strife, should be to be a self-governed profession, to know our own wants and not to go to others to help us, to find out the remedies for ourselves, to find out by careful, patient controversy and mutual concessions how we may without any external help bring about the results which the best and the largest number of us wish for. Let us be, as all highly cultivated persons should be, self-governed. It tells of feebleness, of cowardice, and want of self-reliance when we want to go to any Parliament living to help us." He wanted to know what the English Colleges had done that they should be treated with such criticism and suspicion as they had been treated with in the course of these debates. Would the Irish Colleges, who had been so much in evidence in debate, say that the English Colleges were a refuge for illiterate or incompetent students? He had never heard that said, and there was no evidence of anything of the kind. Was there anything in the proceedings or minutes of that Council to show that there was any defect in the science teaching of the candidates of the English Colleges? In fact, was there anything to justify this persistent attack upon the English Colleges for asserting their own functions and independence as other bodies had done? He should like to hear these questions answered.

Mr. BALL wished to point out that the Royal College of Surgeons in Ireland had made no pronouncement on the subject before the Council, but when discussion arose on other business on the programme he would crave liberty to answer what Dr. Glover had said.

Dr. ATTHILL suggested that the question had now been discussed very largely and it would be raised again on Monday or Tuesday, and therefore he thought consideration of it should end for that day. He moved the closure.

The PRESIDENT reminded the Council that on a previous occasion when he at once put to the vote a motion for the closure representation had been made to him that he might first have afforded the mover an opportunity to reply.

Perhaps, therefore, before proceeding to a vote now Sir John Batty Tukey should be allowed to reply if he had anything to say.

Sir JOHN BATTY TUKE wished to say only a few words. He made no apology for having made the remarks he did when presenting the report, for he thought they had led to a very important debate and brought out important information from the representatives of the two Colleges. He inferred from what Dr. Norman Moore and Mr. Bryant had said that they gave a promise or undertaking that the Royal Colleges would not go outside the list of qualifying bodies which the Education Committee had laid before the Council. He wished to ask Dr. Norman Moore if that was not right.

Dr. NORMAN MOORE: The question is hardly a question to be put in that sort of way and I decline to answer.

Sir JOHN BATTY TUKE: I do not ask for an answer. I infer that, rightly or wrongly, from the statement of these two gentlemen; but the main difficulty is that the Royal Colleges demand for themselves an examination in general education recognised by the Examining Board for England. The same action would be open to any other body, and it would be absolutely impossible for the General Medical Council or its committees to maintain a standard of examination if other bodies took the same line.

The motion for the closure having then been carried,

The report was unanimously agreed to.

#### *Prevention of Personation.*

The Council proceeded to the consideration of the proposed regulations for the prevention of personation.

Mr. HORSLEY, as chairman of the Personation Committee, explained that the regulations to be now brought forward formed part of a general scheme which had been discussed by the Council in previous sessions. He moved that they should go into committee and consider the proposals one by one.

This motion was agreed to.

Mr. HORSLEY moved the adoption of the following proposed regulation:—

1. No registration on the Students' Medical, or Dental Register respectively shall be effected unless application has been made for that purpose on one of the forms included in the accompanying schedule.

The PRESIDENT asked how far the forms in the schedule were altered.

Mr. HORSLEY replied that they were altered to this extent, that they contained a provision that the person applying for registration must fill up the form in his own handwriting.

Dr. WINDLE remarked that the schedule would in no way prove that the person presenting a pass certificate to the registrar was the same person who passed the examination. That, he said, was a most important point, as it was within his own knowledge that a "coach" had been up and passed the examination for his pupil, which he thought was quite an easy way of getting through. He of course excluded university examinations, because a pupil who passed one of these was afterwards seen at the classes. However, it was possible to have an examination conducted outside of the universities passed apparently without detection, and what he should like to see would be the adoption of some means by which a body whose examination had been passed might have an opportunity of comparing the handwriting of the examination papers and that of the person who had filled in the form of application.

Dr. MACALISTER said that that would be a very desirable thing to secure if it could be secured, but it was practically impossible that it could be. The papers that a candidate took and wrote himself for his examination were not preserved, and it would be practically impossible to send back an application form where he might have been examined years and years before and ask somebody to compare the handwriting. He agreed that personation was a fact at these preliminary examinations, and mentioned that one actual case of the kind had come before the Students' Registration Committee during the present session. So far as the form Mr. Horsley wished them now to adopt was concerned it was neither the form that was in existence now nor was it in accordance with the law.

The PRESIDENT pointed out that these regulations were to have been considered in consultation with the registrars—Mr. Allen their own registrar, and the registrars of the Branch Councils of Scotland and Ireland.

Mr. HORSLEY: Oh, yes, and there is nothing new. The schedule will have to be altered in several particulars.

Dr. MACALISTER: Quite so; made a different schedule.

Mr. HORSLEY: The alterations in Form 1 are verbal, but we can get the form corrected and brought up to date, and in its amended shape it can be brought up with the report of the committee.

The words "as revised to date" were added after "schedule," and the proposed regulation in this amended form was agreed to.

Mr. HORSLEY said that the next proposed regulation was simply a statement of what was the custom at the present time. It was purely formal and was as follows:—

II. All forms of application for registration, duly signed and presented, shall be bound, indexed, and preserved by the Registrar of the Branch Council to whom they may be presented.

On being seconded by Dr. REID this regulation was at once adopted.

Mr. HORSLEY next moved:—

III. No certificates of registration of any name on the Medical or Dental Register shall be given except a letter in the Form 8 of the accompanying schedule.

He explained that the present practice was to issue certificates of registration. The committee thought there was great danger attached to this system. The registrar held that if any person presented himself and asked for a certificate of registration, at the same time paying the fee, he was obliged to give a certificate stating that such-and-such a person was registered. It was a fact that the Council had never authorised the issue of such certificates, and it was equally a fact that certificates had been obtained and used for personating purposes. To meet the case the committee proposed that a letter in the following terms should be granted by the registrar in substitution of a certificate on request:—

General Medical Council, 299, Oxford-street, W.

DEAR SIR, I hereby certify that the following ——— is a true and correct copy in the (Medical or Dental) Register of the current date, and that this certificate is only valid until the next annual issue of the Register.—I have the honour to be, yours very obediently,

Registrar of General Medical Council.

Anyone producing such a paper as that could not hand it out as a diploma or anything of that sort, and the committee thought the registrar should only write such a letter upon an immediate request. They believed that the danger of personation would in a great measure be avoided if their suggestion were adopted. Some receipt should be given for the £5 handed over the counter, but the committee agreed that it should be a receipt in ordinary terms, not one in the form of a certificate.

Dr. REID seconded the motion.

The PRESIDENT asked if they were to understand that when a person applied for registration as a practitioner, and paid his £5, the only evidence that he had been put upon the manuscript Register was a receipt stating that he had paid £5.

Mr. HORSLEY: No; if he required evidence of registration he would ask for a letter and the registrar would fill up the letter in the proposed form.

The PRESIDENT: A man who comes for registration has a right to ask under the Act for a certificate, and, what is more, we have no right to refuse it. I do not see how we can get past that. Every registered practitioner should have some evidence that he is registered. For instance, when a young practitioner is challenged, say, in the witness-box he ought to have evidence in his pocket and not be required to write to the registrar for it.

Mr. HORSLEY: The feeling of the committee was that young practitioners ought not to have this evidence in the pocket, for the young practitioner very often loses his certificate.

The PRESIDENT: But this certificate is only a temporary one; it is only necessary until the following year when the name appears on the Register.

Dr. MACALISTER said that the certificates now issued were certificates for a life-time. An applicant should get a certificate when he first registered and he should preserve it. To give a letter such as proposed would only multiply labour and do no good.

Sir CHRISTOPHER NIXON supported the view that a man on first registration should get a certificate.

Further discussion of the proposed regulation was interrupted at four o'clock—the usual hour for the termination of the Saturday sitting.

The Council thereupon resumed, and immediately adjourned till Monday.

MONDAY, DEC. 2ND.

The Council resumed work, Sir WILLIAM TURNER presiding.

Mr. George Brown and the Chair—*Electioneering Literature.*

The first business was the consideration of the following letter addressed to the President—viz.:

6, Gibson-square, London, N.,  
November 30th, 1901.

DEAR SIR WM. TURNER.—I beg to call your attention to the annexed cutting from the *British Medical Journal* of to-day's date, headed "The Gallery of the Council Chamber," from which I learn that, during the time I have had the honour of occupying a seat in the Council chamber, I have been flouted by you from the Presidential chair.

It may be due to my obtuseness but I have no recollection of having at any time been treated by you in a manner which would justify such a description.

I scarcely need say that if this description of your conduct as our President is allowed to pass unchallenged it must tend to lower the Council in public estimation, and I propose, therefore, at our next sitting, after the reading of the minutes, to ask you to make a public statement as to whether the paragraph in question correctly represents your attitude towards me.

I remain, yours faithfully,

(Signed) GEORGE BROWN.

"THE GALLERY OF THE COUNCIL CHAMBER."

"SIR.—Mr. Horsley could not give Mr. George Brown a better testimonial than to say he has been 'shouted down' in the Council chamber and 'flouted' by the President. This proves that Mr. Brown has done his duty without 'fear or favour,' and the electors, I have no doubt, will reward him by returning him and Mr. Jackson by a thumping majority. At the same time I am quite prepared to accept Mr. Horsley's statement without going in person to witness such a disgraceful and unedifying spectacle. If the profession is only true to itself in this election 'midwife registration' will receive its quietus, and its advocates a most salutary lesson. The issue is clear, and the best advice on the eve of the election is to vote, vote, vote for Brown and Jackson."

"I am, &c."

"Liverpool, November 23."

"ALEX. MCCOOK WEIR."

The PRESIDENT suggested that in the first place an opportunity should be given to Mr. Horsley of saying whether the words and expressions marked by inverted commas were a correct representation of what he had said.

Mr. HORSLEY said that he should have thought that the first step in this matter would have been for the President on the receipt of Mr. Brown's letter to have communicated the contents to him (Mr. Horsley) and asked him whether Dr. Weir's letter was a correct statement or not of what he had said. The whole of this incident was nothing but a squalid electioneering device and he could show that this letter of Dr. Weir's was nothing but a literary forgery and yet it appeared on the programme of business of that Council. He did not think therefore that the matter had been dealt with quite in the proper way. He made a speech at Liverpool in which he drew attention chiefly to the methods of the Direct Representatives in this chamber and the way in which those methods reacted unfavourably upon direct representation and upon the conduct of business and how those methods brought down the condemnation of the chair. As he could not obviously refer to any of the Direct Representatives in person he was obliged also to refer to his own experience, to mix the two together, in fact; but in order that there should be no doubt as to what he meant he made his statements entirely in support of one fact, or what he wished to be a fact—namely, the return of a general practitioner to that Council who should worthily represent the practitioners, who should not, as he stated and as would be found in one report of his speech, excite derision and contempt on the part of members of that Council.

The PRESIDENT: I am sorry, of course, to interrupt, but the question I put to you was whether those words and expressions correctly represent what you said?

Mr. HORSLEY: I am about to say that they do not. I am stating to the Council what I did say. I thought that was the best way of beginning the business. If you think I have said enough I shall be quite ready to stop.

The PRESIDENT: No; because you have not answered the question.

Mr. HORSLEY: I am going on to answer the question, but you must lay a foundation first. That was his line of argument. Now, if they looked at the letter they would see that it was stated he said Mr. Brown had been shouted down in this chamber, and the words "shouted down" were in inverted commas. He never used those words. Then there was the expression "flouted by the President." He never used those words. Then the letter went on to say, "This proves that Mr. Brown has done his duty without fear or favour," and that Mr. Brown had been attacked by the

President in an unwarrantable manner in that Council and without any justification, and that that constituted a reason for returning him at the election. That was not what he (Mr. Horsley) stated. On the contrary, the whole tenour of his remarks were directed in absolutely the opposite direction, so that this letter was not only a falsification of words but a total falsification of his meaning, and if the President had addressed him on Saturday he could have shown him that that was not the first time that this speech of his had been falsified by Dr. McCook Weir. This was really the second edition of this forgery, if he might so describe it.

The PRESIDENT: We have nothing to do with Dr. McCook Weir.

Mr. HORSLEY: I thought you asked me to prove—

The PRESIDENT: The question I put to you was this, Did the words and expressions marked by inverted commas correctly represent what you said?

Mr. HORSLEY: No, they do not.

Mr. GEORGE BROWN asked leave to say a few words. He would be very brief and he would avoid the personal. It was only on Sunday morning that he had had an opportunity of reading this previous letter. For himself he should take no notice of an election speech, but when he found that the conduct of the President in the chair was called in question he thought it his duty to direct attention to the matter and therefore he wrote the letter which appeared on the programme of business. He was asked yesterday by a member of the Council if he could tell whether Mr. Horsley had said anything of the kind and he said that he did not know, he had no time to read Mr. Horsley's speeches. Having been 30 years before the medical profession in regard to medical reform and medical ethics he was very well content to leave his professional and public career to the judgment of that profession. But he said to the member of the Council that he would look up the files of the *British Medical Journal*.

Mr. HORSLEY, rising to a point of order, said that if Mr. Brown was going to read a report of his speech at Liverpool and to comment upon it he submitted that the Council should have notice and that the whole of the speech should be printed in order that members might see what he said. He was prepared to substantiate every word of that speech.

The PRESIDENT said that he thought Mr. Brown should just allow him to answer the question which had been put to him.

Mr. BROWN: Very well, I will leave the matter. I am only concerned about the Council and our President.

The PRESIDENT: I am answering this question, having clearly before me that Mr. Horsley has himself stated definitely that he did not use these expressions, and therefore it will be also understood that my answer does not apply to him because he disclaims having used the expressions.

Mr. HORSLEY: Not only the expressions but also the application of the expressions, which is far more important than the actual words, because I may have used words something like these.

The PRESIDENT: This is what I have put down in writing: "The President stated on his own behalf and on that of the Council, that the words and expressions referred to do not correctly represent his attitude towards Mr. George Brown in this Council and that such words and expressions are a complete misuse of the English language as regards any proceedings in the Council." That is the answer which I intend to put on the minutes of the proceedings.

The incident then closed.

#### *Prevention of Personation.*

Instead of proceeding with the further consideration of the report of the committee on this subject, the Council decided, on the motion of Dr. BRUCE, to refer the report back to the committee, together with the proposed regulations, with a view of obtaining detailed comments by the Branch registrars of England, Scotland, and Ireland. Dr. Bruce took the view that the matter was not yet ripe for decision. The names of Dr. Windle and Sir Christopher Nixon were added to the committee and Dr. Reid agreed to take the place of Sir John Batty Tuke who asked to be relieved from service.

#### *Medical Practitioners and the Sale of Poisons.*

Dr. MACALISTER moved:

That the following notice be issued by the Council for the information of registered medical practitioners:

Whereas it has been made to appear to the General Medical Council

that certain registered medical practitioners, who keep medical halls or open shops for the sale to the public of scheduled poisons and other drugs, have been accustomed to leave in charge of such halls or shops assistants who are not legally qualified to sell scheduled poisons to the public; and that such practitioners have thereby, for their own profit and under cover of their medical qualifications, enabled such unqualified assistants to sell scheduled poisons and so to commit breaches of the law; and whereas, in the opinion of the Council, such practices on the part of a registered medical practitioner are professionally discreditable and fraught with danger to the public, the Council hereby gives notice that any registered medical practitioner who is proved to have so offended is liable to be judged as guilty of "infamous conduct in a professional respect," and to have his name erased from the Medical Register under the 29th Section of the Medical Act, 1858.

He explained that that notice had been drawn up with the assistance of the legal advisers and followed very closely the lines of the notice with regard to covering. He thought it was more perhaps than usually desirable to issue a precise description of the particular offence which had come under their notice and which they had had to deal with judicially because some misunderstanding had obviously taken place among practitioners in a certain part of the kingdom as to the precise nature of what they had regarded as an offence.

Dr. BRUCE suggested that the words "for the sale to the public of scheduled poisons and other drugs" should be omitted as they made an offence of what was perfectly legal.

Mr. BALL thought that in place of these words they might insert "in which scheduled poisons are sold to the public."

This change commended itself to the Council and was adopted.

Dr. MCVAIL asked whether the notice would apply to the dispensing of scheduled poisons in a dispensary in a practitioner's house.

Dr. MACALISTER replied that the notice was confined to the class of cases of which the Council had had recent experience—namely, to open shops.

Dr. HERON WATSON thought that the Council should make it clear whether the notice extended to "preparations containing scheduled poisons."

Dr. MACALISTER said that the courts had decided that point.

Dr. HERON WATSON: But this is for the information of medical practitioners.

After some discussion the Council agreed to accept the words mentioned by Dr. Heron Watson.

Mr. A. H. YOUNG: Does "open surgery" mean the same as "open shop"?

Dr. MACALISTER: A man may call the place what he likes; the offence is leaving in charge of such a place where scheduled poisons can be sold a person not qualified to sell them.

The notice altered so as to read "who keep medical halls or open shops in which scheduled poisons or preparations containing scheduled poisons are sold to the public," &c., was then approved by the Council and ordered to be published.

#### *The Period of Professional Study.*

The Council proceeded to receive the following report from the Education Committee on the motion and amendment with regard to the conditions for admission to the Medical Students' Register, referred to them on June 10th, 1901, arising out of the consideration of certain communications from the Royal College of Physicians of London and the Royal College of Surgeons of England.

The Education Committee have considered the following motions by Dr. Bruce and Mr. Ball, which were referred to them on June 10th, 1901, by the following resolution of the Council: "That the Council, instead of expressing an opinion on the principles involved in the motion proposed by Dr. Bruce and the amendment proposed by Mr. Ball refers them to the Education Committee for consideration and report to the Council."

Dr. Bruce's motion: "That it be referred to the Education Committee to consider and report to the Council whether it is desirable and practicable to provide (1) that students shall be required to pass a recognised examination in the subjects of physics, chemistry, and biology subsequently to passing a recognised examination in the subjects of preliminary education; (2) that a second or preliminary scientific registration of students who have thus passed in chemistry, physics, and biology be established by the Council; and (3) that, dating from this second or preliminary scientific registration, the period of professional medical study be four years."

Mr. Ball's amendment: "That it be referred to the Education Committee to consider and report to the Council whether it is desirable and practicable to provide (1) that, after a date to be named, preliminary examination for admission to the medical profession shall consist of two sections:—Section (A).—An examination in general education as at present authorised by the General Medical Council, Section (B).—An examination in physics, biology, and chemistry conducted by any recognised licensing body. (2) That no person be

admitted to register as a medical student with the Registrar of the General Medical Council who has not passed both the above sections of the preliminary examination, and has not produced evidence of entry at a recognised medical school. (3) That no person receive any diploma until after the expiration of four winter and four summer sessions from the date of registration."

The principles involved in these proposals appear to the committee to be:—1. That for complete registration a medical student should fulfil three conditions: (a) He must have passed a recognised "arts" examination, as at present; (b) he must have passed a recognised "preliminary science" examination, such as at present usually concludes the first year of the curriculum; and (c) he must have begun professional study at a medical school. 2. That the minimum period of professional study after such complete registration should be four academic years.

While it may be maintained that a system of registration established on these lines would possess certain advantages, it is clear to the committee that it could not come into effect without the approval and cooperation of the several licensing bodies. In the case of a number of these the change from the present system would involve important alterations in their statutes and by-laws, and in some instances the bodies would be unable to make such alterations by their own action alone.

The committee therefore feel that they are not in a position, without further inquiry and consideration, to determine whether the suggested changes are practicable; and they are of opinion that the Council should not at present commit itself to either of the two proposals which have been submitted.

The committee are not unanimous as to the expediency of the Council's taking any action at present in the direction suggested. They have, however, agreed to submit the following propositions for the decision of the Council, and they are willing, should the Council adopt these, to undertake the necessary inquiries on the Council's behalf:—1. That the Council approves of the suggestion that the registration of a medical student should be postponed until he has passed a recognised examination in the preliminary scientific subjects, on the understanding that the subsequent course of professional study should occupy at least four academic years. 2. That the Council instructs the Education Committee to communicate the foregoing resolution to the licensing bodies and to inquire on behalf of the Council whether the change therein suggested is considered by them to be desirable and practicable.

JOHN BATTY TUKE, Chairman.

Nov. 28, 1901.

On the motion of Sir JOHN BATTY TUKE, seconded by Dr. BRUCE, the foregoing report was received and entered on the minutes.

Sir JOHN BATTY TUKE moved that the report be now considered.

This proposal was seconded by Dr. BENNETT.

Dr. WINDLE moved as an amendment that the following proposal, standing on the programme in the names of Dr. McVail and Mr. Young, be first dealt with, viz:—

That a committee be appointed to prepare a report on the differences that exist between certain licensing bodies on the one hand and the General Medical Council on the other regarding the courses and conditions of study and the recognition of the institutions and schools in which the required courses may be taken, and that the report be considered by the Medical Council at a special meeting, when the Council will decide what action, if any, shall be taken, and in particular whether the circumstances are such as to require action to be taken under Section 20 of the Act of 1858.

It was perfectly obvious, Dr. Windle said, that this motion raised the whole question involved in the Education Committee's report and, in his opinion, in a more convenient form than in the report.

Dr. REID seconded the amendment.

Mr. BALL opposed the amendment on the ground that if Dr. McVail's proposal was taken first and was carried it would dispose of the matter altogether and there would be no opportunity to discuss the report.

Dr. ATTHILL also opposed the amendment. He objected to any step being taken which would leave the matter involved in uncertainty for a third year. Nothing could be so unfortunate as a further postponement. There was a feeling of the greatest irritation on the part of the licensing bodies of Ireland at the repeated postponement of the question, and if something definite was not done this session it would cause a great deal of trouble.

Sir JOHN BATTY TUKE felt himself to be in a very difficult position at the moment, for he thought that it would be much better to proceed first with Dr. McVail's motion as that would settle the whole matter.

Sir WILLIAM THOMSON hoped that the order of business as on the programme would be adhered to.

Dr. McVAIL said that Mr. Young and he had no wish to press their motion on the Council unduly. The motion, however, could be discussed in a very short time, but what might take place if the report were discussed might not tend towards peace.

On a vote being taken the amendment was defeated by 14 to 7, and it was agreed to proceed with the consideration of the report. A proposal by Dr. ATTHILL that it be taken in committee of the whole Council was rejected.

Sir JOHN BATTY TUKE then stated that the motion by

Dr. Bruce and the amendment by Mr. Ball, which were embodied in the report, had been under the very careful consideration of the committee on two occasions during the past week. They had been considered in the best spirit and without anything like warmth. But there was such divergence of opinion that it was utterly hopeless for the committee to come to what might be properly called a report. His own feelings on the matter did not allow him to move the first of the recommendations at the end of the report, and he thought it was arranged by the committee that Sir Christopher Nixon should move the adoption of that recommendation.

Mr. HORSLEY did not understand this sort of procedure.

Sir CHRISTOPHER NIXON, in moving the adoption of the recommendation, said that what they wanted to do was to affirm the principle that it would be desirable to establish a preliminary scientific examination; that it would be desirable to postpone the registration of students until that preliminary scientific examination was passed, and that the period of the curriculum from the date of registration should be four years, these to be devoted strictly to medical study. This proposition was put forward to elicit from the Council an opinion as to whether it was desirable to make what was a very radical change in the present system. In supporting his motion he desired to keep two things apart—the first, the question as to the conditions in regard to the preliminary subjects and the length of the medical curriculum; and the second, the question as to where the preliminary scientific subjects should be studied. The first point which he desired to emphasise was that the subjects they put down for the first year of medical education were not medical subjects at all. They were subjects of general culture, and it was only by a high stretch of imagination that physics could be called medical physics, that chemistry as taught in the universities and institutions recognised by the Council was medical chemistry, and that botany and zoology could be so sufficiently specialised as to make them medical studies at all. He argued that these subjects were subjects of general education, subjects to insure that the student had broad general culture. What he put to the Council was that when they were raising the standard of preliminary education they ought to look upon that standard as having two sides—the arts side and the scientific; and if they added to the arts requirements the amount of science training which they now required from the student as his first year of study they would have students with such a broad degree of culture that when they came to medicine they would be capable of taking a proper view of the subject. Let them bear in mind that the Council had been treating these subjects not as medical subjects, but had been recognising that the examinations in the universities and the course of instruction in the universities were in connexion with arts and science and not in connexion with medical training. It did not mean that these subjects should be specialised as medical subjects at all. They recognised certain high-class institutions that had no lectures in connexion with medicine; so the Council had affirmed the proposition that these subjects were not medical subjects at all. In his view the student should be free and unfettered when he commenced his four years' medical studies. Of course, if the Council adopted what he was urging they would have to make a very considerable modification in the medical curriculum. The present arrangement of subjects was a bad one for the student. The suggestion of dissociating the preliminary scientific subjects was by no means new. In 1881, when there was a four years' course the Council had passed a resolution in the same direction as this motion went, and curiously enough the different examining boards when questioned agreed with the Council. There was far greater reason for introducing a preliminary scientific examination with the five years' course in existence than there was when the course was only four years. It was a hardship on medical students to prolong the study beyond five years, and on behalf of them the Council ought to secure that the five years were spent most advantageously, and he believed that it would be most advantageous to the student if the year prior to medical subjects proper was devoted to the preliminary scientific studies. As to what institutions should be recognised as giving instruction in these preliminary scientific subjects, he took it that this was a question which more concerned the licensing corporations than the universities. He supposed that the universities would require the higher form of

education, with lecturers and full equipment, but he did not think that that was at all necessary for students presenting themselves to the corporations. This was the point which had really raised the contention between the English Royal Colleges and the Council, and he must say that he thought the Royal Colleges were in the right. He did not wish to imply that in the matter of dealing with the General Medical Council the Royal Colleges were in the right. That was not a question he need enter upon now, but what he argued was this, that once the Council recognised certain scientific institutions in which training in the preliminary medical subjects might be taken it gave away the whole case, because it drew the distinction between the education given in medical schools—where men must take set courses in physics, chemistry, and biology—and institutions in which the preliminary subjects were taught. When that distinction was drawn he thought the Council should be satisfied with the high standard of the examination conducted by the licensing bodies and not take very much trouble as to where the training was got. Members were not, he thought, at that Council to consider vested interests. Their first duty was to raise the status of the medical profession and to secure that the men on their Register were men of the culture that medical practitioners ought to possess. They had nothing to do with the arrangements which existed in the schools. What they had to do was to see that the men secured such an education as would enable them to pass a strict examination. In conclusion, he expressed the hope that the representatives of the two English Royal Colleges would support the principle he had ventured to urge upon the Council, and he asked leave to put the proposal in the following form:—

That the Council approve of the suggestion that the registration of a medical student should be postponed until he has passed (1) a recognised examination in arts and (2) a recognised examination conducted by the qualifying bodies in the preliminary scientific subjects, on the understanding that the subsequent course of professional study should occupy at least four academic years.

Dr. BRUCE seconded the motion.

Dr. PETTIGREW strongly opposed the adoption of the recommendation. He thought that it was in order to make room for chemistry, physics, and biology that the five years' curriculum had been instituted, and the Council at the time had been quite unanimous in including the three subjects in the medical course, and so were the licensing bodies. All "rights" had been waived in order to secure what might be best for the students and best for the profession, and if Sir Christopher Nixon's motion was carried they would be taking a step backwards. He hoped that the three subjects would not be taken out of the medical course. They were very valuable as part of it; indeed, more valuable in these advanced days than they were when the five years' curriculum was adopted. They formed, as it were, a link between the arts examination and the medical course, and nothing would be gained by striking them out of the latter. Things were going on very well. His fear was that if they once began tinkering with the curriculum they would be plunged into indefinite confusion. The licensing bodies would not know where they were, and there would be no end of trouble.

Dr. BENNETT informed the Council that a few days ago the Executive Committee of Trinity College, Dublin, whose members with one exception were laymen, passed a resolution declaring that in consequence of the position taken by the English Royal Colleges regarding the first year's subjects it was to be clearly understood that the University of Dublin held itself free to deal with the five years' curriculum as it might consider best to further the interests of its students and medical education in Ireland. He was instructed to say that the proposal before the Council would operate against the medical status in Ireland—that it was a retrograde step.

Mr. BALL said that in his opening address the President had expressed the hope "that both the Education Committee and the Council will bear in mind the paramount importance of the Council not losing its hold on the standard of general education to be required from students of medicine." That was a sentiment which every member of the Council endorsed, and it was in accordance with it that he had last session proposed his amendment. If that were adopted in the form embodied in Sir Christopher Nixon's motion—adopted by the Council and accepted by the licensing bodies—it would place the preliminary scientific subjects on a similar plane to those of general education, and with a four years' medical course proper they would be

spared the melancholy spectacle of men trying to get on with the medical course and being repeatedly rejected in the three preliminary scientific subjects. The adoption of the preliminary scientific examination would, he believed, induce many good men to go into the profession who otherwise would not. Many men went to the universities without any definite intention to take the medical course. When there, however, they become enamoured of the subject, and having obtained a sound knowledge of the three subjects in question they desired to enter upon the medical course. What were they to do? At present they had five years' study to face, but if the proposition now before the Council were adopted they, having already passed the three subjects in their arts course, would start with only four years' professional work before them. He would ask those who did not agree with the proposal what alternative they proposed to get the Council out of the difficulty they were in. There could not be any doubt that the example set by Dublin University would be followed before long by other licensing bodies, and he would urge them, therefore, to consider whether they could not give their approval to Sir Christopher Nixon's motion so as to secure a uniform four years' course of professional study.

Dr. PAYNE reminded the Council that in 1899, on the first occasion that he spoke on the subject, he suggested that the best *modus vivendi* between the Council and the two Royal Colleges would be to adopt the system which was now suggested to the Council, and which he would give his support to. The resolution did not say how or where the scientific education was to be given, and the only real danger was that the scientific education might be got when the candidate was too young.

Dr. WINDLE had been very much surprised to hear that the fifth year was added for the purpose of introducing the preliminary subjects. He had always understood that it was added with the object of obtaining more clinical instruction, and in his university—Birmingham—they had as much as three years of the instruction. Birmingham was not prepared to alter its arrangements in the direction suggested by the motion, which, if not unanimously agreed to, would be mere waste paper.

Dr. McVAIL said that there had been no formal consideration of this matter by the Scotch Universities, but he was perfectly satisfied that not one of these universities would fall in with the proposal now made. Nothing had occurred to condemn the five years' system, or to lessen the importance of the three preliminary subjects as part of the regular medical course, and surely the Irish and Scotch bodies were not to tumble down the system that had been carefully built up in order to get this little system of preliminary scientific education, and all, too, for the sake of the two Royal Colleges.

Mr. HORSLEY assured the Council that the profession throughout the country was watching this matter very closely and was fully aware that the discussion of it was no academic one. They understood that it was the revolt of two licensing bodies against the Council, and the general practitioners throughout the country were of one mind and that was that the authority of the Council should be maintained. The resolution now before them would have no effect unless the second recommendation was passed, and if they read the second into the first they would find that they formed a proposal by which the authority of the General Medical Council was destroyed. He could not read it in any other way and he told the Council that that would be appreciated throughout the country by the profession at large as a very serious blow at education.

Mr. YOUNG said that his university (the Victoria) was waiting for the action of the Council. Their position, however, was almost expressed in the words of the Dublin resolution, and, like Dublin, they should hold themselves free to deal with the five years' course in the interests of the students.

Dr. GLOVER thought it must be the desire of every member of the Council to see this question disposed of. Mr. Horsley seemed to think that if the London University could only do this preliminary scientific work it would be all right.

Mr. HORSLEY: That is not my suggestion, but I agree with it.

Dr. GLOVER: If the London University took the Royal Colleges into its care all would be right. Does Mr. Horsley think that no good education is given out of the London University?

Mr. HORSLEY: That is a misrepresentation.

Dr. GLOVER: You will excuse me just putting it in my own

form. I am not an authority, but does not Mr. Horsley think that scientific instruction should be conducted by a university? He (Dr. Glover) went on to say that the time was come for them to recognise that that was not the trend of public opinion nor was it the opinion of public persons. There was a disposition to get science introduced into the schools and to make it an essential part of secondary education, and if they went against that they went against the best opinion of the Council. For instance, Sir William Gairdner thought the Colleges were right in throwing back scientific education on the schools and believed that boys would get more chemistry, and more chemistry of the right sort, in their school life than in some of the classes of the medical schools.

Mr. TICHBORNE agreed that if they adopted the motion they would be taking a retrograde step.

Dr. LITTLE felt that he must vote against the motion. One member had spoken of the proposal as one to take the Royal Colleges off the rails. To his mind it was one to take the Medical Council off the rails. Dr. Norman Moore had satisfied him last session that the Royal Colleges had done much to make their plan work well, but he (Dr. Little) must vote against the motion because he thought that the Royal Colleges should have thought of this before they gave their acquiescence to the five years' scheme. It was hardly becoming to them and greatly disturbing to the work of this Council that the matter was introduced now. His great reason for voting against the motion was that the system it would set up would substitute examinations for education.

The PRESIDENT asked Sir Christopher Nixon if in the event of his motion being carried he proposed to move the second recommendation.

Sir CHRISTOPHER NIXON: I do not. I disapprove of it.

Dr. MACALISTER said that a memorial on the subject had been received from professors and teachers in Scotland and perhaps it should be read before the vote was taken.

The document, which was then read, is printed in another column. It was signed by 17 names of professors and teachers in the University of Glasgow, St. Mungo's College, Glasgow, Extra-Mural Medical Colleges in Glasgow and Edinburgh, and Dundee University College.

Mr. BROWN wished as a member of the Royal College of Surgeons of England to state that the Members of the College were not at all in sympathy with the position taken up by the representative of the College (Mr. Bryant) in this Council. At their last meeting a resolution proposed by him was carried by a large majority to the effect that the Members regretted the policy of the Council of their College, that they were acting disloyally to the General Medical Council, and that their action must encourage other bodies to follow in the same direction and must result in materially lowering the standard of education.

Sir JOHN WILLIAMS remarked that before voting the Council should be in possession of a knowledge of the way in which science was taught in these schools which were so much tabooed and treated with contempt by this Council. In recent years modern science had been established in all the good schools throughout the country. There were many schools which were not public schools but higher grade schools where science was taught very liberally. It would be a good thing, an important thing, if this Council were to recognise them as institutions where the training of young boys might go on, as it was the case that when young men went to the universities they had done a great part of the work which entered into their final examination. If the motion was carried he should move that the registration should be after the arts examination and before the preliminary scientific education.

Dr. BRUCE hoped that the Council would pass the motion, but he was one of those who believed that the course which the Royal College of Surgeons of England had taken in this matter was not proper for any body connected with the General Medical Council. Their action had been such as would end in only one way—the introduction of the one-portal system.

After a short reply from Sir CHRISTOPHER NIXON, the Council divided, when 10 voted for the motion, 17 against it, 2 declined to vote, while 2 were absent.

Sir Christopher Nixon's motion was accordingly rejected, and the PRESIDENT intimated that that disposed of the Education Committee's report.

The Council adjourned.

TUESDAY, DEC. 3RD.

The Council met again to-day, Sir WILLIAM TURNER being in the chair, and by sitting later than usual succeeded in getting to the end of its session.

*Mr. George Brown and the Chair.*

When the minutes of the proceedings yesterday on this subject were under consideration it was arranged to insert words to the effect that Mr. Horsley entered a protest against questions of privilege being raised upon irresponsible reports of members' speeches.

*Re-election of Sir William Turner as President.*

The next business was to receive the following letter from the President, viz. :—

General Medical Council Office, 229, Oxford-street,  
London, W., Dec. 2nd, 1901.

DEAR CHAIRMAN OF THE BUSINESS COMMITTEE.—Acting on the undertaking given in my address on Nov. 26th, I now place my resignation of the office of President in the hands of the Council as from Tuesday, Dec. 3rd.

I take this opportunity of expressing to the Council my sense of the honour of the position to which I was elected three years and a half ago and my acknowledgment of the continuous support which the Council has accorded me in the discharge of the highly responsible and onerous duties attached to the office of President.

Believe me, very faithfully yours,

WM. TURNER.

Sir William Turner withdrew from the chamber and his place in the chair was taken by Mr. Bryant, the senior treasurer of the Council.

Dr. PYE-SMITH moved :—

That Sir William Turner be re-elected President of the Council for a further period of five years, provided that he remains so long a member of the Council.

No elaborate eulogy upon the qualities of Sir William Turner were, he said, required from him. All the members knew his scientific eminence and his great experience in university matters and they had all experienced his constant courtesy, punctuality, and good temper. They had all observed the benignant solemnity with which he addressed delinquents in carrying out perhaps the most important and certainly the most painful of the duties imposed upon this Council, but of all his qualities that which appeared to him the most admirable was his patience. The Council were glad to learn that the ancient and learned University which he represented had wisely re-appointed him her representative for another period of five years.

Dr. ATTHILL, in seconding the motion, said that it would be a serious thing to the Council if it were to lose the services of Sir William Turner.

The ACTING PRESIDENT said he would now put the motion.

Mr. BROWN asked to be allowed to say a word in support of it.

Dr. PETTIGREW said that they should all wish to speak in support of the motion, but he hoped the reappointment would be quite unanimous without any speech from Mr. Brown.

Mr. BROWN said that all he desired to say was that throughout the time he had had a seat at this board he had met with uniform, he might say sympathetic, courtesy from the President and he felt it his duty to state this and he hoped it would be publicly recorded. He would further state that if any member had met with anything to the contrary it was his duty to say so here and not about the country.

The ACTING PRESIDENT put the motion and declared it carried by acclamation.

Introduced by the mover and seconder, Sir WILLIAM TURNER returned to the chamber, and after the decision of the Council had been announced to him by Mr. BRYANT he resumed his place in the chair.

The PRESIDENT said that he would like to say a few words on this occasion. When the Council did him the honour three and a half years ago to ask him to take the chair he deeply felt the responsibility of the situation. He felt it the more on account of his place of residence and the fact that so much of the business of the Council was to be transacted when he was living 400 miles away. He had great doubts in his own mind at the time whether it would be possible with his living at that distance for the work to be performed in a way that would satisfy himself because he thought perhaps in this matter he was as keen a critic as any member of the Council, and he wished to put on record that if it had not been for the invaluable assistance which he had received

from the Registrar (Mr. Allen) it would not have been possible for him to do the work in a satisfactory manner. Mr. Allen had acted throughout his tenure of office with the greatest consideration towards him because they must keep this in mind, that though the part of the business of the President which came most prominently before the public was that which took place in this Chamber and was duly reported upon, yet during the intervals between the meetings of the Council a large amount of business, in fact, almost daily business of some kind, had to be brought before the notice of the President and considered by him. Mr. Allen had always sent him every item of business which he had to consider arranged and prepared in a way which enabled him at once to grasp the chief point that he had to take into consideration, and so Mr. Allen had greatly lightened his labours. Now he was satisfied that he would receive from Mr. Allen in the future as in the past the same loyal coöperation, and he thought that he might say on behalf both of Mr. Allen and himself that whoever followed him in the chair would find that the business of the office during his tenure of the presidency had been so methodised and arranged that no item of business that had ever had to come before him but they would find in its proper place duly minuted, so that his successors could at once if they required lay their hands upon it. He hoped that health and strength might be given to him, for a period at any rate, to continue in this work. He could not in the natural course of things look for the full period of five years for which he understood they had chosen him, but he hoped that he might be able to do his duty towards them and towards their common profession, because that was how they had to look on this question. They were the great administrative body of their profession and they had to strive, all of them individually, to do their duty to that great profession so that it might continue to advance and that in no matters might they ever lag behind. He thanked members heartily for again reposing their confidence in him.

*The Council and the English Royal Colleges: Special Committee Appointed.*

Dr. MCVAIL moved :

That a committee be appointed to prepare a report on the differences that exist between certain licensing bodies on the one hand, and the General Medical Council on the other, regarding the courses and conditions of study, and the recognition of the institutions and schools in which the required courses may be taken; and that the report be considered by the Medical Council at a special meeting, when the Council will decide what action, if any, shall be taken, and in particular whether the circumstances are such as to require action to be taken under Section 20 of the Act of 1858.

The differences between the Council and the English Royal Colleges, Dr. McVail said, had never been more apparent than during this session of the Council. They arose upon the interpretation of Sections 18 and 20 of the Medical Act of 1858. Section 18 said that the several colleges and bodies in the United Kingdom mentioned in Schedule A shall from time to time when required by the Council furnish them with such information as they might require as to the courses of study and examinations to be gone through in order to obtain the respective qualifications mentioned in the schedule and the ages at which such courses of study and examination were required to be gone through and such qualifications were conferred, and generally as to the requisites for obtaining such qualifications; while Section 20 said that in case it appeared to the Council that the course of study and examinations were not such as to secure the possession by persons obtaining the qualification of the requisite knowledge and skill for the efficient practice of their profession it shall be lawful for the Council to represent the same to the Privy Council. The Council had regarded their position under the Act as that of laying down the minimum standard of study to be required by the various universities and licensing boards. These universities and boards undoubtedly could add to the course of study, but under the Act; the Council had proceeded as if they could not subtract from the course of study. Obviously if the medical profession were to be governed in such a way that every name appearing on the Register under the keeping of this Council was that of a person who was adequately taught, only that body could decide what the adequate study should be, otherwise there could be no harmony and no minimum. All the universities and bodies in existence prior to this Council had charters, and in these charters they had rights

quite clearly stated and defined, but all these rights were modified by the Act bringing the Council into existence. Whatever these rights might be they must be carried out as regards study subject to the approval of this Council, and if this Council did not approve of the study then it was not the privilege but the duty of the Council to report the matter to the Privy Council. The Council had laid down certain regulations as to the study of particular subjects and the English Royal Colleges had not conformed to these as regards the conditions under which they might be taken. This action of the English Royal Colleges came to the notice of the Council three years ago, so that there was no question of want of patience on the part of the Council. The Education Committee had made reports upon it and the Council had decided that its recommendations and its policy must be upheld. The Colleges, on the other hand, had shown no disposition to meet the views of the Council. On the contrary, the departure from the Council's recommendations with regard to the first year of preliminary scientific study had led them to question the right of this Council to inspect any examinations except the final examinations in medicine, surgery, and midwifery. It had led them practically to take their students out of the Students' Register and to consider themselves free to deal with the preliminary examination as they thought fit. It was clear that what the English Colleges had done other bodies would regard themselves as at liberty to do, and the whole work of this Council in building up a system of education would crumble away. In his opinion it was of the utmost importance that the Council should determine whether or not in these grave circumstances they should take action. What he proposed was that there should be a special committee who would prepare a statement of the case and present it to an independent counsel and submit their report to a special session of the Council.

Mr. YOUNG, seconding the motion, said that he considered that it was essential in the interests of medical education and for the guidance of the licensing bodies as a whole that this Council should with as little delay as possible declare their policy and make a clear, explicit, and emphatic statement as to the course which they intended to pursue with regard to the conditions of registration of medical students and the conditions of study subsequent to registration. It was, of course, notorious that there were other bodies besides the English Colleges which deviated from the recommendations of the Council.

Dr. GLOVER said that he had never heard a more grave motion proposed upon a flimsy basis. His first objection was that it involved a certain amount of disrespect to the Education Committee.

Sir JOHN BATTY TUKE: There is no feeling of that sort.

Dr. GLOVER said that he had been a member of the committee for nearly 15 years and he knew that what he had said must be the innate feeling of most of his colleagues. Then he objected to the multiplication of special sessions and to the expense involved. He held that this subject would not be settled by meetings as much as by the reflection of members in the intervals between meetings. It was absurd to talk about putting the matter before an independent counsel. Mr. Muir Mackenzie, if he had any prejudice, must be in favour of the Council and he told them plainly that the Council had no power. What he (Dr. Glover) proposed was that they should leave the matter alone, at any rate for another six months.

Dr. ATTHILL said that while he regretted the action of the English Colleges he did not think that Dr. McVail's proposal would contribute to the settlement of this question. The facts were perfectly well known to every member of the Council and the only action which he could understand was that they should report them to the Privy Council.

Mr. HORSLEY said that he regarded this motion as the first attempt to get the Council to look at the question at issue properly. He believed that Parliament and the central Government considered that they had handed over the question of medical education to this Council and that they were not aware of what had been going on recently. In these circumstances he believed that it would be a good procedure if their legal adviser supported the idea of going to the Privy Council and asking the opinion of that body as to who was the highest authority on medical education, this Council or no.

Dr. LITTLE, while objecting to a special session, said it was most important to have this matter settled.

Sir WILLIAM THOMSON insisted that the motion of Dr.

McVail was the legitimate outcome of the discussions that had taken place and said that if the proposal had been to report to the Privy Council he should have supported it.

Dr. PYE-SMITH said that surely the object of the appeal to the Privy Council was to prevent the scandalous lowering of the standard in any case, and he asked whether anything of the kind could be suggested in the case of the English Royal Colleges. No one would suggest that the men admitted to this diploma would be less well-educated than the diplomates of other bodies. It was impossible to bring all bodies to exactly the same point, and they ought to remember that there were defects elsewhere if there were defects in the case of the English Royal Colleges. He confessed that he had noticed upon these occasions that some of the noisiest showmen of pebbles had come from what he might almost describe as crystal palaces. This Council derived their position not so much from their authority as from their influence. They had limited legal powers, and they had, on the whole, exercised them with judgment and moderation, and as they continued to do so their influence would gradually extend. In this particular case he thought that they might trust to peace and the progress of reason to make the right side triumph.

Sir CHRISTOPHER NIXON said the difficulty which he had was that he could not follow his friend who had just spoken in asking that the Council should adopt entirely a policy of peace, that they should endeavour to get a *via media*. It was a matter of regret to him that there should be a difference between the General Medical Council and two great incorporations like the Royal College of Physicians of London and the Royal College of Surgeons of England. But they could not shut their eyes to what would be the result of these Colleges insisting upon taking a particular action, on the one hand, which was in direct controversion to what was laid down by the General Medical Council on the other. And what they forgot was the danger that would arise from not being able to find a *modus vivendi* as between the parties, for at the end of three years' contention they were just as far from reconciliation as ever. The action taken by the Colleges in question reduced the powers of this Council to a nullity. It brought things to this—that the General Medical Council had practically no powers. The danger in not having it shown that the Council had powers was that they afforded an opportunity for the operation of a process of disintegration—that was, they would have each individual incorporation—some from not very particularly worthy motives—instituting a set of regulations which they would say they, equally with the English Royal Colleges, had the right to adopt. That was the danger, and it was threatened from various quarters. How was it to be got rid of? Dr. Glover was continually preaching peace, and to-day accused members of wasting the Council's time and money because it had not put upon its minutes a series of resolutions on this matter and that. The Council, he thought, should be the judge of their own actions. He was not quite sure that there was any occasion for postponing action by the Council or postponing to ask the Privy Council to say whether the General Medical Council had the power to direct medical education throughout the three kingdoms. Let the Privy Council say in reply that the General Medical Council had gone beyond their rights and had no power to direct the licensing corporations, or, on the other hand—and according to the provisions of the Medical Act—that the Council had acted within their rights in determining the medical curriculum and the subjects of medical study and how they should be taken. If the Privy Council gave decision to the latter effect he presumed that the licensing bodies in England would bow the head. If, on the contrary, the Privy Council said that the General Medical Council had not the power, they ought to try in every way possible to get the power, because it would be of advantage not only to the profession but to the public at large. It was of the greatest importance, in his opinion, that some definite action should be taken by the Council, and at once.

In answer to the PRESIDENT Mr. BRYANT said: I have nothing to add to what I said the other day on this subject, and I do not wish to take part in this debate.

The PRESIDENT: Dr. Moore, have you anything to say?

Dr. NORMAN MOORE: Not I, sir.

Dr. MACALISTER said that no one could say that he was not prepared to fight for the Council's position, but he also looked at the possibilities of the result of a fight. If the

Council examined the clause under which it was proposed to take action, he thought they would see that the only thing they could ask the Privy Council to do would be to deprive the English Royal Colleges of their diplomas. Could they imagine themselves going before the Privy Council with the demand that the Licences of these English Royal Colleges should cease to be registrable qualifications? The Privy Council, sitting as a judicial body, would not oblige the General Medical Council by giving a legal opinion as to whose power was paramount. This Council could not bring a case before the Privy Council unless they absolutely demanded, on the result of their investigations, that these diplomas were unworthy of being registered. They should not have any *locus standi* unless they were prepared to state that. He for one was not prepared to do that, and he thought that most of those around the table were not prepared to state that. There was no question that the English Royal Colleges by their independent action had dealt a blow at the importance of the three first year's subjects that would be felt for some time, but, notwithstanding, he did not feel that the Council had lost all influence. So long as they kept their hands on the medical students and kept their hands on the conditions of admission to the students' registration they should have a powerful lever with which to act on the teaching bodies and on the parents and guardians of possible medical students.

Dr. McVAIL could only express his great surprise at the speech which had just been made by Dr. MacAlister. Dr. MacAlister thought that the Council should sit and wait and hope that grace might enter into the English Royal Colleges. But what was to happen in the meantime? The University of Dublin had shown. Dr. MacAlister also seemed to suppose that the Privy Council would not refuse recognition to the Licences of two such great bodies as the English Royal Colleges. But he for one presumed that the Privy Council would deal with these two great bodies as they would deal with the smallest bodies in the country, and that would be justly and rigidly. The point was, that these two bodies were accepting a first year's course of study which in the opinion of the General Medical Council was "insufficient"; but as the whole matter was involved they must get up a clear statement of the facts, and that was the reason why he proposed his motion.

On a division 16 voted for the motion and 10 against it. Three members did not vote, while two were absent.

The motion accordingly was carried.

Dr. McVAIL moved, as a consequence, that the committee should consist of three members representing England—Mr. Bryant, Dr. Norman Moore, and Mr. Young; two representing Ireland—Sir William Thomson and Mr. Ball; and two representing Scotland—Dr. McVail and Sir Hector Cameron; and that the President should be *ex-officio* a member of the committee. He also proposed that the special meeting of the Council to consider the committee's report should begin on the fourth Tuesday of February next.

These proposals were unanimously consented to, and it was further agreed that Dr. McVail should be chairman of the committee, and that the committee should have power to ask counsel's opinion—that of Mr. Muir Mackenzie, their legal adviser, and that of any other counsel, if thought necessary.

#### *The Midwives Question.*

Mr. BROWN wished to know if the Council at the special meeting just decided upon would be able to consider any Midwives Bill that was introduced into Parliament early next session and sent in draft from the Privy Council asking the Medical Council's opinion on it.

The PRESIDENT: The first thing the Council will have to consider at the special meeting will be the report of the committee we have just formed, but if a Midwives Bill is sent to us in time I think the Council would consider it before separating.

#### *Recognised Scientific Institutions.*

The Council resumed consideration, adjourned from Wednesday, Nov. 27th, of a list of scientific institutions, other than universities or schools of medicine, recognised by the licensing bodies, presented by the Executive Committee in accordance with the desire of the General Medical Council that the list of institutions should be re-arranged by the committee.

Dr. MACALISTER moved the approval of the following list of scientific institutions, other than universities or

schools of medicine, at which the course of medical study might be commenced by applicants for registration in the Medical Students' Register:—

BRADFORD: Technical College.  
BRIGHTON: Technical Day College.  
BRISTOL: Merchant Venturers' Technical College.  
CAMBRIDGE: Girton College, Newnham College.  
CHELTENHAM: Ladies' University College.  
DERBY: Technical College.  
DUBLIN: Royal College of Science for Ireland, University College.  
EGHAM: Royal Holloway College.  
EXETER: Royal Albert Memorial College.  
LONDON: Royal College of Science, Bedford College, Birkbeck Institute, East London Technical College, Central Technical College, Westfield College.  
NEWCASTLE: Durham College of Science.  
NOTTINGHAM: University College.  
PRESTON: Harris Institute.  
READING: Reading College.  
SOUTHAMPTON: Hartley College.

Sir CHRISTOPHER NIXON seconded the motion.

Dr. NORMAN MOORE said that this list of scientific institutions was not thoroughly satisfactory to him as a member of the Council, seeing that the Council had not satisfied itself in respect to the efficiency of any one of the institutions. He moved as an amendment:—

That the list of scientific institutions, other than universities or schools of medicine, do consist of the teaching institutions where physics, chemistry, and elementary biology are taught, recognised by each licensing body, as stated in the list forwarded each year, provided that the list in each case be accompanied by the statement that after due inspection the licensing body is satisfied that each institution so recognised possesses sufficient laboratory accommodation and appliances for the efficient teaching of the required subjects.

Mr. BRYANT seconded the amendment.

Dr. MACALISTER said that the amendment would knock the bottom out of everything already done because it included every secondary or higher grade school on the list.

After some conversation,

Dr. NORMAN MOORE said that he was only anxious to show that the English Royal Colleges were anxious to take every possible way to meet the Council. Instead of fighting it they had profound respect for it. It would be far wiser to accept his proposal, because it carried out all that the Council originally recommended.

On a division, the amendment was rejected by 16 votes to seven, and the motion of Dr. MacAlister became the finding of the Council.

On the motion of Dr. MACALISTER, seconded by Dr. WINDLE, the Students' Registration Committee were empowered to give provisional approval on behalf of the Council to other scientific institutions of the same status as those now passed which might hereafter be recognised by licensing bodies, the names of such to be reported half-yearly to the Council.

#### *Instruction in Anæsthetics.*

The Council then considered a report by their Education Committee on a communication from the Council of the Society of Anæsthetists. The communication was as follows:—

At a meeting of the Society of Anæsthetists held April 19th a resolution was carried empowering the council to direct the attention of the General Medical Council to the desirability of including in the curriculum of medical education the subject of anæsthetics. The council of the Society of Anæsthetists ventures, therefore, to place before the General Medical Council the following facts:—(1) There is at present no compulsory training in anæsthetics in any hospital or teaching centre in Great Britain and Ireland. (2) There is no examination in this subject testing the knowledge or experience of students before admission to practice. (3) The responsibility of giving anæsthetics involves risks to life. (4) Every member of the medical profession is liable to be called upon to give anæsthetics, and very many are compelled to undertake that duty without help, advice, or guidance. (5) It is therefore submitted that the importance of the subject, touching as it does the actual risks to life, renders it essential that the teaching of the administration of anæsthetics should be included in the schedule of compulsory subjects. (6) While not venturing to suggest how such teaching and examination should be conducted, the council of the society is prepared to furnish details, founded on their experience, should the General Medical Council consider their doing so desirable and useful.

Sir JOHN BATTY TUKE said that the committee's report on this communication was as follows:—

The committee fully appreciate the importance of proper teaching in the subject of anæsthetics, but they are of opinion that it is not expedient that it should be compulsorily included as a separate subject of the medical curriculum.

He moved that the report be received, entered on the minutes, and approved of.

Dr. NORMAN MOORE seconded the motion.

Mr. HORSLEY hoped that the committee would somewhat

re-arrange the wording of their report. The teaching of anæsthetics as a separate subject sounded very formidable, but if the Council included the subject in the final examination he thought that the Council would be taking their proper position as regards it, for the schools were teaching it, they were far in advance of the Council in regard to it, and they ought not to be behind the schools on a question of medical education. Although he quite sympathised with the report and the idea that they should not magnify the subject, he still thought that it ought to be specifically mentioned in the Council's recommendations as being included in the final examination.

Mr. BROWN suggested whether it might not meet the case if a candidate on going up for the final examination showed a certificate that he had given attendance in a certain number of cases.

Dr. PYE-SMITH had no doubt that the subject was taught in every hospital. It was one that students were willing to learn. Surely they ought to be satisfied, therefore, that the thing was done well, and there was no occasion to magnify its importance.

The PRESIDENT remarked that the subject was taught in all the Scotch universities.

Dr. HERON WATSON said that not only was that so, but nurses and dressers were taught it in the Scotch hospitals and infirmaries and there were no accidents with anæsthetics there.

Sir John Battý Tuke's motion was carried.

#### *Financial Relations Committee.*

On the motion of Dr. MACALISTER, seconded by Mr. BRYANT, the Council received from the President, as Chairman of the Financial Relations Committee, and entered on their minutes, the following interim report:—

The committee report that the present relations between the General and Branch Councils are determined by the Medical Act, 1858. To modify these relations and secure a satisfactory financial basis an Amending Act will be required. The committee are not prepared at this meeting to recommend the lines on which the amendments should be framed, and ask the Council to continue the committee to the next session.

#### *The Sinking Fund.*

Mr. TOMES asked the Council to pass this motion:—

That the annual payments of £215 12s. 6d. to the Alliance Insurance Company, which form a sinking fund, be discontinued, under the terms of the agreement with the insurance company.

This fund, he explained, had been in existence for three years. But as it was one for an accumulation that would be enjoyed only 50 years hence at the expense of money which the Council required now he thought that it would be well if the annual payments were discontinued. If stopped now the Council would be able to recover the first year's payment and 10 per cent. on the "rest."

Dr. ATTHILL seconded the proposal. He said that he had opposed the origination of the sinking fund, and he believed the Council would be better without it. It was inaugurated to cover the expenditure on their premises in Oxford-street, but he was informed that so much had property in the vicinity risen in value since they acquired the premises that if they were selling to-morrow they would secure a profit of £20,000 on the cost. It would be very well to pay if they had an excess of income, but they had no excess, and, moreover, were every year selling out Consols in a falling market. He hoped the Council would pass the motion.

Mr. BRYANT, as senior treasurer, opposed the motion. He considered the sinking fund principle a sound one and that the continuance of the payments in respect of it would be most profitable to them in the future.

After further discussion it was resolved to refer the motion to the Finance Committee to report upon it next May, Mr. Tomes being added to the committee for this particular subject alone.

#### *Borrowing from the Dental Fund.*

On the motion of Mr. BRYANT, seconded by Mr. TOMES, it was agreed:—

That in order to obviate the necessity for the English Branch Council to sell out Consols at their present depreciated value the General Council sanction the temporary advance of £600 at 3 per cent. by the Dental Fund to the English Branch Council.

It was stated that this was only the return of a good turn, for at the inception of the Dental Fund the English branch had lent to it somewhere about £1100.

*The Pharmacopœia.*

Dr. MACALISTER presented the report of the Pharmacopœia Committee :—

The Pharmacopœia Committee have to report that up to the present date 31,268 copies of the British Pharmacopœia, 1898, and 320 copies of the Indian and Colonial Addendum, 1900, have been disposed of. In accordance with the Council's decision of June 7th the President in July authorised a fresh issue of 1500 copies of the Pharmacopœia. The opportunity was taken to insert a slip correcting a few minor errors in the text.

At the request of the Executive Committee the Secretary of State for the Colonies addressed a circular despatch, dated July 13th, 1901, to the officers administering the governments of the various colonies. The despatch sets forth the rights and duties in relation to the publication of the Pharmacopœia assigned to the Medical Council by the Medical Acts, 1858 and 1862, and communicates the desire of the Council that any colonial legislation for the adoption of the Pharmacopœia in the colonies should contain provisions for the safeguarding of the Council's rights.

Replies to the despatch received from a considerable number of Colonial Governments have been forwarded to the President by direction of Mr. Chamberlain, and from these it appears that the statutory claims of the Council will receive due attention from the Governments in question, should occasion arise for local legislation in reference to pharmacy.

The President has referred to the committee a communication from the Secretary of State for India asking that 3500 copies of the Indian and Colonial Addendum may be furnished for the use of the Government of India. In view, however, of the conditions obtaining in that country the Secretary of State requests that certain alterations affecting three of the formulæ in the Addendum should be made in the copies despatched to India.

The committee have considered in what manner this request of the Indian Government may best be met, and they are of opinion that by sanctioning the insertion of two short paragraphs in the appendix, with consequential alterations in a few lines of the text, the Council can do what is necessary to adapt the Addendum for official use in India.

He explained that the publishers of the book had informed the Council that they were £1500 to the good in respect to the British edition. The sale of the Indian Addendum had been rather disappointing, as only 320 copies had been asked for outside the Government order. For that order alterations required to be made in formulæ, but what these were he could explain only *in camera*.

For a while the Council sat in private. On the readmission of the public,

The PRESIDENT intimated that the Council had passed two resolutions as follows :—

1. That the issue of a "Government of India edition" of the Addendum, including the modifications communicated to the Council *in camera*, be sanctioned by the Council for use in India. 2. That the Executive Committee be empowered to take on behalf of the Council the necessary steps for the publication of the "Government of India edition" of the Addendum.

*The Apothecaries' Hall, Dublin.*

Mr. BRYANT submitted a report by the Examination Committee on the inspection in July last of the examinations of the Apothecaries' Hall, Dublin, by the Inspector, Dr. W. P. Herringham, and the Assistant Examiners in Surgery, Mr. Alexis Thomson and Mr. H. G. Howse, appointed by the General Medical Council, together with remarks by the body inspected. He also submitted a report on the inspection in October last of the examinations of the same licensing body. In the first of these two reports the committee stated :—

It is satisfactory to read that the "Inspector" and the surgical examiners of the Apothecaries' Hall, Dublin, report of the July examination that it was "thoroughly and satisfactorily conducted"; and the standard of knowledge required was satisfactory; also that the governor and court of the body inspected "were pleased to observe that these reports continue to be so favourable." Your committee note that there were but two candidates for the first examination, one for the second, none for the third, and four for the fourth or final. One of the two candidates for the first examination was passed in anatomy and rejected in pharmacy. The second candidate passed in all the subjects of the examination. The single candidate for the second examination passed in anatomy and materia medica. Of the four candidates for the final examination one passed in medicine and ophthalmology and was rejected in surgery and obstetrics, whilst the two other candidates were rejected in all subjects. The above record does not seem satisfactory to this committee, as it clearly indicates that candidates for this examination are of an inferior class of men, who seem to be incapable of passing a good examination in any important group of subjects, and can only obtain their licence to practise by what this Council condemns—the piece-meal method of passing examinations long spun out. The introduction of such men into the profession is not, from your committee's point of view, to the advantage of the public.

The October report stated that there were no candidates for the first, second, or fourth examinations, but there were two for the third, both of whom were candidates in April. One of these passed in hygiene but was rejected in pharmacy. The other passed in all subjects.

These reports, on Mr. BRYANT's motion, seconded by Dr. PETTIGREW, were received and entered on the minutes.

On the motion of Dr. MACALISTER, seconded by Mr. BRYANT, it was agreed :—

That the attendance of Dr. Herringham be not required at the final examination of the Apothecaries' Hall, Dublin, on the occasion in 1902 when the Council's Inspector of final examinations is present.

*Public Health.*

Dr. BRUCE presented the following report :—

The Public Health Committee beg to submit the following Report :  
1. Correspondence with the India Office with regard to recognition of Major Weir and others as qualified to give certificates in laboratory and outdoor work. 2. Communication from the Conjoint Board of Physicians and Surgeons in Ireland as to the sufficiency of instruction and training in public health in the cases of two candidates admitted for examination. 3. Report of a meeting with a deputation of London teachers of public health.

With regard to 1 the committee have to explain that the request of the Government of India came to the Council office in July. The President was of opinion that an early answer should be sent and that the matter could not be delayed until the November meeting. No other answer than that which was given seemed possible in view of the repeated declarations of the Council that the public health diploma is one implying a specially high standard both of study and examination.

With regard to 2 the committee recommend the Council to direct the Irish Branch Registrar not to register any diploma in public health which may have been obtained by Dr. Alfred Moore and Mr. M. B. Costello, inasmuch as they have not complied with the requirements of the curriculum, and recommend the Council to send an answer to the Conjoint Board to that effect.

With regard to 3, the committee are of opinion that the resolutions and rules adopted by the General Council on December 5th, 1900, for the diploma in public health should be amended by the substitution of three months for six months' outdoor sanitary work now required, the committee being, however, still of opinion that a total period of not less than nine months should be devoted to public health study.

The first and second recommendations having been adopted,

Dr. BRUCE moved the adoption of the third. He explained that it was thought desirable to make the change thus proposed because of the difficulty that had been experienced, in London particularly, in securing six months' "day-by-day" association "in the duty, routine and special, of public health administration under the supervision of the medical officer of health of a county or of a single sanitary district." So difficult had it been in the metropolis to get teachers that the whole country had been thrown open as a training-ground for candidates for diplomas.

Dr. NORMAN MOORE seconded the motion.

Dr. MACALISTER objected. The existing rules and regulations, he said, had hardly yet come into operation. He thought that only one examination had been held under them. They had been already more than once changed in the past three or four years, and it was very inconvenient generally that the Council should not know their own mind on the matter. With regard to the change proposed, he believed that the same difficulties experienced in respect to the six months would be found operating if three were substituted. The six months, moreover, had been in force for years, so the question of difficulty which was now raised was not new.

It was resolved to refer the recommendation back to the committee for a report upon it next session.

*Registration of Students.*

Sir HUGH BEEVOR submitted a report by the Students' Registration Committee on exceptional cases dealt with by them.

The report was approved and entered on the minutes.

*Final Examinations.*

On the motion of Dr. MACALISTER, seconded by Mr. BRYANT, it was resolved to appoint Sir George Duffey as inspector of the final examinations for the year 1902.

*The Recognition of Italian Medical Degrees.*

The following "notice of motion" by Mr. HORSLEY stood on the programme :—

That it be represented to His Majesty's Privy Council that in reference to the Order in Council imposing on the General Medical Council the duty under Part II. of the Medical Act, 1886, of the official recognition of Italian medical degrees, the funds at the disposal of the General Council do not allow of any inspection of the examinations of the Italian universities being made, as is applied to the examinations of the universities in the United Kingdom, and that application should be made to the Privy Council to obtain a grant in aid for this purpose.

On this Order being reached Mr. HORSLEY intimated that he withdrew it.

*Inspection of Preliminary Examinations.*

The following motion, moved by Sir JOHN BATTY TUKE and seconded by Dr. NORMAN MOORE, was passed :—

That the sum of £50 be placed at the disposal of the Education Committee for the purpose of providing for the inspection of certain of the

recognised Preliminary Examinations in general education during the year 1902.

#### *Multiplicity of Examinations.*

Dr. MACALISTER, on behalf of the Business Committee, asked the Council to place on their minutes a memorial addressed to them and to the councils of the Pharmaceutical Society, the Incorporated Law Society, the Royal Institute of British Architects, the Institute of Civil Engineers, the Institute of Actuaries, the Institute of Chartered Accountants, and the Society of Accountants, by the committee of the Headmasters' Conference. This document called attention to the

grave inconvenience and waste which arise from the multiplicity of examinations for entrance to professions. The Law Society, Actuaries, Architects, Chartered Accountants, and Society of Accountants had entrance examinations of practically the same standard, but as each included one or more special books the effect of the diversity upon schools was very serious, while there was the expense of five separate examinations whereas one would serve. The councils of the five societies enumerated, "as well as two others (the General Medical and the Pharmaceutical), which hold no examinations of their own, publish lists of public examining bodies whose certificates they accept in lieu of their own. This arrangement, which is intended to save candidates from trouble and expense, is only very partially successful. For no two of these lists coincide; and almost every one of the examining bodies in question sets its own special books and has its own separate definition of history, geography, and elementary mathematics. For the majority of candidates and of schools, therefore, this well-meant concession presents the same difficulties in another form. The syllabuses of the professional examinations make it clear that all the councils have the same object in view, to ascertain whether the candidates have been sufficiently well educated on the usual lines. While sympathising with this desire, the Head Masters' Committee think the object can be better attained by much simpler means. They venture to suggest to the seven professional councils that a conference should be held between representatives of the councils, the Headmasters' Conference, the Incorporated Association of Head Masters, the universities, and the Board of Education. Such a conference might devise a scheme for a combined examination, the results of which could be accepted by all the councils concerned."

This memorial was entered on the minutes.

Dr. WINDLE thereupon moved :—

That the Council recognises the disadvantages arising from the present multiplicity of examinations qualifying for entrance to the various professions, but that, being unable itself to take any active step in the matter, the Council do forward the memorial from the Committee of the Headmasters' Conference to the Lord President of the Council with a suggestion that this is a suitable question for the consideration of the Consultative Committee to the Board of Education.

In supporting this motion Dr. Windle said that the Board of Education was the only body in this country able to establish a single examination in preliminary subjects, or say who should do it. The one thing which apparently was needful was to follow the example embodied in the Scotch "leaving certificate."

Dr. MACALISTER seconded the motion, which was at once agreed to.

#### *Vote of Thanks to the President.*

Dr. GLOVER, noting that the programme of business was finished, asked permission to propose a final motion—one that at the end of their controversial subjects was without controversy. What he wished to do was to propose a vote of thanks to Sir William Turner, their President, for his conduct in the chair during the session—a session in which he had had harder work than he had had in any of the sessions of the past. He (Dr. Glover) had sat at that Council for many years and had seen what were their President's courtesy and consideration to the members, but in no previous session had these qualities of his been more in demand and more happily illustrated, and he now wished to propose a vote of thanks to Sir William Turner for his conduct in the chair.

The Council responded by clapping their hands.

The PRESIDENT, in acknowledgment, said that Dr. Glover had more than once proposed a vote of thanks to him at the conclusion of the Council's business. For this one he thanked those who had responded, but he was sorry that he was not likely again to receive on the same initiative a compliment such as that which had just been paid to him.

The Council then rose.

#### THE TEACHING OF MEDICAL PHYSICS.

The following memorial to the General Medical Council protesting against the relegation of chemistry, physics, and biology to the school period of the education of medical students has been signed, as will be seen, by a highly distinguished group of Scotch teachers :—

The position of the purely scientific subjects of chemistry, physics, and biology in the medical curriculum being one of

the questions at present before the General Medical Council we would beg to submit the following expression of our views.

The proposal to relegate the teaching of these subjects to the school period appears to us a retrograde step and one which is calculated to have a most prejudicial effect on medical education. The object of these sciences in a medical curriculum is to ensure a real scientific training for the student and to inculcate scientific method which he can apply to his purely professional studies. Were a parrot-like knowledge of the mere facts and formulæ of science all that is desired the committing of these to memory might be done at school, but knowledge thus obtained is of little practical and no educational value.

Medicine is becoming more and more scientific in its methods, and it is only by a sound training in the principles of science that the medical man of the future can hope to keep abreast of its developments and be properly equipped for his practice.

What should be aimed at therefore by those who care for the proper training of the student and the consequent status of the profession is a knowledge of scientific principles.

In view of this it would be greatly to the benefit of the medical profession were the standard of the first professional examination in science even raised and certain alterations made in the course of study, such as compulsory practical work.

To acquire a scientific training of real value it is necessary that the student devote his whole energy to the subjects in question. This is manifestly impossible when the preliminary examination in general knowledge is impending.

The methods of teaching best adapted to give the desired result—a true scientific training—are quite distinct from those suited to the school, and, further, the power of grasping scientific generalisations is seldom developed till a later stage than that at which the preliminary examination should be passed.

In our opinion, therefore, no graver mistake could be made than that the General Medical Council should agree to the relegation of those subjects to the school period.

MALCOLM LAURIE, Professor of Zoology.

JOHN YOUNG, Professor of Zoology, University of Glasgow.

FREDERICK BOWER, Professor of Botany, University of Glasgow.

A. GRAY, Professor of Physics, University of Glasgow.

D'ARCY W. THOMPSON, Professor of Zoology, University of Dundee.

JAMES WALKER, Professor of Chemistry, University of Dundee.

J. P. KUENEN, Professor of Physics, University of Dundee.

J. M. WATSON, Professor of Chemistry.

PETER BENNET, Professor of Physics.

J. BELL TODD, Professor of Zoology.

J. SWANSON, Professor of Botany.

J. BLYTH, Professor of Physics.

BEATH HENDERSON, Examiner in Biology.

ARTHUR T. MASTERMAN, Lecturer on Zoology.

DAWSON TURNER, Lecturer on Physics.

IVISON MACADAM, Lecturer on Chemistry.

J. FALCONER KING, Lecturer on Chemistry.

Glasgow, November, 1901.

## THE ELECTION OF DIRECT REPRESENTATIVES.

### SCOTLAND.

Dr. W. BRUCE has been returned by a majority of over 100 votes as Direct Representative for Scotland upon the General Medical Council.

**THE ORGANISATION OF NURSING.**—The Society of American Women in London entertained the nurse delegates to the recent International Congress of Nurses at Buffalo at a reception in the rooms of the society at Prince's Hall on Nov. 29th. The delegates gave the results of their observations on nursing in America. There was a large gathering.

## Medical News.

**UNIVERSITY OF CAMBRIDGE.**—At the congregation on Nov. 30th the following degree was conferred:—

*M.B.*: J. S. Clarke, Gonville and Caius College.

The Allen Scholarship, of the value of £250 for one year, will be vacant in the Lent term. Candidates must hold a degree in the University and be under 28 years of age. They must be prepared to undertake research in some branch of medicine, mathematics, natural science, or moral science. They are requested to send in their names to the Vice-Chancellor not later than Feb. 1st, 1902.

**FOREIGN UNIVERSITY INTELLIGENCE.**—*Cracow*: Dr. August Wróblewski has been recognised as *docent* of Biological Chemistry.—*Göttingen*: Dr. Bickel and Dr. Waldvogel have been recognised as *privat-docenten* of Internal Medicine.—*Kiel*: The newly-established asylum for the insane has been placed under the charge of Professor Simmerling who will give clinical instruction therein.—*Naples*: Dr. Camaggio and Dr. Ugo De Rinaldis have been recognised as *privat-docenten* of Surgical Anatomy and Operative Medicine and Dr. G. Sorge as *privat-docent* of Diseases of Traumatic Origin.—*Vienna*: Dr. Kraft-Ebing has resigned the chair of Psychiatry and the charge of the Psychiatric Clinic. The former post will be filled by Professor Gabriel Anton of Gratz and the latter by Professor von Wagner-Jauregg. Dr. Heinrich Lorenz, *privat-docent* of Internal Medicine, has been granted the rank of Extraordinary Professor. Dr. E. Schiff, *privat-docent* of Dermatology, and Dr. K. A. Herzfeld, *privat-docent* of Gynaecology, have also obtained the same distinction.

**MEDICAL MAGISTRATE.**—The Mayor of Saltash, Dr. Robert Thornton Meadows, was sworn in as a justice of the peace for the county of Cornwall on Nov. 27th.

**ENTERIC FEVER AND MILK.**—At the meeting of the Newton Abbot Rural District Council held on Nov. 27th, Dr. H. B. Mapleton, the medical officer of health, reported 12 cases of enteric fever at Kingskerswell which he had traced to an insanitary dairy.

**OFFENSIVE TRADES.**—At the Liskeard Town Hall on Nov. 29th, a firm was summoned for carrying on the business of fellmongers without the consent in writing of the urban sanitary authority and was ordered to pay a fine of £2 and costs.

**PRESENTATION TO A MEDICAL PRACTITIONER.**—A presentation has been made to Mr. Stenson Hooker, M.D. Durh., by his friends and patients, on the occasion of his leaving Hastings for London, of a silver tea and coffee service and cake-basket, together with an oak tea-tray upon which is engraved a suitable inscription.

**DRAINS INTIMATELY ASSOCIATED WITH RELIGION.**—The Rev. F. Lawrence, honorary secretary of the Church Sanitary Association, preaching last Sunday in the parish church of Westow, near York, upon the text taken from the Epistle for the day, "Put ye on the Lord Jesus Christ," said that the Founder of the Christian religion, Who cared "as well for the body as the soul," expects His followers to do their best to secure fulness in respect of bodily well-being for all persons, and hence that drains are intimately associated with true religion.

**OTOLOGICAL SOCIETY OF THE UNITED KINGDOM.**—At a meeting of this society held on Dec. 2nd, the following gentlemen were elected office bearers for the next session, 1901-1902:—President: Dr. Urban Pritchard. Vice-presidents: Dr. Peter McBride, Dr. Edward Law, and Dr. Arthur W. Sandford. Honorary Treasurer: Mr. Alphonso Elkin Cumberbatch. Honorary Librarian: Mr. E. Cresswell Baber. Editor of Transactions: Mr. Arthur H. Cheate. Honorary Secretaries: Dr. William Milligan and Dr. W. Jobson Horne. Council: Sir William Dalby, Dr. Adolph Bronner, Dr. Dundas Grant, Mr. Charles A. Ballance, Mr. Stephen Paget, and Professor John B. Story.

**ST. ANDREWS GRADUATES' ASSOCIATION.**—At the annual general meeting held at 11, Chandos-street,

Cavendish-square, W., on Nov. 29th, the following officers were elected for 1901-1902:—President: Sir Charles Gage Brown, K.C.M.G., M.D. Vice-presidents: Surgeon-General W. B. Beatson, Dr. R. L. Bowles, Dr. R. Braithwaite, Dr. T. B. Crosby, Dr. T. Duka, Deputy Surgeon-General E. McKellar, and Professor J. Bell Pettigrew, M.D., F.R.S. Treasurer: Dr. T. Langston. Honorary Secretary: Dr. W. Rigden.

**MR. J. E. O'CONNOR, M.B., B.Ch. R.U.I., D.P.H. Camb.**, medical officer of health of Lowestoft, has been appointed medical officer of health of the combined districts of Leicestershire, Rutland, and Warwick. Dr. O'Connor is a captain in the Militia Medical Staff Corps and during the campaign in South Africa he acted as medical officer of health at Pretoria, being chosen by Earl Roberts for the post.

**HOW DISEASE IS SPREAD.**—At the Lawfords Gate Petty Session held on Nov. 28th, a woman, residing near Bristol, was summoned at the instance of the Barton Regis Rural District Council, for allowing her child to be on the highway whilst suffering from diphtheria. She had been advised to let the child go to the isolation hospital, but had refused to do so. The clerk to the council said that there had been 140 cases of diphtheria in the district. The defendant was ordered to pay a fine of 5s. with 50s. costs.

**ROYAL BRITISH NURSES' ASSOCIATION.**—The fourteenth annual conversazione of the Royal British Nurses' Association was held on Dec. 3rd at the Kensington Town Hall, when the guests were received by Miss Thorold, Mrs. Coster, Sir J. Crichton Browne, Mr. T. Pickering Pick, Mr. J. Langton, and Mr. Fardon. There was an excellent vocal and instrumental entertainment. The association, which was founded in 1887, has now a fund for the establishment of a settlement for nurses to live in, rent free, after they are too old to work. Small pensions are also granted. A bazaar in aid of the settlement building fund will be held on Feb. 6th and 7th, at 24, Park-lane, W., when Princess Christian has promised to open the bazaar and to preside at one of the stalls.

## BOOKS, ETC., RECEIVED.

ARNOLD, EDWARD, 37, Bedford-street, Strand, W.C.

A Text-book of Zoology. By G. P. Mudge, A.R.C.Sc. Lond., F.Z.S. Price 7s. 6d.

BOYER, L., 15, Rue Racine, Paris.

Vade-mecum d'Obstétrique et Gynécologie des Médecins-Praticiens. By Dr. Henri Fischer. Price 4 fr. 50.

CHURCHILL, J. & A., 7, Great Marlborough-street, W.

Transactions of the Ophthalmological Society of the United Kingdom. Vol. xxi., Session 1900-1901. With List of Officers, Members, &c. Price 12s. 6d.

Elementary Ophthalmic Optics, including Ophthalmoscopy and Retinoscopy. By J. Herbert Parsons, B.S., B.Sc., F.R.C.S., Curator, Royal London (Moorfields) Ophthalmic Hospital. Price 6s. 6d.

GEORGE NEWNES, Southampton-street, Strand, W.C.

The First Men in the Moon. By H. G. Wells, Author of "Tales of Space and Time," "Love and Mr. Lewisham," &c. Price 6s.

GRIFFIN, CHARLES, AND COMPANY, LIMITED, Exeter-street, Strand, W.C.

Year-book of the Scientific and Learned Societies of Great Britain and Ireland, comprising Lists of Papers read from January, 1900, to June, 1901. Price 7s. 6d.

JOHN BALE, SONS, AND DANIELSSON, Limited, 83, Great Titchfield street, W.

Bale's Dental Surgeon's Daily Diary and Appointment Book, 1902. Price 7s. plain; 8s. 6d. interleaved with ruled or blotting paper.

KNOWLEDGE OFFICE, 326, High Holborn, W.C.

Knowledge Diary and Scientific Handbook for 1902. Price 3s. net.

MURRAY, JOHN, Albemarle-street, W.

The Descent of Man and Selection in Relation to Sex. By Charles Darwin, M.A., F.R.S. New edition. Price 2s. 6d. net.

The Origin of Species by means of Natural Selection, or the Preservation of Favoured Races in the Struggle for Life. By Charles Darwin, M.A., LL.D., F.R.S. Popular impression of the corrected copyright edition, issued with the approval of the author's Executors. Price 1s. net.

SCIENTIFIC PRESS, LIMITED, 28 and 29, Southampton-street, W.C.

Syllabus of Lectures to Nurses. By Andrew Davidson, M.D., Port Health Officer, Singapore, late of Dorset Asylum. Price 1s.

## Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ACLAND, H. T. D., L.R.C.P., M.R.C.S., has been appointed Junior Obstetric House Physician at St. Thomas's Hospital.

BIRKBECK, L. H. C., B.A., M.B., B.Ch. Oxon., has been appointed House Physician at St. Thomas's Hospital.

BOWDLER, A. P., B.A. Cantab., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant to the Throat Department at St. Thomas's Hospital.

CHILD, F. J., M.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S., has been appointed Assistant House Surgeon at St. Thomas's Hospital.

CHOYCE, CHARLES C., M.B., Ch.B. Edin., B.Sc. New Zealand, has been appointed House Physician to the Leicester Infirmary.

CLARKSON, F., M.B., B.S. Durh., has been appointed Clinical Assistant to the Skin Department at St. Thomas's Hospital; also Clinical Assistant to the Ear Department.

DOWNES, T. W. H., L.R.C.P., M.R.C.S., has been appointed Assistant House Surgeon at St. Thomas's Hospital.

DUDGEON, L. S., M.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Electrical Department at St. Thomas's Hospital.

DUNCAN, ANDREW, M.D., B.S. Lond., M.R.C.P., F.R.C.S., has been appointed Physician to the Westminster Dispensary.

GLANVILLE, W. M. G., B.A., M.B., B.Ch. Oxon., has been appointed House Physician at St. Thomas's Hospital.

GOUGH, H. E., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer of Health for the Rural District of Northwich.

GRIMWADE, A. S., L.R.C.P., M.R.C.S., has been appointed House Surgeon at St. Thomas's Hospital.

HAMILTON, A. D., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant to the Throat Department at St. Thomas's Hospital.

HARVEY, FRANK, M.R.C.S., L.S.A., has been appointed Medical Officer of Health for Padstow, Cornwall.

HENDERSON, T. B., M.A., M.B., B.Ch. Oxon., has been appointed Assistant House Physician at St. Thomas's Hospital.

HILL, W., B.A. Cantab., L.R.C.P., M.R.C.S., has been appointed Assistant House Surgeon at St. Thomas's Hospital.

HODSON, V. S., B.A., M.B., B.Ch. Oxon., has been appointed House Physician at St. Thomas's Hospital.

HUNT, S., L.R.C.P., M.R.C.S., has been appointed House Surgeon at St. Thomas's Hospital.

LOW, V. WARREN, F.R.C.S., has been appointed Surgeon to Out-patients at the Great Northern Central Hospital, Holloway-road, N.

MARR, H. C., M.D. Glasg., has been appointed Medical Superintendent at Woodilee Lunatic Asylum, Lenzie, vice Dr. Robert Blair.

MENNELL, Z., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed Senior Obstetric House Physician at St. Thomas's Hospital.

NITCH, C. A. R., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed House Surgeon at St. Thomas's Hospital.

O'CONNOR, J. E., M.B., B.S., R.U.I., D.P.H. Camb., has been appointed Medical Officer of Health for the combined districts of Leicestershire, Rutland, and Warwick.

PARRY, LEONARD A., F.R.C.S. Eng., B.S., M.D. Lond., has been appointed Assistant Surgeon to the Royal Alexandra Hospital for Children, Brighton, vice Mr. T. H. Ionides, resigned.

PATERSON, T. W. S., M.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S., has been appointed House Physician at St. Thomas's Hospital.

SHIPMAN, G. A. C., M.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S., has been appointed Assistant House Surgeon at St. Thomas's Hospital.

SINCLAIR, NORMAN J., M.B., Ch.B. Aberd., has been appointed Medical Officer of Health and Police Surgeon for the Burgh of Brechin.

STANNUS, H. S., L.R.C.P., M.R.C.S., has been appointed Assistant House Physician at St. Thomas's Hospital.

SPOKES, H. FRASER, M.D., has been appointed Medical Officer to the Highbury Truant School of the London School Board.

THOMSON, B., M.B. Glasg., has been appointed Assistant Medical Officer of the Holborn Infirmary at Highgate.

TIMMINS, J. L., M.A., B.C. Cantab., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant to the Skin Department at St. Thomas's Hospital.

WOODS, W. H. O., B.A., M.B., B.C. Cantab., has been appointed House Surgeon at St. Thomas's Hospital.

WYNTER, WALTER ESSEX, M.D., B.S., F.R.C.S., F.R.C.P., has been appointed Physician to the Middlesex Hospital.

## Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index).*

BETHLEM HOSPITAL.—Two Resident House Physicians for six months. Honorarium at rate of £25 each per quarter, with board and washing.

BRADFORD ROYAL INFIRMARY.—Dispensary Surgeon, unmarried. Salary £100 per annum, with board and residence.

BURGH OF PAISLEY INFECTIOUS DISEASES HOSPITAL.—Resident Physician. Salary £100 per annum, with board, washing, and attendance.

COUNTY ASYLUM, Rainhill, near Liverpool.—Assistant Medical Officer, unmarried. Salary £150 per annum, with prospect of increase, and apartments, board, attendance, and washing.

DEVONSHIRE HOSPITAL, Buxton, Derbyshire.—House Surgeon and Assistant House Surgeon. Salary, House Surgeon £100 per annum, Assistant £50 per annum, with apartments, board, and lodging.

DOWN DISTRICT LUNATIC ASYLUM, Downpatrick.—Assistant Medical Officer, unmarried. Salary £150, increasing to £200, with apartments, board, washing, and attendance.

GREAT NORTHERN CENTRAL HOSPITAL.—Assistant House Surgeon for six months. Salary at the rate of £30 per annum, and board.

LINCOLN COUNTY HOSPITAL.—Junior House Surgeon for six months, eligible for re-election. Honorarium of £25 for each period of six months, and board, residence, and washing.

MIDDLESEX HOSPITAL, W.—Assistant Physician.

NOTTINGHAM GENERAL HOSPITAL.—House Surgeon. Salary £100, rising to £120, with board, lodging, and washing.

QUEEN'S JUBILEE HOSPITAL.—Two Surgeons and Physicians, also Ophthalmic Surgeon.

ROCHDALE INFIRMARY.—Resident Medical Officer, unmarried. Salary £100 per annum, with board, residence, and washing.

ROYAL SURREY COUNTY HOSPITAL, Guildford.—Resident House Surgeon. Salary £100. Also Assistant House Surgeon. Salary £75, both with board, residence, and laundry.

ST. MARY'S HOSPITAL MEDICAL SCHOOL, Paddington, W.—Obstetric Tutor.

STAFFORDSHIRE GENERAL INFIRMARY, Stafford.—House Surgeon. Salary £120 per annum, with board, lodging, and washing.

SWANSEA GENERAL AND EYE HOSPITAL.—Resident Medical Officer. Salary £75 per annum, with board, apartments, washing, and attendance.

TOTTENHAM HOSPITAL.—House Surgeon. Salary £50 per annum, with board, residence, laundry, &c.

WESTERN GENERAL DISPENSARY, Marylebone-road, N.W.—Second House Surgeon, unmarried. Salary £80 a year, with board, residence, and laundry.

WEST HAM HOSPITAL, Stratford, E.—Junior House Surgeon for six months, renewable. Salary £75 per annum, with board, residence, &c.

WESTMINSTER GENERAL DISPENSARY.—Resident Medical Officer. Also Honorary Surgeon.

WORCESTER COUNTY AND CITY ASYLUM.—Junior Assistant Medical Officer. Salary £120, rising to £150, with board, apartments, and washing.

## Births, Marriages, and Deaths.

### BIRTHS.

BENHAM.—On Nov. 26th, the wife of Charles H. Benham, M.D. Lond., of a daughter.

DRAKE.—On Nov. 28th, the wife of Courtenay H. Drake, F.R.C.S., of a son.

MILLS.—On Nov. 30th, at Cookham, the wife of Frederick Andrew Mills, B.A., M.B., B.C. Cantab., of a daughter.

POTTS.—On Nov. 27th, at Birmingham, the wife of W. A. Potts, M.D. Edin., of a son.

### MARRIAGES.

GENGE—WHEELDON.—On Nov. 28th, George Gilbert Genge, M.D., B.S. Lond., to Catherine, second daughter of the late George Wheeldon.

JONES—DIXON.—On Nov. 23th, Robert Orford Jones, L.R.C.P. Edin., L.R.C.S. Edin., to Mrs. Ellen Flower Dixon.

PROWSE—FORD.—On Nov. 28th, William Barrington Prowse, M.R.C.S., L.R.C.P. Lond., to Mabel, youngest daughter of the late William Barton Ford.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

## Notes, Short Comments, and Answers to Correspondents.

### STILL THE CHEAP PISTOL.

PISTOL tragedies are now almost weekly occurrences and we need hardly notice those which do not end fatally for anyone. This time it is a gas-stoker in Lambeth who, after duly threatening his victim in a letter with something that he kept in his pocket, proceeded to her house, shot her, and then shot himself. The girl at the time of writing is still alive; the man is dead. Further comment is not needed. On the day of the Lambeth tragedy referred to a hawker was arrested for being drunk and assaulting another man on the top of an omnibus by striking him on the head with a revolver, which turned out to be loaded in all its six chambers; but as the revolver did not go off, and consequently no one was killed, the matter is perhaps too trivial to be worthy of notice. The death of the mayor of a provincial town in France by a revolver shot fired in a scrimmage in the municipal chamber was reported in the newspapers on the same date (Nov. 26th) as the two other matters to which we have alluded, but it has no direct bearing on the question of cheap revolvers sold without inquiry to any customer, as presumably the restrictions we wish to see imposed, even had they existed. France, would hardly have prevented a borough councillor from acquiring his weapon. The incident, however, points to the increased and increasing extent to which pistols are carried by apparently peaceful and respectable persons in peaceful and civilised countries.

### FRIENDLY SOCIETIES AND THEIR MEDICAL AID INSTITUTIONS.

To the Editors of THE LANCET.

SIRS,—The almost contemptuous patronage of the profession by your correspondent in THE LANCET of Nov. 30th, p. 1554, on the subject of friendly society medical aid associations would be very amusing if it [were] not offensive. Your correspondent boasts of the privileged position of these medical exploitation syndicates as compared with that of men practising in their own names. The fact that such as he should glory in our shame ought to be sufficient to infuse energy into the feeble medical backbone to enable us to sweep away once and for all this miserable pretence of justice and fair dealing. Plainly the method of practice is this—that a number of persons shall combine to employ a medical man for their own uses and at their own price, that they shall take the money subscribed and give him so little as they deem fitting, that he shall attend their confinement cases for 10s each, and extract their valuable teeth for a penny or for nothing, and that he shall sacrifice all independence to act as their professional hack, as their hired servant. The men who attempt to drive, and too often succeed, this hard bargain with the profession are not poor workmen. The British working man would be ashamed to treat a fellow workman in this scurvy fashion. The ringleaders of the system are men well able to pay a medical man decent fees. They obtain their cheap attendance by the sweating of the unfortunate practitioner who falls into their clutches and from the comparatively adequate payments of the poor. But the shabby fraud does not end here. If one conceded the point that it might be right to exploit the profession in this way, which I for one will not, it would still be evident that these very independent institutions should be self-supporting; but are they? Emphatically no! In cases of accident, of emergency, of serious operation, they fall back on the hospital and its honorary surgeons. If they adopt the system they should do it thoroughly and render themselves and their medical nominees independent of outside help. I contend that this practising by a syndicate or by a committee through a salaried servant, in the interest of men who cannot plead poverty as an excuse, is a species of covering, and that as such we ought to demand its suppression or strict regulation by the General Medical Council.

I am, Sirs, yours faithfully,

Loughborough, Nov. 30th, 1901. J. B. PIKE.

### THE OUTBREAK OF INFLUENZA IN 1742.

In the *Yorkshire Herald* passages are being occasionally reproduced from the *York Courant*, a well-known paper in the eighteenth century, and a recent extract bearing the date 1742 has a distinct medical interest. "By private letters from Rome," says the *York Courant* 160 years ago, "we have a very melancholy Account of the surprising Progress an Epidemical Distemper called the Influenza, makes there; that in one day 500 persons were carried to their Grave by it; that scarce a Noble Family in that City had not lost some person; and Hearses, Coffins, and the Host carrying to the Sick were to be met with in all the streets. They observe that this distemper began in Saxony last September, had visited Venice, Genoa, Milan, and Florence, in the latter it still continued; that it had reached the city of Naples, but had not made much Havoc; that the Venetians had begun a Land Quarantine; and that it was expected the Sea Coasts of other Countries would do the same. Though not in itself a plague, the Physicians of those parts reckon it a Forerunner."

### DIFFERENTIAL DIAGNOSIS BETWEEN SMALL-POX AND CHICKEN-POX.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Oct. 12th, p. 1007, there appeared a letter on the above subject, and I agree with the writer, Dr. G. S. Perkins, that the point noted by him furnishes us with one of the most reliable means of distinguishing the two diseases. What I wish to call attention to, however, is that, although undoubtedly the severity of the chicken-pox rash on the face is, as a rule, nothing compared to that of small-pox, yet exceptions do occur. In Fagge's "Medicine" (second edition, vol. i., page 245) one reads: "Formerly it [the eruption of varicella] was said to spare the face; and although this is incorrect it certainly does not come out more thickly there than elsewhere, as is the case with variola." In the beginning of September last I was called to see a boy whose parents were afraid that he had developed small-pox, as they had recently returned from Glasgow. When I saw the patient I rapidly diagnosed chicken-pox, and this in spite of the fact that his face and ears were literally covered with vesicles and there was little eruption elsewhere. I had many points of difference to go upon, but the pricking of a few of the vesicles was decisive.

I am, Sirs, yours faithfully,

Dec. 3rd, 1901.

VARICELLA.

P.S.—The diagnosis in this case was clear enough; what I wish to emphasise is the peculiar distribution of the exanthem.

### DOUBTFUL COMPLIMENTS.

To the Editors of THE LANCET.

SIRS,—Have you not missed a point in dealing with the matter of Dr. Lunn's complimentary tickets to medical men? I have made inquiries and I doubt if the real position of Dr. Lunn's firm in the matter is quite clear in your columns. Let me take the case of a trip to Rome to illustrate my meaning. The complimentary 1st class return ticket to Rome is £16 1s. 8d., instead of £17 17s. Do the recipients of these complimentary tickets know how much they cost Dr. Lunn's firm? Just £10 18s. 3d. They are certainly "society" tickets, available only on fixed days, and the price of these tickets is, I am credibly informed, £10 18s. 3d. Dr. Lunn puts down the expenses of seven days' *en pension* in Rome at £3 5s. Accepting his figures, if we add £3 5s. to £10 18s. 3d. we have a total of £14 3s. 3d. £14 3s. 3d. is the cost to Dr. Lunn's firm of the complimentary ticket, for which the receiver of the compliment pays £16 1s. 8d. as a favour, being expected to return the favour by lauding the methods of the firm.

I am, Sirs, yours faithfully,

Kensington, Dec. 4th, 1901.

M.B.

### A SUGGESTION FOR TREATMENT.

To the Editors of THE LANCET.

SIRS,—In reply to "M.B. Lond." in THE LANCET of Nov. 30th, p. 1554, I would recommend the following treatment: one drachm of tincture of lobelia, one drachm of tincture of stramonium, 20 minims of tincture of belladonna, two minims of glycerine of carbolic acid, and distilled water to two ounces. Filter. Place a tablespoonful of the above mixture in Burroughs and Wellcome's "Paroline ointment atomiser" and let the patient forcibly inhale three or four puffs of the spray through the nostril well down into the bronchi. This will cut short an attack if used early. Will "M.B. Lond." please report result?

I am, Sirs, yours faithfully,

Montreux, Dec. 1st, 1901.

TUCKER WISE.

### MESCAL INTOXICATION.

In THE LANCET of June 5th, 1897, p. 1540, Mr. Havelock Ellis gave a lengthy account of his personal experiences of the vision-producing properties of the mescal button (the fruit of the anhalonium Lewinii). These buttons, he says, are eaten by the Kiowa and other Indians of New Mexico, and their use is connected with religious ceremonial. In his experiments Mr. Ellis cut up three buttons (a full dose) into small fragments, poured boiling water on them twice, and took this infusion in three portions at intervals of an hour. His conclusions were that "the phenomena of mescal intoxication are thus mainly a saturnalia of the specific senses and chiefly an orgy of vision." Mr. Ellis makes no mention of mescal products being in extensive popular use as an alcoholic intoxicant, but it is known that some species of agave (agave Americana, agave Mexicana, agave pulque) supply such beverages. Several of the species have a resemblance to plants of the genus aloe, with which they are sometimes confounded. Agave Americana (the so-called American aloe or century-plant, one of the maguays of South America, the mescal of Mexico), when it has reached maturity, which takes from 10 to 70 years according to the climate, sends out a stem 40 feet high surmounted by a panicle of yellow flowers. A writer in the *Echo* of Nov. 25th states that the use of agave products as alcoholic intoxicants is having a deplorable effect on the Mexican people. Pulque, he says, is made by diluting the sweet paste of the agave juice with water and leaving it for five days to ferment, but a far more deadly drink is mescal, which is distilled from the juice of a plant also belonging to the natural order amaryllidaceae, but very different from the ordinary pulque-producing agave. It is called in popular parlance the maguey and grows wild in abundance. The leaves are collected from the ripe maguey plants and carried by donkeys and mules to

a rude oven, where they are roasted for two days and then put into the vats to rot and to ferment. After being well rotted they are taken out and mashed and put into the still, an apparatus of primitive construction, from which the condensed vapour trickles out in a colourless stream, and is then redistilled. It is now put up in kegs, oval-shaped and flat on the sides, almost two feet high, and a foot and a half wide across the broadest part. Among the greater part of the community in Mexico no social entertainment is complete without copious draughts of mescal. To its use can be traced 90 per cent. of all the crimes perpetrated in the ranches and villages.

#### ADMINISTRATION OF ETHER TO YOUNG CHILDREN.

To the Editors of THE LANCET.

SIR,—From time to time it has fallen to my lot to see infants and young children being inverted, artificially respired, and otherwise stimulated in order to bring them out of a state of collapse due to the inhalation of chloroform. On my inquiry of the administrator why he did not use ether I am nearly always informed that young children either will not take ether at all or that they take it very badly. This is so contrary to my experience that I wish to draw attention to the fact that ether, given alone or with nitrous oxide, is an admirable anæsthetic for young children, always provided that plenty of air is given at the same time. I use the ordinary Clover inhaler with a small facepiece. After a few preliminary breaths of nitrous oxide the indicator is gradually turned on to about the No. 3 and the bag is removed, the child inspiring and expiring through the open inhaler and so getting a free supply of fresh air. If nitrous oxide is not available the inhaler is used without the bag from the start, the indicator worked up to "Full" in from three to five minutes, and when anæsthesia is complete moved back to near the number three. *Cæteris paribus*, the younger the child the quicker the anæsthesia and the smaller amount of ether required. The only drawback is the somewhat large amount of ether used. This might be obviated by having inspiratory and expiratory valves on the facepiece.

In regard to the old controversy of ether *versus* chloroform the conviction is gradually being forced upon me that a large number of the advocates of chloroform, in preferring chloroform, omit to state the real reason for their preference, which is simply that they do not know how to administer ether. The value of such testimony is obvious. A surgeon once described to me a ridiculous scene at which he had been assisting in which a practitioner, armed with the latest form of gas-and-ether inhaler, had totally failed to anæsthetise the patient, who at the end of half an hour was wide awake. I can quite understand such an administrator being a strong advocate of chloroform and an equally strong opponent of ether. The following are examples of cases in which during the past nine months I have used ether or nitrous oxide and ether for young children under six years of age, the limit within which chloroform is often supposed to be the best, if not the only, anæsthetic:—

Anæsthetic.	Age of patient.	Nature of operation.	Duration of administration.
Nitrous oxide and ether.	4 years.	Amputation of toe.	30 minutes.
ditto.	4 years.	Necrosis of lower jaw.	20 minutes.
ditto.	4 years.	Brasion of knee-joint.	50 minutes.
ditto.	3 years.	Radical operation for inguinal hernia.	30 minutes.
ditto.	2 years.	Abscess of groin.	15 minutes.
ditto.	11 months.	Scraping tubercular finger.	10 minutes.
Ether.	6 months.	Cauterising nevus.	10 minutes.

I am, Sirs, yours faithfully,

C. HAMILTON WHITEFORD,

Senior Anæsthetist, South Devon and East Cornwall Hospital.  
Plymouth, Nov. 29th, 1901.

#### THE CASE OF THE LATE MR. W. K. BROCK.

IN THE LANCET of Nov. 16th, p. 1387, we published an appeal for contributions to a fund on behalf of the family of the late Mr. W. K. Brock, M.R.C.S., L.S.A., L.M. (formerly in the A.M.S. but obliged to leave the service on reduction of staff), whose untimely death, owing to an accident, left in very straitened circumstances a widow and eight children. It was pointed out that it was specially urgent to collect a sum on behalf of one of these children to enable him to obtain a living for himself and eventually to help the rest of the family. The appeal was signed by George Dunlop, The Vicarage Knowle, Bristol; E. H. C. Pauli, M.R.C.S. Eng., L.R.C.P. Lond., Alma Villa, Wells-road, Knowle, Bristol; Charles Steele, M.D. Durh., F.R.C.S. Eng., Clifton Villa, Clifton, Bristol; and James Stewart, B.A. R.U.I., F.R.C.P. Edin., Dunmurry, Sneyd-park, Clifton, Bristol. This appeal has, we understand, not received the support which it deserves. The secretary states that it was hoped to receive at least £25 before Christmas, but up to the present the total does not reach much more than half that amount. As the money is being raised to

save a family from actual starvation it is hoped that this renewed appeal may not be in vain. Subscriptions will be gratefully acknowledged by Mr. B. Jones, Balcarras, Wells-road, Knowle, Bristol, and cheques should be drawn in favour of the honorary treasurer, Mr. E. H. C. Pauli, and crossed "Lloyd's Bank, Limited, Temple-gate, Bristol Branch (Brock Fund)."

T. W. B. acted correctly, as it was completely impossible, in the circumstances, to swear that the vulvo-vaginitis was of gonorrhœal origin. The medical witness could only testify to what he knew, and it would have been entirely wrong of him to back up other circumstantial evidence by stretching his own evidence to a point where science would not have endorsed him. The solicitor for the prosecution, who described "T. W. B.'s" properly restrained and accurate scientific evidence as "weak," appears not to have cared much what was said so long as a conviction was secured. This attitude is not an uncommon one, but we do not regard it with much respect.

M. D., who expresses the hope that we shall "be able to give a satisfactory reply," has omitted to inclose the card to which he alludes. Our reply, however, is that what we said in our leading article is our belief and the belief of most sensible persons. A certain class of humanitarians appear to think that a large section of the community are the victims of flagellomania, a pathological condition which, in our experience, very few medical men have ever witnessed.

R. G. and R. P.—We do not give medical advice. Both matters can be adequately dealt with by the usual medical adviser.

A. M. F.'s letter has been forwarded to the writer of the inquiry.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

#### METEOROLOGICAL READINGS.

Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square, (9.30 A.M.), City Orthopedic (2.30 P.M.).  
**SATURDAY (14th).**—Royal Free (9 A.M. and 2 P.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.), Throat, Golden-square (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

## SOCIETIES.

**MONDAY (9th).**—MEDICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—8.30 P.M. Dr. A. Crombie: The Physical Disabilities for Tropical Life.—Dr. J. Anderson: The Remote Effects of Tropical Life on Europeans.

**TUESDAY (10th).**—PHARMACEUTICAL SOCIETY OF GREAT BRITAIN (17, Bloomsbury-square, W.C.).—8 P.M. Communications from the Research Laboratory:—Prof. Greenish and Mr. Upsher Smith: Tincture of Nux Vomica.—Prof. Greenish: The Official Test for Myrrh. Papers:—Mr. E. M. Holmes: (1) Note on Pure Otto of Rose; (2) Note on the Official Test for Strophanthus Kombe.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Address: Dr. S. M. Copeman: Modern Methods of Vaccination and their Scientific Basis (illustrated by lantern slides and followed by a discussion).

**WEDNESDAY (11th).**—DERMATOLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—5.15 P.M. Demonstration of Cases of Interest.

SOUTH-WEST LONDON MEDICAL SOCIETY (Bolingbroke Hospital).—Paper:—Dr. A. E. Giles: Diagnosis of Pelvic Tumours.

**THURSDAY (12th).**—CHILDHOOD SOCIETY (Library of the Sanitary Institute, Margaret-street, W.).—8 P.M. Lecture.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos-street, Cavendish-square, W.).—Clinical Evening. Cases will be shown by Mr. H. W. Dodd, Mr. H. Juler, Mr. B. T. Collins, Mr. E. Stephenson, Mr. G. B. James, Mr. G. Keeling, Mr. J. B. Lawford, Mr. G. W. Roll, Mr. J. H. Fisher, and Mr. L. V. Cargill.

BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover-square, W.).—8 P.M. Specimens will be shown. Paper:—Mr. S. Bishop: A Demonstration of some Changes observed in Uteri the Seat of Fibromyomata.

**FRIDAY (13th).**—CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Papers:—Dr. Habershon: The association of Moveable Kidney on the Right Side with Symptoms of Hepatic Disturbance.—Dr. S. Wilson: The Theory of Compensation in Disease of the Mitral Valve.—Dr. W. H. White and Dr. W. O. Pakes: A Case of Malignant Endocarditis giving Widal's Reaction.—Mr. E. P. Paton: A Case of Hair Ball removed from the Stomach of a Child nine years.

EPIDEMIOLOGICAL SOCIETY (11, Chandos-street, Cavendish-square, W.).—8.30 P.M. Paper:—Dr. Mott: Dysentery in Asylums.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &amp;c.

**MONDAY (9th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Dr. J. J. Pringle: Clinique. (Skin.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Paget: Empyema.

**TUESDAY (10th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Dr. G. Rankin: Clinique. (Medical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Bidwell: Nephrorrhaphy and its Results.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury).—3.30 P.M. Mr. Ballance: Surgery of the Nervous System.

**WEDNESDAY (11th).**—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Mr. T. R. Jessop: Personal Experiences in the Surgical Treatment of Certain Diseases. (Bradshaw Lecture.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Mr. J. Smith: Clinique. (Surgical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Eccles: Surgical Anatomy.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. H. Mackenzie: Pleurisy with Effusion.

**THURSDAY (12th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Mr. Hutchinson: Clinique. (Surgical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Robinson: Uterine Hemorrhage.

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Mr. Lister: Demonstration of Ophthalmic Cases.

CHARING-CROSS HOSPITAL.—4 P.M. Mr. M. Murray: Medical Cases. (Post-Graduate Course.)

**FRIDAY (13th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Dr. D. Grant: Clinique. (Bar.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. S. Taylor: Medical Anatomy.

During the week marked copies of the following newspapers have been received:—Kiddermington Shuttle, Macclesfield Advertiser, Sussex Daily News, Wills County Express, Glasgow Times, Portsmouth Evening News, Cardiff News, Bridge of Allan Reporter, North Guardian, Glasgow Herald, East Anglian Times, Coventry Telegraph, Gazette des Hôpitaux (Paris), Evening Standard, Westminster Gazette, Morning Advertiser, Standard, Daily Express, Aberdeen Weekly Press, Surrey Advertiser, Leeds and Yorkshire

Mercury, Municipal Reformer, Allgemeine Medicinische Central-Zeitung, Revista Medica de San Paulo, Liverpool Daily Post, Windsor and Eton Express, Reading Mercury, La Caducée, Hong-Kong Weekly Press, Times of India, Pharmaceutical Journal, Dublin Evening Telegraph, Southampton Echo, Stafford Advertiser, &c.

## EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Lectures, original articles, and reports should be written on one side of the paper only. AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising, departments of THE LANCET should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

## TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsgents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently, inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

# The Bradshaw Lecture

ON

## PERSONAL EXPERIENCES IN THE SURGICAL TREATMENT OF CERTAIN DISEASES.

*Delivered at the Royal College of Surgeons of England on Dec. 11th, 1901,*

By T. R. JESSOP, F.R.C.S. ENG.,  
VICE-PRESIDENT OF THE COLLEGE.

MR. PRESIDENT AND GENTLEMEN,—Permit me, before commencing my address, to express to you, however inadequately, my deep sense, shared, I am sure, by everyone here present, of the enormous loss our profession and the entire community have sustained in the death of our late President, Sir William MacCormac. The whole world knows how, at the call of the Government, he faced the dangers of the South African battlefields in order to place his unrivalled experience at his country's service, at a time, too, when he might well have claimed his right to rest. Who can estimate the sum of consolation carried by this act of patriotism into the innumerable anxious homes throughout the length and breadth of the land? We alone who have been brought into close contact with him within these walls can appraise the value of his work on behalf of this College. No man has had its interests more at heart, none been more ready to place time and labour at its disposal. To us it is a consolation to know that he has died honoured alike by his Sovereign, his professional brethren, and the people.

The generous Founder of the Bradshaw Lecture exercised, I think, a wise discretion in permitting each individual lecturer to select his own subject, placing no further restriction upon him than that he shall not range beyond the realm of surgery. Such liberty of choice would seem admirably calculated to afford opportunities for the appointed lecturers to place before their colleagues matured opinions upon subjects in which they may have been specially interested or may perchance have obtained wide, if not exceptional, experience. Our late distinguished President, when asking me to undertake the task for this year, must chiefly, I feel sure, have intended to do honour to the large and well-reputed hospital with which I have for many years been connected, and yet, whilst fully recognising this, I desire to place on record my high appreciation of the compliment paid to myself. A hospital surgeon, engaged as I have been in active surgical work for a period of more than 30 years, cannot fail to have observed facts, to have made deductions, and to have formed opinions from which perchance some advantage may accrue to those who follow after. It is in the hope that my own experiences may prove helpful to others in however small a degree that I have determined to speak to you to-day upon some lessons which I have learned in the surgical treatment of certain organs. Within the limits of a single lecture it would of course be impossible adequately to deal with the surgical affections of even a single organ or region, and it is not my intention to make so vain an attempt. My desire is rather to illustrate from the records of my own practice some well-known surgical diseases and to indicate the methods of dealing with them which have commended themselves to my judgment.

I have hesitated somewhat in my desire to say something concerning the surgery of the kidney, our colleague, Mr. Morris, having recently published so complete and masterly a work on this subject as to leave little unsaid. On most questions, however, and especially on those of recent origin and development, there is room for personal experience, even if the outcome be no more than to confirm what has been observed by others; nay, more, it is only by the accumulated experience of many that such works as Morris's are rendered possible, and so it becomes a duty for each of us to make what addition we can to the common stock. I will not therefore apologise for offering my small contribution to so large a subject, but will claim that in so doing "I've done my duty and I've done no more."

My first essay in renal surgery dates back to the winter of 1869-70, and as it exhibits a combination of boldness with

timidity which not inaptly exemplifies the surgery of that date I will not hesitate to make confession of it. It was about this time that M. Dieulafoy had introduced to the profession his well-known "pneumatic aspirator," an instrument which early came into very general use, and by means of which surgeons were emboldened to evacuate and to examine the contents of cavities and swellings hitherto most frequently reserved for post-mortem examination alone. Few diagnoses, indeed, were considered complete which did not include the information to be obtained by means of this instrument. A dispensary patient, pale and emaciated from a long-standing pyuria, was brought under my notice in whose right loin could be plainly felt a large swelling, firm, fixed, and elastic. A diagnosis of abscess in the kidney was confirmed by an obvious diminution in the urinary sediment after several ounces of pus had been evacuated through the loin by means of the aspirator needle. The suppuration along the needle track which ensued led me to incise freely the loin and the subjacent kidney, the dilated calices of which were readily felt by the finger introduced through the incision. No foreign substance was felt nor was any diligent search made. The after-treatment consisted of the inevitable linseed poultice, and the results, I need hardly say, were pyæmia and death. In addition to the pyæmic foci of recent origin the necropsy revealed nothing more than a kidney converted into a thick-walled sacculated bag of pus in which was embedded a phosphatic coated uric acid calculus of considerable size. Of the early history of this patient I have neither note nor recollection. Probably it was less eventful than the extent of mischief would seem to imply. The result warned me off the kidney and increased the superstitious dread which I shared with the profession at large of meddling with so vital an organ. These, too, were the pre-antiseptic days, for although Lister had been labouring hard for some years to secure the acceptance of his doctrines respecting the origin, causation, and prevention of surgical inflammation, it was not until about the year 1870 that he obtained anything like a general adhesion to his teaching; and it is not too much to say that had it not been for Lister's discoveries there would in all probability have been even now but little advance in renal surgery upon the sample I have just related. It was not, indeed, until late in the "seventies" that surgeons made any serious attempt to bring the kidney within the range of their treatment. Mr. Morris tells us that he was the first to undertake a nephro-lithotomy and his operation took place in February, 1880. Simon of Heidelberg is credited with having been the first intentionally to perform a planned nephrectomy in 1869; and in these early days Dr. Meadows and Mr. Durham in this country and others abroad have reported cases in which the operation was either completely or incompletely performed, albeit on a mistaken diagnosis.

In June, 1877, I undertook my first nephrectomy upon a child, aged two years and three months, who for several months had been passing bloody urine and whose condition was one of pallor with some wasting. In the left loin an increasing mass of considerable size, easily defined and possessing some slight degree of mobility, had been under observation during several weeks. The operation consisted of an incision in the loin commencing a finger's breadth from the vertebral spine and carried midway between the costal margin and the iliac crest to an extent sufficient to allow of the insertion of the fingers and thumb. On careful division of the muscles the capsulated tumour was exposed and its separation from surrounding tissues, together with that of the kidney from which it sprang, was easily effected. The whole of the pedicle, containing ureter and blood-vessels, was secured in a double ligature of hemp and the mass, severed from its pedicle by scissors, was removed. The growth, which involved a considerable portion of the renal structure, is described in the notes as "encephaloid." The immediate recovery of the child was complete and satisfactory, but the respite was not of long duration, inasmuch as during the ensuing autumn the child died with unequivocal signs of a return of the disease beneath the site of the operation. Owing to my absence from home the body was not examined. These details may be of some interest from the fact that this was, so far as I am aware, the first nephrectomy undertaken of set purpose in this country, and for the additional reason that the general outlines of the case as here given do not differ materially from those found in a large majority of the cases of sarcoma of the kidney in young children, of which this was probably an example. Eight similar cases have

come under my own observation in which, with variations only in age—the youngest being 13 months and the eldest five and a half years—in the size and the duration of the tumour and in the general condition of the patient the description I have given would apply equally. Nor have I in the later cases materially altered the mode of operation. The incision has been made somewhat nearer the last rib and has been lengthened when necessitated by the size of the tumour; silk ligatures have been substituted for the hemp, and greater care has been exercised in establishing and maintaining complete asepticity of the wound. One little patient died under operation from loss of blood and shock; the rest recovered from the effects of the operation.

Walsham in Morris's treatise on Anatomy points out the danger when performing nephrectomy on the right side of including within the ligature a portion of the vena cava. Once this actually occurred in my hands and on another occasion my previous experience alone enabled me to avoid a like catastrophe. The first of the two cases was that of a female, aged two years and 10 months, sent to me in June, 1883, in whose abdomen her father accidentally discovered a swelling at a time when the child was believed to be quite well. No deviation from health and not a symptom of any kind had been observed. Once attention had been drawn to the swelling it was closely watched and it soon became evident that a rapid increase was taking place. When brought under my notice the right half of the abdomen was occupied by a smooth, firm mass, equal in size to a foetal head at birth, which moved visibly during respiration and admitted of a considerable amount of lateral displacement (and I may remark parenthetically here that unusual mobility due to, or at least attended with, an elongated pedicle was a marked feature in both cases). In accordance with my practice at that time—a practice which I have long since abandoned as an aid to the diagnosis of any abdominal tumour—an aspirator needle was introduced with the result that the withdrawal of a minute quantity of blood only determined the solid character of the growth. It was then decided to remove it and the operation was performed at the patient's home. Owing to the entire absence of symptoms, the extreme mobility of the mass, and our inability to attach it to any organ no diagnosis was arrived at. An incision was made through the linea alba in mid-abdomen and the tumour with cæcum and ascending colon pushed across to the left of the vertebral column exposed. On inspection it was seen to consist of a growth springing from the kidney and tethered by a broad pedicle, containing the renal vessels and the ureter, to the loin so loosely as to allow a free range of movement. Through an incision made in the external layer of the meso-colon the peritoneum was stripped and the mass was delivered with more readiness than was expected owing to the length of the pedicle. This was transfixed and tied with a double silk ligature. The kidney and tumour, weighing together three pounds and two ounces, were detached by means of scissors. The peritoneal incision was sutured and the cavity drained by a rubber tube passed through the loin. The operation lasted one and a quarter hours. Five hours after its completion the temperature was found to be 101° F. and the pulse was of good volume. The child was cheerful and chatted freely with her nurses. Two hours later—viz., seven hours after the operation—the patient died with absolute suddenness. A subsequent examination of the growth—there was no post-mortem examination—threw some light on the cause of death, seeing that in the portion of the pedicle removed it was found that the enlarged renal vein abruptly widened out so enormously where ligatured as to suggest that the vena cava had been dragged by the weight of the mass of disease so as to project well within the root of the kidney. (Fig. 1.)

In removing the kidney for malignant disease the surgeon, naturally anxious to avoid leaving a portion of the disease behind, secures the vessels at as great a distance as possible from the kidney. In avoiding this danger it is well to bear in mind another, that, viz., of including within the grip of the ligature a portion of the wall of the vena cava, and so incurring the risk of the formation of a thrombus, which at any moment may be washed into the right heart and give rise to sudden death.

The second case was that of a child, two years old, admitted into the Leeds Infirmary in October, 1888, in whom the right kidney was the seat of a cystic sarcoma forming a large tumour which filled the right half of the abdomen and extended beyond the mid-line. This, like the former,

admitted of a considerable range of lateral movement, but, unlike it, was not visibly affected by respiration. It was removed by the abdominal route, the incision being made to follow the course of the outer right linea semilunaris. After incising the peritoneal covering and stripping the mass from its surroundings it was found, as in the former case, that owing to the length of its pedicle it could readily be withdrawn from the abdominal cavity; and on closely examining the pedicle there was no difficulty in demonstrating the vena cava as one of its constituents; it occupied, indeed, so much of the meso-nephron as to necessitate special care in the selection of the spot at which to place the ligature. The

FIG. 1.

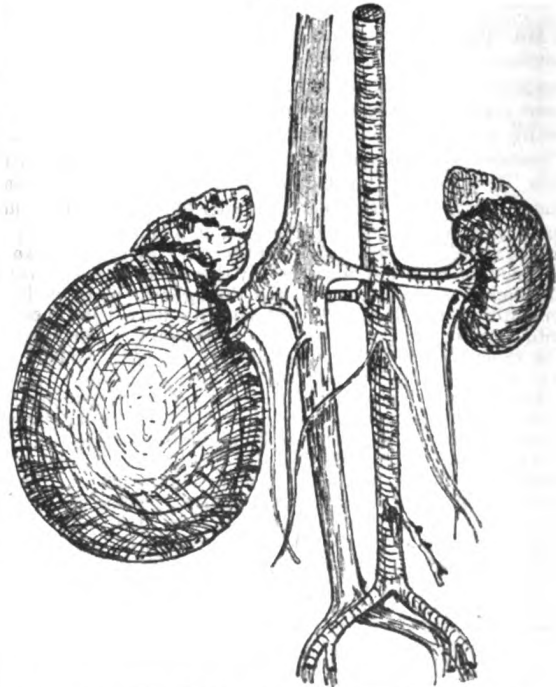

Diagram illustrating the effects of a large tumour of the right kidney producing great dilatation of the renal vein and lateral displacement of the vena cava.

visceral peritoneum was closed by a continuous suture except at its lower end, where it was attached to the inferior extremity of the abdominal wound for drainage purposes. The patient recovered and was sent home in December; but in the February following the medical attendant wrote to say that the child died on the 7th of that month.

It will thus be seen that of the 11 cases of nephrectomy for tumour in young children nine were operated on by the lumbar method and two only by the abdominal. In deciding which of the two methods to adopt I have been guided chiefly by the size of the tumour and in some measure by its mobility. Hitherto there has been, rightly or wrongly, a general consensus of opinion in favour of the lumbar route whenever applicable, and it is applicable in all or nearly all in which the tumour can be brought whole through the lumbar incision. In the two removed by the transperitoneal operation the mass was of relatively enormous size, and in both there was a degree of mobility sufficient to suggest an elongated and narrow pedicle. Of the 11, one, a pallid and wasted child, 13 months old, died before the completion of the operation, and another lived only seven hours, death being sudden and probably due to cardiac thrombus arising from an injury to the vena cava. Nine recovered from the operation, but the longest survivor lived only two years and five months, whilst one was reported to have died at the end of nine weeks. In how many deaths resulted from recurrence of the disease I have no means of knowing. Three times only had I the opportunity of seeing the child when nearing the end, and in each of these were undoubted evidences of recurrence. In two others the medical men in charge reported the presence of abdominal tumour.

My results are neither better nor worse than those reported

by other surgeons. It is several years since I last undertook a nephrectomy in a young child, and unless future experience gives better ultimate results than I have hitherto met with the want of confidence I already feel in recommending the operation in children suffering from malignant growths cannot but be emphasised.

In dealing with a mortal disease an immediate mortality of a little over 18 per cent. seems encouraging enough, but when it is borne in mind that the longest survivor of 11 died within two and a half years the question forces itself upon our consideration whether it is worth while to incur the undoubted immediate risk of the operation and the anxiety to parents and friends for the possibility of so small a gain. Bear in mind it is of young children I am speaking, in whom an addition of a few months or of even a year or two of life is not comparable with a similar addition to the lives of adults. It is even doubtful if in these 11 children there was any actual increase in the aggregate length of life obtained. This raises a grave question, one which cannot, of course, be determined upon the experiences of a few. It is, indeed, too early yet to express an authoritative opinion upon the point seeing that it is only within very recent years that nephrectomy has been undertaken by the general surgeon, and the collected data, although considerable, are insufficient for the purpose. In not one of my cases was an early diagnosis arrived at and in all the disease had consequently made considerable advance before the operations were undertaken. The absence of prominent symptoms has doubtless militated against early removal in some, whilst in none probably has the surgeon deemed it right to open loin or abdomen until such time as he has been satisfied of the presence of a substantial growth. Considering with what little risk an intra-peritoneal inspection of the kidneys may be undertaken if on the earliest suspicion of a growth an examination by inspection and palpation of the organs be made it may be possible to detect the presence of sarcoma or other growth at a much earlier date than has hitherto been accomplished and so, it may be assumed, to lessen the probabilities of return. Bearing in mind, however, that the only prominent signs of the disease in young children are the presence of a tumour in one or other loin and the occurrence of hæmaturia, that whilst the latter is by no means constant the former, even though it be of foetal origin, has usually attained a considerable degree of development before its existence is suspected, the probability of very early diagnosis seems somewhat remote; and yet by early detection and prompt removal alone can we hope to improve upon our hitherto unsatisfactory results. In estimating the value of this operation it is not sufficient for the statistician to tabulate his cases under the two heads "cured" and "died"; we must be informed as to the duration of life in those reported "cured," or indeed statistics will only mislead.

Much more encouraging are the results obtained after nephrectomy in adults, partly because in the majority of cases the operation is performed for conditions other than those of malignancy, and in part it may be because of the lesser degree of malignancy usually met with in the renal tumours of the adult and of their consequent diminished liability to diffusion and speedy return. I have operated on 16 adults, of whom six had tumour, three calculous pyelitis, four tuberculous or other form of non-calculous pyelitis, two fistula following nephro-lithotomy, and one uncontrollable hæmorrhage after nephro-lithotomy. Of the six cases of tumour two recovered, two died within a few hours from shock, one died on the third day after operation with symptoms of intestinal obstruction which were not relieved by enterostomy, and one lingered nine days, gradually sinking from exhaustion. The first of the two patients who recovered after nephrectomy for tumour was a man, aged 56 years, whose chief symptoms were frequent hæmaturia, a dull aching in the left loin which was completely filled by a large growth, and increasing pallor with loss of strength. The substance was removed by the lumbar operation and it was found to consist of an upper third of normal renal tissue and a lower two-thirds of new growth which was reported to be malignant adenoma. The second case was that of a woman, aged 36 years, in whom a diagnosis was arrived at only during the progress of the operation. She was very stout and her abdomen especially was fat and large. After her third confinement nine months before she came under observation she discovered a globular substance in her left abdomen, which, however, gave rise to no inconvenience. It increased in size and in June, 1900, it was

described as being round and of the size of an average cocoa-nut. It lay in the left iliac fossa, was firm, and it had a free range of movement. It could be made to lie on the lumbar vertebrae, could be pushed upwards into the loin, leaving the iliac fossa empty, and it could be brought downwards just within touch of the fingers in the vagina at the brim of the pelvis. No attachment to the uterus could be made out. The functions were in no way interfered with and the patient's general health was good. On opening the abdomen in the middle line and exposing the tumour it was seen to spring from the left kidney. Pushing the intestine to the right it occupied the whole of the space between the twelfth rib and the iliac fossa, and was composed of the upper half of the normal kidney resting upon a capsulated growth which included the pelvis and the rest of the kidney. The upper portion of the kidney not directly involved in the growth had a remarkably elongated appearance, as if it had been stretched by the weight of the tumour, and by its means the range of movement was greatly increased. Its peritoneal covering having been incised and stripped off the pedicle was secured and the whole removed. Drainage was effected through the loin and the peritoneal wound was closed by suture. The tumour was composed of a mass of cysts inclosed in a thick capsule and contained no malignant element.

The four patients who died presented large tumours and in all the transperitoneal method was the operation selected. Two males, aged respectively 53 and 61 years, and one female, aged 34 years, were the subjects of disease in the left kidney pronounced to be sarcoma. The fourth was a male, aged 56 years, with carcinoma of the right kidney and adrenal extensively adherent to the under surface of the liver. Of the 10 adults in whom nephrectomy was performed for conditions other than that of tumour two died and eight recovered. One of the fatal cases was that of a young man from the substance of whose kidney I had removed a calculus by an incision made directly over the stone through the substance of the kidney tissues. Very free bleeding at the time of operation was temporarily arrested by pressure and it was not until after several recurrences of the hæmorrhage during the next three days that it was decided to remove the kidney. At the operation the wound was believed to be in a septic condition, infected probably by the suppurating pelvis of the kidney. In spite of much care and pains taken to cleanse the wound the patient died from septic peritonitis. The other fatal case was that of a delicate woman, aged 30 years, from whom I had a few months before removed four small calculi found loose in the pelvis of the kidney, which was also largely distended with pus. It had become evident that the patient must sink. The lumbar nephrotomy wound continued to discharge pus mixed with some urine in large and undiminishing quantity, the condition of the patient was deteriorating, and the temperature pointed to a general septicæmia. In the hope of being able to arrest this down-grade the kidney was removed through the loin. The patient only survived the operation 58 hours, and during that time no more than eight ounces of urine were secreted. Of the eight who recovered three were the subjects of calculous pyelitis and had previously undergone the operation of nephro-lithotomy; four were for tuberculous or other form of non-calculous pyelitis, and, like the former, had previously undergone nephrotomy; and one was for urinary fistula following nephro-lithotomy. In each the lumbar operation was selected.

It will thus be seen that of the five transperitoneal operations four died, whilst of the 11 lumbar nephrectomies two died, showing a difference as between 80 and 18 per cent.; whilst if the whole 16 be classed together, with six deaths, the mortality is 37½ per cent. This places the transperitoneal operation in a very unfavourable light. But in estimating the relative dangers of the two operations the nature and extent of the disease, as well as the character of the operation itself, must be taken into account. The lumbar route being inapplicable to the largest tumours—and the larger the tumour, other things being equal, the more dangerous its removal—it follows that some of the least promising are transferred to, and made to swell the mortality of the abdominal operation. So, again, the age of the patient must influence the death-rate. Of the four who died one was over 60 and two between 50 and 60 years of age. A mortality of 37½ per cent. cannot be accepted as at all satisfactory, and increased experience leading, as doubtless it will, to improvements in the technique of the operation and the avoidance of many pitfalls may be

confidently reckoned upon for the securing of better results. How far, for instance, with improved methods of combating or averting shock we may be able to lessen the mortality the future will decide. At the time when the four transperitoneal operations for tumour were undertaken we were not in the habit of injecting strychnine hypodermically or of introducing saline solutions within the veins, two powerful agents without which no surgeon would at the present day consider himself sufficiently armed when undertaking operations of such magnitude or involving such prolonged anaesthesia. The two patients at least who died within a few hours of the operation I cannot but think would have had a better chance of recovery had we been able to make use of the means for averting shock with which we are now familiar.

In weighing the advantages and disadvantages of the two operations with a view to selection in a given case it must be noted that in the anterior method the peritoneum is twice incised, whilst in the posterior that membrane is not necessarily wounded at all. This is a matter of very considerable importance, more especially if the organ to be removed is in a septic condition, as is the case in all suppurative diseases. Speaking generally, the lumbar route is to be selected in preference to the anterior whenever the kidney is known to be undergoing septic inflammation, as also in those cases of neoplasm which present no such difficulties as are due to mobility or to extreme size; for whilst the danger of soiling the peritoneum during the extraction of a septic organ through an anterior opening is a very real one, and would lead to a preference for the posterior route, the difficulty of removing a very large growth through the limited space between the costal margin and the iliac crest or of enucleating a kidney having a free range of movement within the abdomen would suggest the desirability of attacking it from the front. The transperitoneal method possesses further advantages, such as enabling the operator to examine the opposite kidney as well as the other abdominal organs, in any of which might be found secondary growths or other conditions sufficient to negative the completion of the operation; and again the readiness with which the renal vessels may be secured in such manner as to render the operation a comparatively bloodless one.

On reviewing my own work apart altogether from results, for indeed the number of cases is not sufficiently large for statistical purposes, I incline to the opinion that the lumbar operation will continue to be preferred for those cases in which sepsis is known or is assumed to exist and for those neoplasms in which the growth is of recent origin and of small or moderate size; whilst the larger renal tumours will be attacked from the front with more prospect of success in proportion to our increased knowledge of, and attention to, details in the operation itself and to our ability to avert death from shock. I have said that nephrectomy in the adult gives more encouraging results than is obtained in children. This declaration must be qualified in that it applies not to the immediate but only to the ultimate result. It will have been seen that of the 11 children nine recovered from the immediate effects of the operation, showing a mortality of 18 per cent., whilst of the 16 adults six died whilst under treatment, giving a mortality of 37½ per cent.; but on inquiring into the future history of these 10 adults whose operations were successfully accomplished we find a much more favourable record than in the cases of the children, the longest survivor of whom you will remember died within two and a half years. Of the 10 adults who recovered one, aged 55 years, the subject of "malignant adenoma," attended with persistent and profuse hæmorrhage, whose kidney was removed by the lumbar method in 1888, survived nine years without any sign of return of the disease, the cause of death being certified "cardiac dropsy." This man during several years after the operation continued to work as a compositor in a newspaper office, and on several occasions he assured me that his health was in no way impaired. Another of the successful series was that of the woman, aged 36 years, whose left kidney with tumour attached was removed by the anterior operation in June, 1900. The growth in her case was reported on as one of cystic degeneration devoid of malignant elements, and she is now in good health. Of the remaining eight successful nephrectomies—all of which, undertaken for conditions other than that of neoplasm, were performed by the lumbar method—three are known to be still alive and well, and their respective operations bear the dates 1883, 1890, and 1891. One was reported to be in good health 15 months after the

operation, one migrated to Australia "about three years after his kidney was removed," and of three I have failed to find any trace. Such results as these, if we take into consideration the hopeless condition in which most of the patients were placed at the time their operations were undertaken, imperfect though they are, cannot fail to encourage us in persevering with a radical treatment which, if essentially fraught with risk, may yet admit of such improvements as will lead to greater and more certain success in the future.

In furtherance of my intention to place before you some examples taken from my own personal experience in renal surgery, and altogether repudiating any pretensions to originality or claim to address you *ex cathedra*. I will now pass on to a brief consideration of nephro-lithotomy—an operation which I confess not to have held in the highest estimation until within the last five or six years, owing, as I now realise, to the non-recognition of essential anatomical considerations. In October, 1882, I attempted to sound a kidney for stone by means of a long fine needle passed through the loin, and whilst the instrument was being manipulated it snapped, leaving five inches buried in the tissues. This *contretemps* compelled me to incise the loin, and owing to the difficulty I experienced in finding the needle, which, however, was eventually recovered, the kidney was exposed and I was thus enabled to make a more thorough exploration by means of the needle passed in many directions and to varying depths. The result was negative as regards the discovery of a calculus, but from that time the renal pain disappeared, and thus a cure, which at that date and for many years after seemed inexplicable, was accidentally brought about. Not until 1886 did I succeed in locating and removing a calculus, although I had in the meantime made unsuccessful attempts on four patients to discover a suspected calculus by means of manipulation and needle puncture of the kidney exposed at the bottom of a lumbar incision. Fortunately, no harm was done to any of the four. The patient from the pelvis of whose kidney I succeeded for the first time in removing a calculus had a narrow escape from death by hæmorrhage, owing, doubtless, to the position and direction of the incision which was made on the anterior aspect of the kidney immediately beyond the pelvis parallel with the long axis. The stone was branched, it weighed a little over two drachms, and was so embedded in the kidney structure as to cause some amount of tearing in its extraction. Hæmorrhage, very free at the time from the wound, was eventually arrested by sponge pressure, and as on removal of the sponge a few hours later the hæmorrhage had apparently ceased, whilst there was no indication of an escape of urine, the external wound was closed. Next day, as he had not voided urine and the bladder was found to be moderately distended, a catheter was passed and some deeply-stained urine drawn off without materially lessening the distension. Upon this a suction syringe was improvised, and by its means a large amount of coagulated blood was extracted. As upon examination the lumbar wound was found to be in a wholly satisfactory state further interference seemed uncalled for. During several days the pumping operation had to be repeated, but eventually the bleeding ceased and his recovery progressed slowly to its completion. In 1888 there occurred the unfortunate case I have previously mentioned, in which, after an incision similar to the one just described, repeated external hæmorrhage extending over several days decided me to remove the kidney with the result that the patient died from septic infection. It thus became manifest that hæmorrhage constituted a formidable danger in the removal of calculi impacted in the kidney substance.

Amongst my early cases, again, were two in which stones were readily discovered by palpating the pelvis, and were almost as readily removed through direct incisions in the pelvic wall without implicating the kidney tissue proper. In one of the two I made an attempt to suture the wound, but in both the whole of the urine continued to flow through the drainage-tube and permanent fistulae became established. Relief from the intolerable nuisance produced by the leakage was at length obtained by removal of the organ. For a time my hope for the future of nephro-lithotomy fell to a low ebb, and I almost despaired of seeing it established as a useful operation. Interest, however, was revived in May, 1888, by a successful issue in the following case. A farmer, aged 52 years, came under my care in the infirmary complaining of loss of strength and of his urine being "milky." He was

stout and sallow-faced, of aged appearance, and flabby-limbed. His complaints were exceeding few. His urine contained one-fourth pus, and the left half of his abdomen was occupied by a smooth definitely outlined elastic tumour. He had never known pain, had worked up to the time of his admission, and had only noticed the change in his urine for a few weeks. He was not an observant man, and his previous history was almost a complete blank. On a diagnosis of pyonephrosis I cut down upon the left kidney, and on incising it 26 ounces of pus were collected. A digital exploration of the thin-walled sac into which the kidney had been converted revealed the presence of an unusually large stone, which after extraction by means of large lithotomy forceps was found to weigh 11 ounces 160 grains (Fig. 2). It was firmly adherent and had to be peeled off, so

FIG. 2.

Renal calculus (rather more than half-size) weighing 11 ounces 160 grains.

intimate was its connexion with the pelvic wall. The kidney was a mere shell and had ceased to perform its function, for at no time was there any discharge of urine from the drained wound. During the first few weeks pus flowed freely though in diminishing quantity, and in little more than four months the wound was closed. About five years after the operation, having meanwhile enjoyed good health, he died with symptoms, so I was informed, of intestinal obstruction. In view of the enormous size of the stone and of the very extensive character of the disease in this case the entire absence of pain from commencement to end forms a very remarkable feature which serves, however, to emphasise the fact, verified again and again in my own practice, that the amount of suffering in nephro-lithiasis bears for the most part an inverse relation to the size of the stone. A small mobile calculus lying loose in the pelvis, partially blocking now and again the orifice of the ureter, gives rise to greater and more frequent pain than does a larger one fixed in a calyx or imbedded in the kidney substance. This, by far the largest specimen I have myself removed, was unattended with pain at any period of its formation or growth, whereas the patient who within my recollection suffered most, and most frequently, requiring daily administration of morphia for a period of from three to four months, eventually passed a small lithic acid calculus per urethram to her complete and permanent relief. It is worth mentioning in this connexion that the stone was passed during the night following my first examination of the patient, which included a free manipulation of the loin, and resulted in arrangements being made for a nephro-lithotomy on the following morning—arrangements which were, of course, indefinitely postponed. How far it may be claimed

that the stone received a determining impulse on its outward passage from the hands of the manipulator I am unable to assert, but that such an explanation is not wholly chimerical receives some support from the following two cases.

I was asked by the directors of a railway company to examine on their behalf a man who was seeking compensation for damages received in a collision. The injuries were severe and indicated considerable violence. Amongst the details of the accident it was stated that he was thrown upon the floor of the compartment where he received several blows upon his back from other passengers falling in a confused heap upon him. After having been conveyed home his sufferings were so severe that, pending the arrival of a medical man, his wife had him placed in a hot bath. Whilst lying there micturition became imperative and frequent, the urine being decidedly blood-stained, and at length he emitted a lithic calculus of the size and shape of a barleycorn. The other case was that of a young man suffering from well-marked renal colic, in whose kidney I failed to detect a stone by careful manipulation and needle puncture. The search was abandoned and the wound was closed. Early next day he was found to be suffering from retention of urine, due to the impaction of a calculus in the membranous urethra, plainly felt in the perineum. It was removed through a median incision and the retention was speedily relieved. In the one case the escape of the calculus so shortly after the patient had been violently shaken and severely pounded, amply suggests cause and effect, whilst in the other case there is little room for doubt that the search by palpation of the kidney and its pelvis directly resulted in the escape of the stone and its forced entrance into the ureter. The possibility, therefore, of a stone becoming detached and released should not be lost sight of lest an additional danger be introduced necessitating a further operation for the recovery of the stone, the presence of which in the ureter or elsewhere has become a matter of certainty.

To return, after this diversion, to the early misgivings I entertained in regard to the future of the operation of nephro-lithotomy, misgivings which were in no degree lessened by the satisfactory result following the removal of this exceptionally large stone. Up to the year 1896 I had operated on 19 patients whose symptoms had led me to diagnose stone in the kidney, exclusive of two in whom unsuspected stones were met with, that, viz., in whose attenuated kidney the large calculus was found, and another who presented similar symptoms of pyonephrosis only and in the pelvis of whose kidney, besides a quantity of pus, two calculi were discovered. In none of the 19 operations was the kidney withdrawn from its normal situation; it had not, indeed, occurred to me that such a procedure was feasible. The plan adopted had hitherto been to expose the kidney by incision through the loin, to strip it anteriorly and posteriorly of its investing fat, to palpate the whole organ, including its pelvis and the upper portion of the ureter, to needle-puncture in every direction those cases in which simple palpation gave negative results, and, finally, to cut directly upon the stone wherever one was discovered, whether in the substance of the kidney, in the pelvis, or in the upper reaches of the ureter. In five cases no stone was then or thereafter found; in one a displaced stone was subsequently extracted through an incision made in the perineal urethra; in two severe hæmorrhage—leading to a fatal nephrectomy in one—followed the incision made directly over the stone through the kidney substance; in two nephrectomy was resorted to for relief from permanent urinary fistula; and in nine recovery was uncomplicated and complete.

About the year 1896, in a conversation with him respecting a patient suffering from advanced tuberculous disease of both kidneys, Mr. Henry Morris stated that he was in the habit of withdrawing the kidney from its bed so as fully to expose it outside the lumbar wound, of splitting the organ into two symmetrical halves by an incision carried from its convex border through to the pelvis with the object of curetting and otherwise treating masses of tubercle, and of returning the kidney to its natural position after having passed three or four catgut sutures deeply through the substance of the organ which he tied with just the amount of force needed to arrest the bleeding. Since that time I have adopted a similar procedure in the removal of stones from the kidney in five cases with most satisfactory results. In none has there been any difficulty in controlling the hæmorrhage; in

all the wounds healed directly and there has been no urinary fistula to complicate the results. Should the future confirm these experiences nephro-lithotomy will have been deprived of two of its chief dangers—those, viz., of severe hæmorrhage at the time of operation and afterwards and of that most troublesome and distressing condition, a leakage of urine through the loin, in addition to which there are the manifest advantages during the operation of a complete inspection of the kidney and its pelvis and the consequent diminished likelihood of overlooking a stone, together with a greatly increased facility of examining the ureter from end to end by means of a probe in case of suspicion that a stone has escaped during the earlier steps of the operation.

To account for the abundant hæmorrhage attendant on an incision through the anterior or the posterior surfaces of the kidney as compared with one made through its centre, splitting it into two symmetrical halves, it is needful only to bear in mind the arrangement and mode of distribution of the renal vessels when once they have entered the organ and the very liberal supply of blood which they receive. The radiating interpyramidal arteries and veins intercommunicating by arches across the pyramidal bases, from which numerous vessels carry the blood to and from the cortex, constitute a plexus which if anywhere cut across pours out blood as freely almost as if the renal vessels themselves were wounded. The further we proceed, on the other hand, from the primary branches of the renal artery into the substance and towards the periphery of the cortex, the smaller the vessels become and the more easily is the bleeding controlled, and thus it follows that an incision carried from the outer border of the kidney straight through its centre to the pelvis, involving fewer of the primary branches, is attended with less hæmorrhage, and that of a kind more easily arrested, than if the incision is made transversely across the organ. So also as regards the formation of urinary fistulæ, incisions made through the comparatively thin walls of the ureter or pelvis, more especially if these be diseased owing to the presence of a stone, are less likely to result in primary union than are the extensive, even, and vascular surfaces of the two halves of the kidney when accurately approximated by deeply placed sutures. It has not, moreover, in every case been necessary to split the entire kidney, but I have not hesitated to do this where such a course has been called for, and in all the incision has been commenced at the convex border and carried down to the pelvis, or so far as has been needed to expose the stone.

In withdrawing the kidney so as to inspect it outside the loin the danger of tearing the pelvis or even of detaching the ureter must not be lost sight of. The former accident actually occurred in my hands, and although by carefully suturing the wound a fistula was avoided, the risk of establishing a permanent leakage is greater when the pelvis is torn than in the case of an incision made for the purpose of extraction, and we have seen that in two cases—in neither of which, it is true, was any attempt made to suture the edges of the incision—this untoward result was brought about. The pelvis which has been long occupied by a stone and has thereby become attenuated, and more especially if the seat of a pyonephrosis, will be likely to give way more readily to the stretching than one in a state of health, and the wound in it will, moreover, be less likely to close no matter how carefully sutured. Bearing these possibilities in mind, the withdrawal and exposure of the kidney followed by the operation of splitting, muffin-like, is calculated, I feel sure, not only to facilitate the removal of stones from the interior of the kidney, but to render the operation safer and more effective.

In no single branch of surgery have more important changes and improvements been made during recent years than in the method of dealing with stone in the bladder. Within the recollection of every middle-aged surgeon a complete revolution, indeed, has been witnessed, and it may be considered not altogether inappropriate if, after having indicated the method of dealing with calculus in the kidney which in my hands has given the best results, I conclude by making a few observations upon the present and former procedures made use of for the removal of stones from the bladder. Only a little while ago the choice lay between perineal lithotomy and lithotripsy as practised by Civiale. It is doubtful if at the present day half-a-dozen hospital surgeons could be found in this country who are in the habit of performing either operation. During several generations lateral lithotomy stood at the head of the list of the surgeon's performances, and few of the elders amongst us can fail

to feel a pang of regret on looking back to the days when students and other onlookers anxiously watched whilst the surgeon with more or less precision and rapidly relieved his patient of the stone. Lateral lithotomy was the accepted test of the surgeon's claim to pre-eminence as an operator, and few, I imagine, ever experienced an entire absence of nervousness when about to undertake its performance. The oldest, most experienced, and most successful lithotomist of my acquaintance published a confession that he invariably suffered from a feeling of nervousness when about to undertake the removal of a stone, and as on no other occasion was he the subject of fears or qualms he termed it his "lithotomy feeling." There was good excuse for this. So many pitfalls surround the operation as to make it a matter of relief when it is safely completed; so many excellent operators have failed once at least in bringing about a successful issue. The traditions of almost every large hospital contain at least one example of failure. I have myself seen one of the ablest surgeons of his day remove a stone of considerable size by this operation from an adult in whom, post mortem, it was found that neither urethra, nor prostate, nor rectum had been wounded, a result which elicited from an enthusiastic admirer the remark that the operator was probably the only surgeon in England who was capable of performing such a feat. Notwithstanding the difficulties and dangers attendant upon the operation itself, the occasional occurrence of unpleasant sequelæ, and the mortality, amounting in the best hands to one in eight, and in spite of the many attempts at modification—bilateral incision, median incision, the use of a curved, of a straight, or of a rectangular staff—lateral lithotomy maintained its position at the head of cutting operations for stone until within 20 years of the present time.

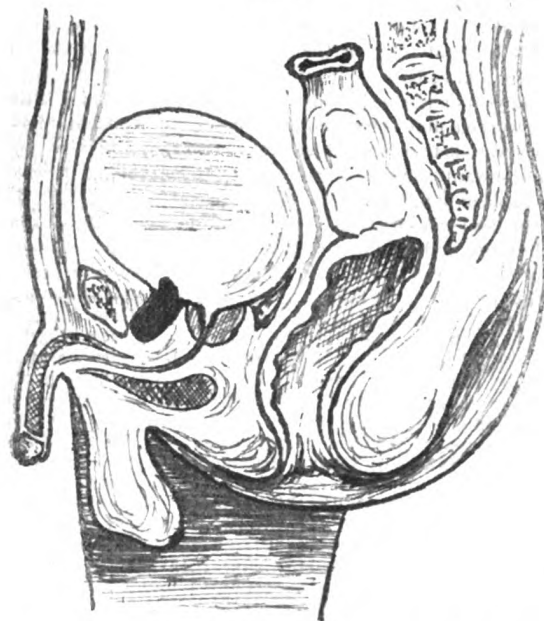

Lithotripsy, in the hands of a few skilful manipulators, from the time of its introduction, about the middle of the first half of last century, gradually increased in favour as the instruments for crushing and evacuation were improved, but it cannot be said at any time to have rivalled the cutting operation, being for the most part reserved for those comparatively few favourable cases in which the stone was small and the organs were generally healthy. It was not until the gradual development of lithotripsy into the more complete litholapaxy at the hands of Bigelow, nearly a quarter of a century ago, and the almost simultaneous revival of suprapubic lithotomy, that the doom of lithotripsy and of lateral lithotomy was sealed.

The manifest advantages and the vastly increased safety secured by removing at a single sitting the crushed fragments of a stone, whether small or of a considerable size, the precision and certainty with which the bladder was opened, digitally explored and even inspected through an anterior incision, were not long in obtaining for the two new operations an established position, and at the present time I shall not be far wrong in saying that with very few exceptions litholapaxy or suprapubic lithotomy is chosen in every case of vesical calculus whether in male or female, in child or adult; and litholapaxy claims first consideration. There must be some good reason for deciding upon lithotomy in preference to litholapaxy now that the latter operation in skilled hands and in well-selected cases is attended with so little danger and incurs so brief a period of disability. The mortality, no doubt, after either method of extracting a stone depends less upon the nature of the operation itself than upon the presence or absence of complications. Apart from the general health and strength and age of the patient, the size and composition of the stone, the capacity of the urethra, the presence or absence of prostatic enlargement and of inflammatory disease in bladder or kidneys, must materially influence the results. In a perfectly uncomplicated case, one in which a successful issue may be expected from either operation, litholapaxy would naturally be chosen as involving less mutilation and a less prolonged period of convalescence. Some complications there are which, apart from other considerations, entirely negative the less serious procedure; such, for instance, is the presence of an advanced stricture in any part of the urethra beyond the meatus, with which I may class an abnormally narrow urethra, one which admits only an instrument altogether disproportionate to the size of the stone. I have met with one instance in a generally ill-developed man of middle age whose urethra, though showing no signs of disease past or present, would not, even after the slitting of the meatus, admit the smallest sized lithotrite I possessed. The presence of advanced prostatic disease may be, I think,

rightly held to exclude litholapaxy, not so much on account of the obstruction it presents to the free use of the lithotrite and evacuator, or on account of its liability to injury, but chiefly because by adopting the suprapubic operation an opportunity is afforded for dealing radically with the prostate as well as for removing the stone.

There are calculi too large to be crushed, and a few—I have met with two such—so hard as to resist the most strenuous efforts to break them. The presence of cystitis, if of long standing, must be held, certainly if the stone be of more than moderate size, to contra-indicate the crushing of the stone, seeing that a prolonged operation involving more or less injury to the bladder would incur the risk of converting a mild into an acute and relatively dangerous state of inflammation; and finally, in the case of an encysted calculus, litholapaxy may be considered to be wholly inapplicable, not only because of the difficulty, for the most part insuperable, of releasing the stone from its pouch and of effectually breaking it into fragments which shall be accessible to the aspirator, but also because of the intense cystitis which, so far as my observation extends, is a marked feature in cases of encysted calculus. In these the superiority of suprapubic lithotomy over any other form of operation is abundantly manifest, and seeing that I have met with three such cases, whilst the total number successfully operated on is very small, I desire here to place them on record. The first was that of a young man of very poor physique in whom the sound struck a stone the moment it entered the bladder. His symptoms had been of long duration and markedly pronounced, so that I concluded that the stone was large. A lithotrite passed into the bladder grazed the under surface of the stone, but all attempts to seize it proved futile. With the left forefinger in the rectum and my right hand placed on the lower abdomen I could distinctly feel the projecting calculus fixed beneath the pubic arch. Here was a combination of circumstances which might be said to invite an attack from above, and accordingly I proceeded at once to perform my first suprapubic lithotomy. Sir Henry Thompson had but a

FIG. 3.

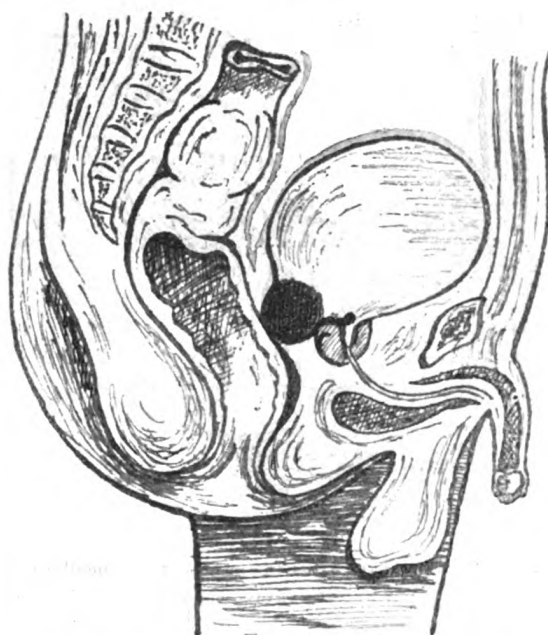

Sagittal section to the left of the middle line through the pelvis, showing an encysted calculus in the bladder beneath the pubic arch and to the left side, removed by suprapubic lithotomy from a young man. (Weight, seven drachms.)

few months before described the operation in detail, and I followed in the main the directions which he had given. On inserting my finger through the suprapubic opening it immediately impinged upon a stone slightly projecting on the left of the urethra. A further examination revealed the fact that the calculus was imbedded to about three-fourths of its extent in a sacculus occupying a space below the pubic arch and between it and the prostatic urethra. (Fig. 3.) From

this hollow it was shelled out by means of a scoop and the finger and then readily removed. I do not believe that by any other operation the stone could have been extracted. No finger could have done more than touch the exposed end if introduced through the perineum, nor could any lithotrite have been made to grasp the stone between its blades. Of further complications there were none, and the patient's recovery was uninterrupted. The second case, which came under observation at the infirmary in 1888, was in a man 73 years of age. His urethra, owing to what was supposed to be an enormously enlarged prostate, did not readily admit a sound, and on that account, as also because of his advanced age, the severity of his symptoms, the presence of a considerable amount of muco-pus in the urine, and the fact that his bladder retained from six to eight ounces of residual urine, the suprapubic operation was decided upon. A globular oxalate calculus weighing 13 drachms was removed from a pouch at the base of the bladder situated on the right of the middle line, which concealed all but the slightly projecting surface of the stone. (Fig. 4.)

FIG. 4.

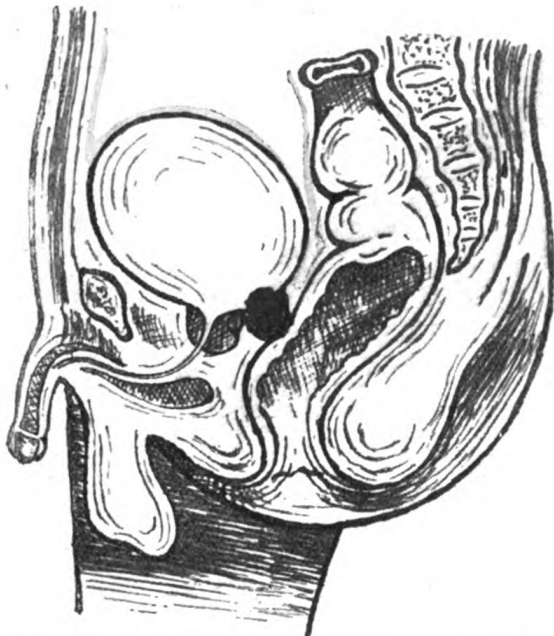

Sagittal section to the right of the middle line through the pelvis, showing an encysted calculus on the right of the base of the bladder and a projecting middle lobe of the prostate in a man, aged 73 years, both removed by suprapubic lithotomy. (Weight of calculus, 13 drachms.)

This it was which had led to the supposition of his prostate being largely hypertrophied. As a matter of fact the prostate was enlarged, but the hypertrophy was confined to the middle lobe, which, projecting upwards in such a manner as to obstruct the urethral entrance, was removed. Recovery followed. The third case came under my care in 1899. The patient, aged 60 years, after having long suffered from painful micturition had the misfortune whilst following his occupation to crush his perineum by falling from a height astride a beam. Urethral laceration, attended by copious hæmorrhage, was followed by a troublesome stricture which added considerably to his urinary difficulties and suffering. Prior to the accident he had undergone treatment for cystitis. When brought under my observation some months after his accident his condition was most unpromising. His urine, passed guttatim, was purulent and offensive. He was sallow, thin, and devoid of appetite. As a No. 3 gum elastic catheter had been occasionally passed with temporary relief and without exciting any febrile disturbance I began gently to dilate the stricture by means of Lister's sounds, beginning with 2-5. Before I had proceeded far the sound struck a stone, and thus I found myself in face of an added difficulty. My first impulse was to perform external urethrotomy and to extract the stone through the median incision, but as for this I was not

prepared proceedings in that direction were arrested. Further dilatation enabled me to make a closer and more detailed examination. First I satisfied myself of the facility with which a free dilatation of the urethra could be accomplished; then I was able to make out by means of the sound that the stone was of considerable size, that it lay on the left at the base of the bladder, that it was fixed in its position, and lastly, by means of the finger in the rectum, that it projected backwards beyond the prostate towards the sacrum and was probably situated in a pouch. On a subsequent day I opened the bladder above the pubes and removed a calculus weighing 10 drachms from a pouch situated as I have just described, which inclosed almost the entire stone, leaving only a segment of its surface exposed. His future course and recovery were uneventful. (Fig. 5.)

FIG. 5.

Sagittal section to the left of the middle line through the pelvis, showing an encysted calculus on the left of the base of the bladder, removed by suprapubic lithotomy from a man, aged 60 years. (Weight of calculus, 10 drachms.)

The success attendant upon these cases thus briefly narrated, together with the facility with which the stones, though deeply imbedded in the bladder wall, were extracted, weigh much with me in estimating the relative value of the several modes of performing lithotomy. In the first case, as I have already remarked, by no other route could the stone have been removed; in the other two the difficulties of their extraction through the perineum must have been well-nigh insurmountable, whilst in none of the three would it have been possible to grasp the stone within the blades of a lithotrite.

Up to the year 1883 perineal lithotomy, lithotripsy, or a combination of the two in the case of a very large stone, was adopted in my practice in every case, lithotripsy being reserved for the smallest stones in adults whose general conditions were favourable, median perineal lithotomy selected for small stones in children, and lateral or very rarely bilateral lithotomy for medium-sized and large stones at all ages. From 1883 to 1890 was a period of transition. Litholapaxy was rapidly superseding lithotripsy, and the suprapubic lithotomy was with almost general consent replacing the perineal operation. Since 1890 my practice has been without exception limited to the two operations, litholapaxy and suprapubic lithotomy—to the former whenever I have found it reasonably practicable, irrespectively of the age of the patient and to a great extent of the size of the stone; to the latter whenever existing conditions were such as definitely to forbid the use of the lithotrite and aspirator, and in a few instances in which the weight of evidence seemed to favour the shorter, if on the whole

severer, measure. With these two operations and their results I feel much reason to be satisfied; and although finality is no more applicable to the treatment of stone in the bladder than to other surgical problems I feel little doubt that in the near future any improvement in our means of dealing with calculous formations must be directed to the perfecting of our present methods of procedure rather than to the discovery of new operations or the revision and revival of the old. Perineal lithotomy, associated though it has been with many generations of the greatest surgeons in the world, up to a few years ago universally held to be the most important operation in surgery, is now all but relegated to the past, lingering only, I believe, in the hands of the few, and is doomed almost certainly to become ere long a subject for the historian alone.

The three subjects upon which I have so cursorily discoursed are not the least important amongst the many which have exercised, and still are exercising, the minds of the present generation of surgeons. In each there is much need for increased experience and for wider observation, and if my small contribution be considered at all worthy of the acceptance of this audience I shall feel myself more than rewarded.

## An Address

ON

### A MODEL HOSPITAL.

*Delivered at the Opening of the New Victoria Wing for Out-patients at Bolingbroke Hospital, Wandsworth Common, on Dec. 11th, 1901,*

By THOMAS BRYANT, F.R.C.S. ENG.,  
M.Ch. R.U.I.,

SURGEON-IN-ORDINARY TO THE KING; SURGEON TO BOLINGBROKE HOSPITAL; CONSULTING SURGEON TO GUY'S HOSPITAL, &c.

CANON ERSKINE CLARKE, LADIES AND GENTLEMEN,—I accepted with much pleasure the invitation of the governors of this hospital to open to-day its new out-patient department, as I have been connected with the hospital for more than 12 years and cordially appreciate the way in which it has been worked and is now conducted. I might recently have regretted that the main object its founder had in view has from the wants of the neighbourhood been obliged to take a back place, but I bow with respect to the necessities of the position and will, with my colleagues, do our best to work the hospital under its new conditions. The hospital, as most of you know, was founded in the year 1880, with the praiseworthy object of helping those who were willing and able to help themselves; for its founder, and our life-long President, our friend the Rev. Canon Erskine Clarke, fully recognised the fact that the free hospital system as generally established, though full of good influences, had a tendency to sap the self-reliant manhood and womanhood of the poorer classes, which it is so right to foster, and consequently to pauperise a large section of the well-to-do artisans and others who have the inclination and power to pay part of their cost when they are compelled to seek hospital treatment. With this well-conceived object this mansion was purchased, fitted up, and opened as a self-supporting hospital by Canon Clarke at his own risk, but with the aid of contributions, and with the hope that a sufficient number of patients would be found able to pay more than their cost, so that others might pay less, and that thus the hospital would be maintained. For 16 years the hospital was carried on upon these lines, with fluctuating and variable success, and during this period the founder had to advance large sums of money to keep it going. For the last three years of this period, also, great pressure from the outside leaders of labour was brought to bear upon the hospital authorities to change its constitution so that accidents might be admitted to its wards and out-patient casualties be attended to—for during these years Battersea had been rapidly growing and had become an important manufacturing centre, and it was naturally felt that with a hospital on Wandsworth Common it was rather hard, and in a measure detrimental to those who were the

subjects of accidents, to be denied access to the surgical treatment which was possible at their Home, Bolingbroke Hospital, and to be sent for treatment to St. George's Hospital, St. Thomas's Hospital, or Guy's Hospital, which were from four to five miles distant. Under this pressure and with a full appreciation of the urgent requirements of Battersea the governors of this hospital felt called upon to change in a measure the hospital as a self-supporting institution in to what it has since become—a free hospital for the admission of accidents and emergencies supported by voluntary contributions, relegating with regret the paying class into a less prominent position, although wisely still retaining it.

The following facts will help you to understand why the governors of the hospital were influenced and how necessary the change in the constitution of the institution had become, for in the course of the latter five months of the year 1893, when the change of practice commenced as an experiment, seven patients were as subjects of accident admitted into the hospital and 217 attendances of patients were given as out-patients. In 1894 there were 19 admissions and 980 attendances; in 1895 there were 64 admissions and 1784 attendances; and in 1896 there were 105 admissions and 3719 attendances—this year being the last of the old régime, for in December, 1896, the hospital became incorporated, and in 1897 the present home and free accident hospital for the treatment of in- and out-patients was practically started. How it has progressed since that date and how much the district appreciated the hospital the following figures well prove, for in 1897, the first year of its incorporation, there were 179 admissions and 9139 attendances; in 1898 there were 219 admissions and 13,668 attendances; in 1899 there were 217 admissions and 14,142 attendances; in 1900 there were 255 admissions and 15,162 attendances of 3206 new free patients. And in the 10 months of the year 1901 there have been 334 admissions, and far larger figures of attendances, whilst the attendances of cases of throat and ear diseases during this same period ran up from 148 in 1894 to 1108 in 1899.

This hospital is now, therefore, practically a free hospital for accidents and emergencies and its board of management looks to the inhabitants of this large industrial district with a population computed at 500,000 and their friends for the financial support which is not only essential to enable it to carry out its present functions, but to meet the rapidly growing requirements of the future. It is true that the new building which we have this day met to open will do much to facilitate the work of the out-patient department which has hitherto been carried on under grievous difficulties, but it will do no more. We want, and urgently want, more free beds for accidents as well as for the diseases which follow accidents, for at the present time we have but 30. In the excellent scheme which has been designed for future buildings, and which is displayed to-day for your inspection, these wants will be met. It has been drawn up by the medical staff under the supervision of Mr. Keith Young and is in every particular up to date. The scheme only wants your pecuniary support to enable it to be carried out, and I most strenuously urge your early attention to this great requirement. To defray the cost of this new out-patient department about £6000 have been wanted. A large proportion of this sum has been collected, including two liberal donations from the Prince of Wales's Fund; but a balance of at least £600 is needed to allow the governors to start clear of debt. Much more money will necessarily be required to complete the building as proposed, but it can be carried out piecemeal; and from the drawings you will learn that it can be done in three blocks. Each block may have its own name. The one which we have to declare open to-day will be the "Victoria Wing"—what better name could be found, for in the word "Victoria" all human goodness seems to be embodied as in the personal qualities of our late lamented sovereign. May other names implying as much be speedily attached to the blocks to be added, and may the blocks be reared higher. Let us hope that there will be some competition to secure the honour of having names attached to the blocks; there are only three that can be so associated. I wish that I could be one of the competitors for fame, for nothing would give me greater pleasure than having my name associated as its founder with such a block, but I am not a wealthy manufacturer and have more to do with mending broken things and helping lame dogs over stiles than making anything; but I envy those who have the means, and they are many, and I at any rate have

a pleasure in pointing out to those who have the power and will to do good the means of immortalising their names by such a work.

And here I must draw your attention to a special feature in the working of this hospital which in the past has been the secret of its success and in the future is not likely to be of less value—and that is the invaluable coöperation of the medical practitioners of the district in carrying on the hospital work. Indeed, I look upon this institution as an object lesson which has proved how by a little tact and useful methods a hospital can be made popular to the medical as well as to the lay classes without any loss of usefulness and with mutual advantages. In 1893, when the pressure from without the hospital was brought to bear upon the governors to admit and to treat accidents, the question was referred by the governors to the local medical practitioners, and at a meeting of these gentlemen with the resident medical officer, Mr. C. R. C. Lyster, whose tact and influence are of a high order, the following rules were drawn up:—

1. Emergency cases to be attended at once.
2. If possible patients after being attended are to be sent home to be under the charge of their own medical man.
3. If unable to leave the hospital the patient's own doctor will be so informed, in order that he may take charge of the case if found expedient.
4. The doctor of all in-patients to be consulted as to their means of paying either the whole or part of their cost while in the hospital.
5. Cases not sufficiently serious to be admitted as in-patients, and yet requiring dressing and attendance which they are unable to pay for, will be treated at the hospital free on the written request of their own doctor.

These rules were subsequently accepted by the board and passed and adopted as the rules for attending accidents. Indeed, all accident cases have been attended under these rules for the three years antecedent to the date of the incorporation of the hospital in 1896, and, in fact, have been so ever since they were originally made.

The leading principle upon which this hospital was originally founded and upon which it has been incorporated as an association is as follows: to provide accommodation for the reception of in-patients and treatment of out-patients suffering from disease, accident, or injury who are *unable to pay*, as well as those who are *willing to pay* wholly or in part, but that no patient shall be admitted (unless from accident or emergency) except on the recommendation of a duly qualified medical practitioner. The governors of the hospital entirely approve of this principle and strongly support it. In their report for 1900 they say: "The system of referring the out-patient cases to a medical practitioner in the neighbourhood in which they are resident in order to ascertain if the case is suitable for hospital treatment continues to work effectively and without friction, and the governors are satisfied that it prevents the abuse of the hospital by those whose circumstances permit of their paying a medical man"; and this opinion I cheerfully endorse.

The principles upon which the hospital has been incorporated are somewhat novel, and to the governors of our large general hospitals they may seem difficult to act upon or unsound; but if such thoughts exist in the minds of any of those who have honoured us by their presence on this occasion I can assure them that they are wrong, for it is not possible for any hospital to work more smoothly with the public and harmoniously with the medical officers of the district than this has done. Between July 1st of this year and Oct. 24th, a period of less than four months, 92 different local practitioners sent patients for treatment, numbering 322 cases; no difficulty has arisen in any case and no charge against the hospital of treating unsuitable cases has ever been made. The medical practitioners of the district look upon the institution as an acquisition and do their best to raise funds for its support and extension. I am quite unable to bring forward any instance in which there has been a difficulty with a local medical practitioner and the presence of so many busy medical men here to-day must tend to support this statement. Of the 344 cases admitted from Jan. 1st to Oct. 31st, 1901, 266 were free and 68 were paying cases, or about one case in five. In-patients who are able to contribute towards their cost pay from one to two guineas a week for their bed and board, whilst accident cases are all admitted free, although a few of these patients ask to be placed upon the paying list. It should be added that now and then a patient of good means can be admitted into a private room for an operation who is able to pay three, four, or five guineas for the accommodation, and who, of course, pays the fees arranged for by the

surgeon under whom he or she is admitted. It is to be regretted that at the present time these rooms are too few, and it is to be hoped that in the near future more may be provided, for such accommodation has valuable advantages to all who can utilise it.

The patients who are admitted into the hospital come from an area covered by a circle which radiates about six miles from the building; some come from far distances for special reasons. The out-patients are largely Battersea and Wandsworth people. General medical cases are neither admitted nor seen as out-patients, nor are any specific contagious or infectious diseases; such patients when they apply are referred either to their own medical men or to some hospital. 276 of these have been passed on during the 10 months of this year.

I have thus, gentlemen, briefly explained to you how this hospital came into being, and how from the wants of the neighbourhood it had in the course of years to yield part of its original constitution and to become practically a free hospital for accidents and emergencies. All its special features are worthy of your strongest support, for all are sound in principle and in this hospital have been proved sound in practice. In opening this "Victoria Wing" for out-patient work I must congratulate you upon doing so under the pleasant feeling that you have almost enough funds in hand to pay for it and to equip it. That it will be most beneficial for the work of the hospital I can vouch, for I know what good work has been done under the difficult circumstances which Mr. Lyster and his able helps have had to contend against, and with such arrangements as have been provided for the future the work must even be improved. But I must remind you that what has been done is but a promise of what in the near future has to be done, and that is the completion of the plan which has been laid before you. Until that is completed by no means rest on your oars, but pull on with all your force. The employers of labour in Battersea have through their influence upon the governors of the old hospital, where such good work was done, forced them as it were, by the weight of argument, the logic of facts, and the persistent expression of the wants of their people, to turn the hospital into a free one, with all its risks and responsibilities. The workers at the hospital are quite prepared to undertake all its professional and nursing responsibilities, and, indeed, to accept all risks, except one, and that is its financial responsibilities; these we must throw entirely upon the shoulders of the leaders of labour who by their action have brought about this change and the friends with whom they have influence. In saying this I will express my belief that we shall not do this in vain, for the interest which is taken by these leaders of labour, the tradesmen of the neighbourhood, the artisans and the gentry of the district, is so sound and earnest that we do not doubt, now that the hospital is established upon a free basis, that all will pull together with one object, and that is to get together a fund sufficient for the hospital to pay its way and to build the three wings as soon as possible.

Canon Erskine Clarke, ladies and gentlemen, I now declare this new wing, which is to be called the "Victoria Wing," open from this day—and may God bless the work which is to be done there.

## ON DUODENAL ULCER AND ITS SURGICAL TREATMENT.

By B. G. A. MOYNIHAN, M.S. LOND., F.R.C.S. ENG.,

ASSISTANT SURGEON TO THE LEEDS GENERAL INFIRMARY; CONSULTING SURGEON TO THE SKIPTON AND DISTRICT HOSPITAL AND TO THE MIRFIELD MEMORIAL HOSPITAL.

### DUODENAL ULCER.

ULCERATION of the duodenum may be acute or chronic—acute when there is a rapid destruction, tending to perforation, of the wall, and chronic when the symptoms are latent or subdued and the pathological processes which cause them are altogether passive. Possibly the two forms are often expressions of the same disease, the acute ulcer, with a rapidity and completeness of invasion that suggest an infective origin being the earlier stage of a chronic ulcer in which an attempt is made to check and to repair the ruin which has been wrought. Within the last few years duodenal

ulcers have come more closely under the observation of the surgeon. Acute ulcers have led to perforation; chronic ulcers have caused repeated attacks of hemorrhage or in their healing have so narrowed the bowel that surgical methods alone have been able to afford relief. As our capacity for dealing effectively with any of these complications has increased, so also and concomitantly have our opportunities increased.

**Position of the ulcer.**—Duodenal ulcers are generally situated in the first portion of the duodenum. Collin found in a series of 262 cases that 242 were placed in the first portion, 14 in the second, three in the third, and three in the fourth. Perry and Shaw found that in 149 cases 123 were situated in the first portion, 16 in the second, two in the third and fourth; in eight cases the ulcers were scattered. Oppenheimer states that in 81 cases 69 were situated in the first part, eight in the second, and four in the third and fourth. Ulcers in the first portion of the duodenum, then, are at least ten times more frequent than in the second. In the majority of cases the ulcers are solitary. If multiple they are usually crowded together in the first portion; but ulcers in the first portion associated with others in the second or third are recorded by Clark, Schwartz, and Dudensing. When two ulcers are present they are not infrequently opposed, those portions of the wall being affected which lie in contact. A similar opposition is, of course, not seldom observed in the stomach. The frequency of such a condition is suggestive of infection. Ulcers in various stages of activity may co-exist. An acute perforating ulcer may be found with a chronic ulcer or either with the scars and puckers of healed ulcers.

**Age.**—Patients of all ages may be affected. Oppenheimer has collected 15 cases of "melæna neonatorum," resulting from duodenal ulcer. Chvostek found ulcers present in children three hours, four days, and seven weeks old. Ulcer in the new-born child is described by Henoch, Zerschwitz, and Dusser. Krannhals relates the case of a child five years of age who died from dysentery. Ulceration was present in the duodenum; the rest of the small intestine was healthy. Haman records a case of the traumatic rupture of an ulcer in a child of 10 years of age. Clark records cases of perforation in patients 19 years and 20 years of age. Krannhals observed a case in a female 79 years old, and Merkel found an ulcer in the duodenum of an old woman, aged 94 years.

**Sex.**—All observers are agreed that men are much more frequently affected than women, though they vary in the estimates of their relative susceptibility. Taking the statistics of Collin, Perry and Shaw, Trier, Krauss, Chvostek, and Oppenheimer, all of whom have recorded over 50 cases, we have a total of 645 patients, 508 men and 137 women. We may therefore assess the proportion at four males to one female. The cause of the greater frequency of the affection in men is, with our present knowledge, quite inexplicable. Gastric and duodenal ulcers may be present at the same time. Such an occurrence has been described by Rokitsansky, Finlayson, and Oppenheimer, and is noted in the records of two of the patients upon whom I have operated.

### SYMPTOMS.

The symptoms of duodenal ulcer are chiefly characterised by their lack of ostentation. In more than half of the cases where ulceration is found at the necropsy symptoms have never been present. In 151 cases collected by Perry and Shaw in which duodenal ulceration was found post mortem there were 91 in which there were no antecedent symptoms. Every author that I have consulted emphasises the "latency" or the "torpidity" of the disease. Symptoms when present may be of an indifferent type or may resemble closely those aroused by ulcer of the stomach. The co-existence of the two forms of ulceration, gastric and duodenal, would seem from my experience to be more frequent than is generally believed, and the apparent confusion in the symptoms of certain cases may be dependent upon the simultaneous presence of both forms of ulcer. The cardinal symptoms are (1) pain, (2) hæmatemesis, and (3) melæna.

1. **Pain** is generally experienced one hour or more after the taking of food, and is referred to the epigastrium, or the right hypochondrium, or indefinitely to the upper part of the abdomen. It is variable in intensity, and though generally trivial and hardly more than a sense of discomfort or vague uneasiness, it may be acute, persistent, and at times almost intolerable. I am disposed to think that reliance may in general be placed upon the time of onset of pain after food

as indicating the position of an ulcer in the stomach or duodenum, and that, as a rule, the nearer the ulcer to the cardia the more swift is the onset of pain. The researches of Professor Birmingham on the anatomy of the stomach enable one to understand the reasons for this. Unless a duodenal ulcer is associated with a gastric ulcer the pain does not appear for from two to three or four hours. Pains radiating to the right shoulder or to the side and back are occasionally noted. It has been said that the drinking of alcoholic fluids increases or elicits the pain.

2. *Hæmatemesis* is an occasional and rather erratic symptom. Vomiting is observed approximately in one-third of the cases. In Perry and Shaw's series of 60 cases presenting symptoms hæmatemesis was present in 14. The bleeding is rarely severe. The characteristic vomiting of duodenal ulcer comes on about two hours or more after food, and bile is not seldom observed in the ejected matter.

3. *Melæna* is not improbably overlooked in a large number of cases, more especially when the intestinal hæmorrhage has been slight. When the vessel opened is large the bleeding may be copious and may induce faintness and subsequent temporary anæmia (see Case 4 of my list). If a large arterial or venous trunk is opened the hæmorrhage may be overwhelming and lethal. *Melæna* was observed in nine of Perry and Shaw's 60 cases. Oppenheimer found blood in the stools of exactly half of his patients. The examination of the stools for small quantities of blood is so unusual a research in a general hospital that we must indisputably allow that entorrhagia may often pass unnoticed.

#### THE COMPLICATIONS OF DUODENAL ULCER.

The following are the chief complications of duodenal ulcer: (1) profuse hæmorrhage; (2) perforation (acute, sub-acute, and chronic); (3) cicatricial contraction and induration and their sequelæ; (4) periduodenitis; and (5) cancer. In 20 fatal cases collected by Perry and Shaw nine patients died from hæmorrhage, eight from perforation, and three from cicatricial contraction of the duodenum or bile-duct.

1. *Hæmorrhage* is seen more frequently and in larger quantity in chronic ulcer. The vessels affected may be those in the wall of the bowel or any of the larger arteries or veins in the neighbourhood. Ulceration into the following arteries has been recorded: aorta (Stich, Grunfeld), hepatic (Broussais), gastro-duodenal (Leeds Museum), superior pancreatico-duodenal (Allchin, Wunderlich), and the pyloric, pancreatica magna, gastro-epiploica dextra, and into the vena porta (Rayer and Habershon) and the superior mesenteric vein (Warfvinge).

2. *Perforation*.—A duodenal ulcer may perforate at once and acutely into the peritoneal cavity or may slowly destroy all the coats of the bowel and lead to the formation of a localised encysted abscess. If the former, the fluid escaping from the viscus is free to run at large in the peritoneal cavity. In many of the cases, as is seen from a study of the records and was exemplified in Case 2 recorded below, a well-defined path is taken. The fluid (generally mucus more or less tinged with bile) escapes on to the upper surface of the transverse mesocolon to the right of the hillock which is formed by the fitting in of the transverse colon to the greater curvature of the stomach (see Figure).

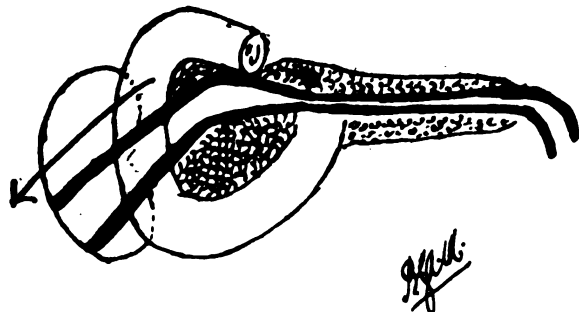

Diagram to illustrate the obliquity of the transverse mesocolon on the right side. Fluids escaping from the first portion, or the upper half of the second portion, of the duodenum gravitate to the right kidney pouch and thence to the right iliac fossa.

It therefore tends to run to the right to the hepatic flexure, and then to descend along the outer side of the ascending colon to the iliac fossa. There collecting it may cause symptoms strongly suggestive of appendicitis.

From the iliac fossa the fluid drains to the pelvis, and filling that overflows into the left iliac fossa. If an abscess forms it may be bounded by lymph, by the liver, or by intestines. Meunier describes a local abscess in his case as being bounded by the quadrate lobe of the liver, the gall-bladder, and the transverse mesocolon. Lennander relates a case where an abscess was hemmed in on all sides by intestine. The perforation of such an abscess may lead to acute septic generalised peritonitis as recorded by Planchard. Perforation of the upper portion of the duodenum may lead to subphrenic abscess. Seven cases of this kind are related in Maydl's monograph. An ulcer may destroy all the coats of the bowel and its base be formed by the liver (Keyl, Herzfelder, Collin), or by the gall-bladder (Krauss, Moynihan). An ulcer may destroy all the coats of the bowel and perforate a hollow viscus forming an "internal duodenal fistula." Rokitsky describes a case of gastro-duodenal fistula, Hoffman and Gross cases of cholecysto-duodenal fistula, Murchison, West, and Sanderson cases of duodeno-colic fistula, and Dudensing a case where the ulcer had perforated the pancreatic duct. An ulcer may destroy all the coats and lead to the formation of an abscess which bursts upon the surface of the body, forming an "external duodenal fistula," as recorded by Lumeau and Buquoy. The duodenal wall may be ulcerated through by an abscess arising from without, as in a case of lumbar abscess bursting into the duodenum close to the biliary papilla, under the care of Davies-Colley.<sup>1</sup>

3. *Cicatricial contraction and induration and their sequelæ*.—All ulcers of the duodenum in their healing tend naturally to contract. The results of such contraction will necessarily depend upon the position of the ulcer. If the ulcer has been in the first portion the narrowing of the lumen will result, as in pyloric stenosis, in dilatation of the stomach; if in the second portion there may be a dilatation of the duodenum and the stomach; or if the ulcer has invaded the bile-papilla a narrowing or obliteration of the common bile-duct and pancreatic duct. Four examples of this are quoted by Perry and Shaw, and a case is related by Swensson<sup>2</sup> in which cholecystenterostomy was performed. If the ulcer is in the third or fourth portions a dilatation of the duodenum and the stomach may result (Rewidzow). The contraction of the inflammatory material in and around an ulcer may affect the structures in the immediate neighbourhood. Collin describes a case of thrombosis and cicatricial ligature of the vena porta caused in this manner.

4. *Periduodenitis* may originate in the localised peritonitis at the base of a duodenal ulcer, from chronic perforation of an ulcer, or from causes primarily unconnected with the duodenum. Of the latter the most common is dependent upon disease of the gall-bladder or bile-ducts. Chronic pancreatitis or malignant disease of the head of the pancreas, following long-continued gall-stone irritation, may also cause the pouring out of inflammatory products by the peritoneum.

5. *Cancer*.—The cancerous transformation in chronic ulcers of the stomach is now a well-recognised pathological change. A similar condition of "ulcus carcinomatosum" has been observed in connexion with chronic duodenal ulcer. Cases are related by Ewald, Schrötter, and Mackenzie. Five cases are quoted by Perry and Shaw, but in no case is the description convincing and I should be disposed to question their claim to acceptance.

#### THE SYMPTOMS OF ACUTE PERFORATION.

The symptoms of an acute perforation differ at the first but little, if at all, from those which follow the perforation of a gastric ulcer. There is the same sudden, intolerable, and overwhelming pain; there are rigidity and tenderness of the abdomen and profound collapse. In duodenal ulcer there is said to be a disposition to localise the pain in the right hypochondrium rather than in the epigastrium, but the records of published cases, and of my own cases, do not support this. As in gastric ulcer, so in duodenal, the sudden, terrible pain may induce a collapse which proves almost immediately fatal. A few years ago I performed a post-mortem examination for the coroner on a young man who had died suddenly. I found a perforation of the duodenum just beyond the pylorus. The relatives, when pointedly asked, affirmed that the patient had never suffered from any gastric or intestinal disorder.

After the first shock has passed the symptoms and signs

<sup>1</sup> Guy's Hospital Reports, 1893, p. 573.

<sup>2</sup> Hygela, Stockholm, 1888.

of gastric and duodenal perforation differ in their development. When the ulcer is in the stomach the signs are those of general peritoneal inflammation; when the ulcer is duodenal the course taken by extravasated fluids leads to a more acute and an earlier involvement of the peritoneum on the right side and in the right iliac fossa. The clinical picture of appendicitis is copied with such accuracy that in the 49 recorded cases tabulated in my list, in 18 the first incision was made over the appendix, after a diagnosis of acute appendicitis had been made. In the final stage the peritoneal infection is universal.

#### TREATMENT.

The medical treatment of duodenal ulcer should be carried out with the same persistence and care as are needed in treating ulcers of the stomach. Surgical treatment may be called for: (1) when an acute ulcer perforates; (2) when subacute or chronic perforation leads to periduodenal or subphrenic abscesses; (3) in chronic ulcer when pain and gastro- or enterorrhagia are persistent and disabling; and (4) when cicatricial contraction and induration or periduodenitis have caused narrowing of the calibre of the gut and dilatation of the stomach or of the stomach and that part of the duodenum behind the stricture.

1. *When an acute ulcer perforates.*—There are on record 49 cases of operation for acute perforation of a duodenal ulcer. I have operated upon two cases, making a total of 51. In 18 of these cases a diagnosis of appendicitis was made; in two cases only, that recorded by Perkins and Wallace and in my first case, was a correct diagnosis achieved. The following are the notes of my two cases:—

CASE 1.—The patient, a male, aged 44 years, was admitted under my care into the Leeds Infirmary on April 24th, 1900, and was sent by Mr. H. de P. Veale of Drighlington. The patient was a morose individual of deficient intelligence, and a history was therefore difficult to elicit. Symptoms had been present for 18 months; the chief of them was pain, experienced after food, two, three, or four hours after, beginning in the right hypochondrium and spreading upwards and downwards. Blood had been observed when the patient vomited; vomiting was frequent but irregular, occurring sometimes within half an hour of a meal, sometimes four hours after. There was no melena. The patient was kept under observation until May 25th. His pain was evidently most severe and directly influenced by the taking of food. A diagnosis of duodenal ulcer which had been made by Mr. Veale was confirmed and gastro-enterostomy was advised. On the 25th the man became suddenly worse. Pain was complained of over the whole abdomen which was tight, and the abdominal muscles barely moved with respiration. The pulse was 128, the respirations were 28, and collapse was pronounced. Clearly a perforation had taken place. The abdomen was opened and a duodenal ulcer with a perforation about three-quarters of an inch in diameter was found at the beginning of the second portion of the gut. There was commencing peritonitis. The stitches which were introduced to close the ulcer held very imperfectly. After stitching the gut seemed narrowed to at least half its diameter. A gastro-enterostomy was therefore done, a Murphy button being used. The abdomen was cleansed by sponging and a tube with gauze was passed down to the ulcer. The patient never rallied from his collapse and died on May 26th.

CASE 2.—The patient, a male, aged 25 years, was admitted into the Leeds Infirmary on June 18th, 1901, under the care of Mr. W. H. Brown, who kindly gave me charge of the case. The patient, a sturdy, robust labourer, stated that for about four weeks before admission he had experienced pain after food and had vomited. The pain came on either immediately after the taking of food or about from three to four hours subsequently. Vomiting occurred almost immediately after the end of a meal. At 5 p.m. on June 18th, while climbing a ladder, he felt a sudden acute pain in the upper part of the abdomen in the middle line. He reached the top of the ladder, deposited his load, and descended. On reaching the ground he fell and doubled himself up in agony. He was seen by Dr. L. A. Rowden of Roundhay, who sent him at once in his carriage to the infirmary. On admission the patient was profoundly collapsed. The abdomen was exquisitely tender and the muscles formed so rigid a protecting splint that nothing could be felt. Liver dulness was present. There were persistent efforts at vomiting, but little was brought up except frothy mucus. The pulse was 128; the skin was cold. The patient was in the

extremity of anguish. In answer to questions he could utter barely two or three words at each expiratory gasp. Clearly a catastrophe had occurred, and our tentative diagnosis was one of perforated gastric ulcer. I opened the abdomen at 9.50 p.m. (three hours and 50 minutes after perforation). On cutting through the peritoneum a few bubbles of odourless gas and froth escaped. A thin slightly turbid yellowish fluid welled up into the wound. The stomach was examined and found to be intact. A perforation was found equal to a No. 8 or No. 9 catheter in diameter on the anterior wall of the duodenum about one inch from the pylorus. From the opening a yellowish, thick, glairy, bile-stained fluid escaped. The opening was rapidly stitched up by a single continuous suture applied vertically from above downwards and then returning from below upwards. The stitch held quite readily. The abdomen was flushed out thoroughly. The right kidney pouch, the right iliac fossa, and the pelvis contained a turbid yellowish fluid. The left kidney pouch and the left iliac fossa were clean. A drainage tube was placed in the pelvis. A most curious sensation was experienced in handling the omentum and intestines, which, as I remarked at the time, suggested that the intestines had been oiled. The return of the omentum and some small intestine which escaped during the flushing was thereby rendered unusually difficult. During the operation the patient lay on a heated table, was swathed in wool and flannel bandages, and had one-tenth of a grain of strychnine administered hypodermically twice. His condition after the operation was satisfactory. One-twentieth of a grain of strychnine was given hypodermically every four hours for three days. No fluid was allowed by the mouth for 24 hours, sips of water and soda-water being then given. Rectal injections of saline solution (10 ounces) were given every six hours. The drainage-tube was removed in 36 hours. Both wounds healed well and on the nineteenth day the patient sat up. His recovery was quite uneventful.

The accompanying table (Table I.) shows all the cases of acute perforation which have been operated upon up to July, 1901.

In carrying out an operation for a perforated duodenal ulcer the utmost speed consistent with safety and thoroughness is desirable. The abdomen is opened through the right rectus muscle about half an inch or one inch from the median line. Odourless gas escapes as soon as the peritoneum is cut. The perforation, if on the anterior surface, is readily seen, and from the opening bubbles of froth, bile-stained mucus, or altered food will issue. If on the lateral surface the exact position of the ulcer may be discovered by compressing the stomach or duodenum so as to force some of their contents through the rupture. As in the stomach, two ulcers may be found to have perforated, as is recorded by Biggs. As soon as the ulcer is exposed the perforation should be closed by a single or double continuous Lembert suture of silk or fine Pagenstecher thread. The excision of the ulcer is unnecessary and is harmful in so far as it wastes moments which are precious. The rupture being securely closed the peritoneal cavity is cleansed. This should be done freely and methodically. A glass drainage-tube should be introduced into the pelvis by a separate incision above the pubes, and the flushing is then begun. The immediate neighbourhood of the duodenum is first flushed, then, in order, the space between the liver and diaphragm on both sides of the suspensory ligament, the interval between the liver and the transverse colon, the right kidney pouch, the right iliac fossa, the pelvis, the left kidney pouch, and left iliac fossa. The cleansing is best effected by using a long indiarubber tube with a funnel, the soft tubing being readily passed to any spot desired. Saline solution at a temperature (taken with the thermometer) of 105° F. is used. When the returning fluid from all areas is clear the wound may be closed. There is no need to empty by sponging the peritoneal recesses. The usual routine as to the administration of strychnine in large doses hypodermically, the use of a heated table, warm clothing, &c., should be rigidly observed. The value of large doses of strychnine in anticipating and preventing shock does not seem to be appreciated. In a recent case of double primary amputation on the right side at the hip-joint, and on the left in the middle of the thigh, I gave 45 minims of liquor strychnine hypodermically in the three-quarters of an hour that the patient was on the operating table. The patient recovered, and neither he nor any other patient to whom I have administered Gargantuan doses

TABLE I.—OPERATIONS FOR ACUTE PERFORATING DUODENAL ULCER.

No. of case.	Recorder.	Sex.	Age (years).	History.	Condition found and nature of operation.	Result.	Remarks.	Reference.
1	Mackenzie (operator, Sidney Jones).	M.	35	Indefinite epigastric pain, one week; sudden acute pain; vomiting and collapse; alcoholia.	General peritonitis (cause doubtful). Operation at the end of the second day.	Died in a few hours.	Duodenal ulcer found at necropsy just beyond the pylorus.	THE LANCET, Dec. 1st, 1888, p. 1092.
2	Mackenzie (operator, John Croft).	M.	31	Acute attack resembling intestinal obstruction diagnosed as appendicitis and general peritonitis.	General peritonitis of doubtful origin. Operation on the third day.	Died in a few hours.	Duodenal ulcer found at necropsy immediately beyond the pylorus.	THE LANCET, Dec. 1st, 1888, p. 1090.
3	Bolfin.	M.	29	Sudden seizure; abdominal pain, vomiting, and distension; diagnosis of perforative peritonitis.	General peritonitis. Operation in 90 hours. A cavity containing two quarts of serous fluid was found beneath the liver.	Died on the same day.	—	Congrès Français de Chirurgie, 1892.
4	Lockwood.	M.	28	Sudden, violent pain while drinking tea; later fecal vomiting and tympanites.	Peritonitis; gas and pus evacuated; drainage. Operation in 80 hours.	Died in seven hours.	Perforation of the duodenum found at the necropsy.	Transactions of the Medical Society of London, 1892.
5	Lockwood.	M.	41	Slight previous indigestion. While at work a sudden seizure with abdominal pain and vomiting.	Septic peritonitis; drainage.	Died in ten hours.	Perforation of the duodenum found post mortem.	Transactions of the Medical Society of London, 1892.
6	Pearce Gould.	F.	27	Sudden attack of pain in the right hypochondrium, soon becoming general; vomiting; tympanites; no loss of liver dulness.	General peritonitis; incision below the umbilicus allowed the escape of fluid; then incision above the umbilicus revealed a perforation. Operation in 24 hours; ulcer excised.	Died in six hours.	Suture firm, but general peritonitis.	Middlesex Hospital Reports, 1893.
7	Perry and Shaw (operator, W. H. A. Jacobson).	M.	21	Sudden attack of acute abdominal pain in the lower part; vomiting and collapse.	Large quantity of dark brown acid fluid with fecal odour evacuated.	Died in four hours.	At necropsy a perforation was found in the first part of the duodenum on the anterior surface. A second ulcer was found immediately opposite.	Guy's Hospital Reports, 1893.
8	Lockwood (J. Langton's patient).	M.	56	Brought to hospital with abdomen tympanitic and the signs of acute intestinal obstruction.	Peritonitis; purulent and fecal fluid evacuated.	Died in a few hours.	Ulcer of the duodenum was found at the necropsy; suture could have been easily performed.	THE LANCET, Oct. 27th, 1894, p. 968.
9	Lockwood.	M.	28	Sudden pain in the abdomen while ascending an omnibus; vomiting. Admitted to hospital on seventh day with intestinal obstruction. Coils of intestine were seen to be contracting.	Purulent peritonitis in the pelvis, irrigation, drainage. Operation in 150 hours.	Died in 54 hours.	Ulcer of the duodenum found post mortem, with local peritonitis and abscess. A second ulcer was found in the stomach.	THE LANCET, Oct. 27th, 1894, p. 968.
10	Lockwood.	M.	61	Long history of gastric ulcer; no hæmatemesis; sudden pain in the right hypochondrium; collapse.	Operation in four and a half hours. Perforation was found in the anterior wall of duodenum; this was sutured.	Died in six days.	A second ulcer was found on the posterior wall of the duodenum.	THE LANCET, Oct. 27th, 1894, p. 968.
11	Eve.	M.	28	Sudden abdominal pain while lifting; vomiting immediately; on third day this became fecal.	Operation in 62 hours; sero-pus was evacuated. An ulcer as big as a florin was found one inch from the pylorus; edges pared; omental graft made.	Died in two hours.	No necropsy.	THE LANCET, Nov. 10th, 1894, p. 1092.
12	Dean.	F.	27	Epigastric pain for a fortnight; sudden abdominal pain; vomiting and collapse.	Operation in 30 hours. Incision was made below the umbilicus, then prolonged upwards; gas was seen issuing from near the duodenum. Ulcer was seven inches from the pylorus and was sutured.	Recovered.	Nothing given by the mouth for 17 days. After two months an attack of intestinal obstruction; operation on third day; death.	Transactions of the Medical Society of London, 1894.
13	Brissaud.	M.	35	Sudden abdominal pain and vomiting; tympanites; collapse.	Operation in 51 hours. Incision over the appendix gave issue to fecal matter; general peritonitis; drainage.	Died in a few hours.	Perforation was found just beyond the pylorus.	Collin: Thèse de Paris, 1894.
14	Bryant.	M.	—	After a debauch a sudden attack of pain in the right side of the abdomen.	Operation in 53 hours, as for appendicitis; pus and milky fluid were evacuated; drainage.	Died.	A perforated duodenal ulcer was found at the necropsy. A sac around the cæcum contained milk and food.	Medical Record, 1896.

TABLE I.—OPERATIONS FOR ACUTE PERFORATING DUODENAL ULCER—(Continued).

No. of case.	Recorder.	Sex.	Age (years).	History.	Condition found and nature of operation.	Result.	Remarks.	Reference.
15	Sheild.	M.	20	Sudden severe pain while at the theatre. No vomiting until second day; tympany, pain, and tenderness over cæcum. An opinion was expressed that the case was one of appendicitis.	Operation in 60 hours. Odourless gas; thin pus and lymph in peritoneum. Lavage.	Died in 24 hours.	A perforation was found in the anterior wall of the first portion of the duodenum.	THE LANCET, May 11th, 1895, p. 1169.
16	Sheild.	M.	23	A sudden attack of pain and vomiting three years before. Present attack began with acute pain and vomiting; tympanites.	Operation in 120 hours. Odourless gas and thin pus escaped. The jejunum was incised; lavage; drainage.	Died in 22 hours.	Necropsy revealed a duodenal ulcer half an inch from the pylorus.	THE LANCET, May 11th, 1895, p. 1169.
17	Bolton.	M.	28	The patient was an alcoholic. Sudden abdominal pain and vomiting, followed by tympanites.	General peritonitis. Irrigation; drainage.	Died in three days.	Ulcer in third portion of the duodenum, with pancreas forming the base.	Medical Record, 1900, p. 495.
18	Bolton.	M.	35	The patient was an alcoholic. History of similar attack 13 years before. Abdominal pain and vomiting for a few days; tender abdomen.	Diagnosis of appendicitis. Incision over appendix revealed general peritonitis. Drainage.	Died in a few hours.	Ulcer in first portion; periduodenitis.	Medical Record, 1900, p. 495.
19	Festal.	M.	56	A long history of gastritis, diarrhoea, and melæna. An acute attack of pain four hours after food, vomiting, and collapse. Tumefaction on third day in iliac fossa.	Diagnosis of appendicitis. Operation in 66 hours. Incision over appendix; douche and drainage.	Died in nine hours.	Ulcer just below the pylorus occupying two-thirds of the circumference of the gut. Healed ulcer of the stomach.	Journal de Médecine de Bordeaux, 1895.
20	Herczel.	M.	33	Sudden pain in the right hypochondrium; collapse.	Operation in 25 hours. Purulent fibrinous peritonitis. Perforation found and sutured.	Recovered.	Attack of bronchitis during convalescence.	Pagenstecher: Deutsche Zeitschrift für Chirurgie, 1899, p. 556.
21	Bolton.	M.	35	A hard drinker. Sudden severe abdominal pain without vomiting; diagnosis of appendicitis.	Operation in 20 hours; general peritonitis.	Died in 24 hours.	Necropsy showed a perforating ulcer in the duodenum one and a quarter inches from the pylorus, and a second ulcer lower down.	Medical Record, 1900.
22	Warren.	M.	52	An attack of acute epigastric pain six years previously; ill ever since. Acute attack of severe pain about pylorus, tympanites, and vomiting; appendicitis diagnosed.	Operation on fourth day. The intestines were distended and covered with lymph. Ulcer in duodenum was sutured.	Died in three days.	No necropsy.	Boston Medical and Surgical Journal, 1895.
23	Dunn.	M.	—	Sudden epigastric pain while at work followed by vomiting; tympanites and loss of liver dulness.	Operation in 30 hours. Perforation in the anterior wall of the first portion of the duodenum. Gas and yellowish fluid were evacuated. A second laparotomy was necessitated owing to return of symptoms; adhesions only found; mural abscess.	Recovered.	—	Brit. Med. Jour., vol. 1., 1896.
24	Länderer and Glucksmann.	M.	50	10 or 15 years' pain, hæmatemesis, and melæna. Eight months before patient had had all the symptoms of perforation, but at the operation no ulcer was found; blood-stained fluid was seen to escape from near the duodenum. Admitted with peritonitis.	General septic peritonitis.	Died.	Ulcer of second part found at necropsy.	Mittheilungen aus dem Grenzgebiete der Medizin und Chirurgie, vol. 1., 1896.
25	Banret and Lardennois.	M.	24	Acute epigastric pain at the end of a meal. Diagnosis lay between appendicitis and duodenal perforation.	Operation in 19 hours. A perforation on the anterior surface of the duodenum near the pylorus was sutured; peritonitis.	Died in 20 hours.	Suture tight.	Bulletin de la Société Anatomique de Paris, 1897.
26	Lardennois.	M.	26	Intense pain on the left side of the abdomen during exertion; vomiting was blood-stained and bilious; diagnosis, appendicitis.	Operation in 56 hours. Incision over appendix; peritonitis found; drainage.	Died in 30 hours.	A perforation was found in anterior wall near pylorus.	Bulletin de la Société Anatomique de Paris, 1897.

TABLE I.—OPERATIONS FOR ACUTE PERFORATING DUODENAL ULCER—(Continued).

No. of case.	Recorder.	Sex.	Age (years).	History.	Condition found and nature of operation.	Result.	Remarks.	Reference.
27	Soligoux.	M.	—	A sudden attack of pain and colic.	Perforation of the first portion of the duodenum. Suture.	Died in 12 hours.	—	Bulletin de la Société Anatomique de Paris, 1897.
28	Beausse.	M.	—	A policeman; sudden attack of pain while on duty. Diagnosis of biliary colic; 30 hours after the onset vomiting and distension; diagnosis of appendicitis or intestinal obstruction.	Operation in 48 hours. General peritonitis discovered.	Died in one hour.	Necropsy revealed a perforation just beyond the pylorus.	Journal de Médecine de Paris, 1897.
29	Lennander.	F.	25	History of gastric troubles. Gastric pain was followed by general tenderness and tympanites; diagnosis of appendicitis.	Operation in four days. Incision made over the appendix. General peritonitis.	Died in four days.	Necropsy revealed a perforation close to pylorus. A second ulcer was present.	Mittheilungen aus dem Grenzgebiete der Medizin und Chirurgie, 1898.
30	Lennander.	F.	34	Long history of gastric troubles; pain, vomiting, and rapid pulse.	Operation 15 hours after. A perforation thought to be in the stomach near the lesser curvature was sutured.	Died in 24 hours.	A perforation was found in the first portion of the duodenum. Three ulcers in the stomach.	Mittheilungen aus dem Grenzgebiete der Medizin und Chirurgie, 1898.
31	Lennander.	M.	37	Long history of gastric troubles; sudden attack of pain when sitting up in bed; vomiting; diagnosis of duodenal ulcer or appendicitis.	Operation 60 hours after. A perforation was found in the anterior superior portion of the duodenum near the pylorus.	Died in 26 hours.	Fibrous peritonitis; an abscess between the stomach and the colon.	Mittheilungen aus dem Grenzgebiete der Medizin und Chirurgie, 1898.
32	Schwartz (operator, Rochard).	M.	46	During exertion a sense of injury and abdominal pain; diagnosis of intestinal obstruction.	Operation in five days. General peritonitis, with pus and lymph. On the superior surface of the duodenum near the pylorus a large ulcer was sutured.	Died in two hours.	—	Bulletin et Mémoire de la Société de Chirurgie, 1898.
33	Schwartz (operator, Guinard).	F.	30	History of indigestion; sudden pain during breakfast; diagnosis of perforated gastric ulcer.	Operation after 28 hours. Incision above the umbilicus; escape of gas, bile, and pus. A perforation was found in the right side of the second portion of the duodenum. Opening sutured; drainage.	Died in 14 hours.	Necropsy showed a second ulcer lower down.	Bulletin et Mémoire de la Société de Chirurgie, 1898.
34	Schwartz (operator, Sieur).	M.	23	History of gastric ulcer; sudden attack after drinking coffee; distension, pain, and vomiting.	Operation after 48 hours. General peritonitis; perforation in posterior superior wall of first portion; sutures tore through. The ulcer was walled off by sutures in the omentum.	Died in 36 hours.	General peritonitis; no other lesion.	Bulletin et Mémoire de la Société de Chirurgie, 1898.
35	Wanach.	M.	22	Acute attack three hours after a meal, pain, tenderness, &c.; diagnosis of appendicitis.	Operation in 15 hours. Incision over the appendix; general peritonitis; appendix removed. A second incision showed a perforation in the anterior wall of the first portion; this was sutured.	Recovery after serious and prolonged illness.	Wound was packed with iodoform gauze, and did not heal completely for three months.	Archiv für Klinische Chirurgie, 1898.
36	Whipple.	M.	38	History of pain three hours after food; sudden acute attack of pain; collapse and distension.	Operation after 72 hours. A perforation was found in the anterior wall of the duodenum near the pylorus.	Died in eight hours.	Pus between the liver and diaphragm.	Brit. Med. Jour., vol. ii., 1898.
37	Routier.	M.	30	History of indigestion; sudden severe pain during exertion; abdomen painful, distended.	Operation after 27 hours. Pus in the pelvis and on the right side; general peritonitis.	Died in nine days from pneumonia.	A perforation in the duodenum was partly closed in by adhesions.	Bulletin et Mémoire de la Société de Chirurgie, 1899.
38	Taylor.	F.	17	Indefinite abdominal pains, looked upon as due to appendicitis; collapse.	Operation in 12 hours. Incision over appendix. Perforation was found in the anterior wall of the third portion. Purse-string suture, supported by others; drainage.	Recovery; suppuration along drainage tracks.	—	North Carolina Medical Journal, 1899.
39	Erdmann.	M.	30	Sudden pain in the abdomen, followed by shock and toxic symptoms; diagnosis of appendicitis.	Operation in 36 hours. A perforation was found in the first portion of the duodenum.	Died in a few hours.	—	Medical Record, 1899.
40	Erdmann.	M.	40	Seized with pain while at work; shock; toxic symptoms; collapse.	Operation in 20 hours. Perforation in the first portion of the duodenum.	Died in a few hours.	—	Medical Record, 1899.

TABLE I.—OPERATIONS FOR ACUTE PERFORATING DUODENAL ULCER—(Continued).

No. of case.	Recorder.	Sex.	Age (years).	History.	Condition found and nature of operation.	Result.	Remarks.	Reference.
41	Brooks.	M.	29	The patient was an alcoholic. For three years he had had gastric trouble; after a debauch he had had abdominal pain, vomiting, and distension; diagnosis of appendicitis and peritonitis.	Operation from one to two days after attack. The appendix was removed and one quart of fluid escaped.	Died in 30 hours.	Perforation was found in the first portion of the duodenum.	Medical Record, 1899.
42	Weir.	M.	30	History of gastric troubles; sudden epigastric pain, vomiting, and prostration; distension and tenderness.	Operation after four days. A perforation found in the anterior superior wall of the duodenum close to the pylorus was sutured.	Died in a few hours.	—	Medical Record, May 5th, 1900.
43	Johnson.	M.	27	The patient was an alcoholic; sudden severe pain in the upper abdomen; chill.	Operation in 10 hours. Bile-stained fluid escaped. A perforation found on anterior surface of descending portion was sutured; flushing.	Recovered.	—	Annals of Surgery, 1899, p. 624.
44	Elliot.	M.	—	No history.	Ulcer at the back of the duodenum was stitched with difficulty.	Died from hæmorrhage.	—	Boston Medical and Surgical Journal, 1900.
45	Elliot.	M.	—	No details.	Operation on fifth day. General peritoneal infection. Ulcer was sutured.	Died on third day.	—	Boston Medical and Surgical Journal, 1900.
46	Perkins and Wallace.	M.	52	Epigastric pain of three days' duration, suddenly increased; a diagnosis of perforated duodenal ulcer.	Operation in 10 hours. An opening was found at the junction of the first and second portions. Suture; drainage.	Recovered.	—	THE LANCET, Feb. 17th, 1900, p. 468.
47	Bolton.	M.	20	Seven months' history; sudden severe pain in the right side; tenderness over the appendix; diagnosis of appendicitis.	Operation in 20 hours. Incision over the appendix allowed escape of odourless gas and fluid.	Died in 24 hours.	Necropsy revealed a perforation just beyond the pylorus.	Medical Record, March, 1900.
48	Bolton.	M.	45	The patient was an alcoholic. Four years previously an attack of severe pain in right side; distension; tenderness; diagnosis of appendicitis.	Operation in 22 hours. Incision over the appendix; escape of turbid serum; flushing; drainage.	Died in seven days.	Necropsy revealed a perforation in the anterior wall just beyond the pylorus.	Medical Record, March, 1900.
49	Christy Wilson.	M.	48	Several years of indigestion; sudden seizure of pain while at work.	Operation after 28 hours. Immediate escape of bile-stained mucus. A perforation found about one inch from the pylorus. General peritonitis; two layers of sutures.	Recovered.	—	THE LANCET, June 15th, 1901, p. 1681.

In compiling this list I have disallowed certain cases which have been accepted by other writers. These are Bolton's first case (there is no post-mortem record); Lennander's third case (a case of chronic perforation with the formation of periduodenal abscesses); and Routier's case of chronic perforation with abscess. The total number, including my own two cases related above, is 51 with eight recoveries.

had any symptoms of poisoning. In my first case it was obvious that the duodenum at the point of ulceration was so narrowed by the suturing that a marked stricture of the bowel would inevitably result, if the patient survived. I therefore gave an alternative route from the stomach by performing gastro-jejunostomy. This procedure is one to which I desire especially to call attention, as it will doubtless prove, in some few cases, of the greatest service. In Case 34 in the table related by Schwartz (operated upon by Sieur) and in Festal's case, where the ulcer occupied two-thirds of the circumference, it would have been an advantage. If, as rarely happens, there is difficulty in effecting a complete suture, or if, as in Landerer and Glucksmann's case, the opening of the ulcer cannot be found, a new outlet from the stomach would give some measure of rest to the duodenum and thereby facilitate healing. Omental grafts or flaps may be used to secure the "walling-off" of the ulcer.

2. When subacute or chronic perforation leads to periduodenal or subphrenic abscess.—Periduodenal abscesses are opened through the abdominal wall in front, subphrenic through the anterior or lateral walls of the abdomen, or through a low intercostal space. If the perforation is discovered, as in the third case related by Lennander, it should be closed by suture, and a drainage tube should be passed

down to the abscess cavity, and should be left in for two or more days. The following case has been under my care.

CASE 3.—The patient, a female, aged 29 years, was admitted into the Leeds Infirmary on Sept. 29th, 1900. She complained of having had several acute attacks of pain, accompanied by vomiting, during the last five years. The first attack occurred after her confinement, and lasted for five days. There was blood in the vomit on that occasion, and blood had been noticed irregularly since. The motions had never been observed. The attacks had appeared without apparent cause. There had always been a sense of discomfort after meals, appearing from one to four hours after food. The diet had not been a full or a generous one for the last two or three years, and the patient was said to have been "fanciful" in her selection of food. There had never been jaundice, and no alteration had been observed in the condition of the urine. On admission the patient seemed, and looked, to be quite well. She was kept in bed and given a light diet. On Oct. 4th she had an attack similar to those from which she had previously suffered. The temperature was 101° F. and the pulse was 100. Vomiting occurred at intervals for three days; there was no hæmatemesis. The right upper quadrant of the abdomen was exquisitely tender and the muscles

formed so rigid a defence that examination was impossible. Pain above and a little to the right of the umbilicus was severe. The patient looked ill and anxious. The motions were normal. After the attack had subsided the stomach was more carefully examined and found to be dilated, reaching three-quarters of an inch below the umbilicus. A diagnosis of pyloric ulcer with perigastritis was made. On Oct. 12th the abdomen was opened between the linea semilunaris and the middle line. Many adhesions were

and left the hospital, the wound being entirely healed on Nov. 5th.

3. *When pain and gastorrhagia or enterorrhagia are persistent and disabling.*—Case 4 in my list is an admirable example of this form. The treatment of such cases is by the performance of gastro-enterostomy. The amount of food passing over the ulcer is reduced considerably (the greater part going by the new opening), and the rest so secured permits the healing of the ulcer.

TABLE II.—CASES OF CHRONIC DUODENAL ULCER.

No. of Case.	Date.	Sex.	Age (years).	Symptoms and description.	Condition found and nature of operation.	Result.	Remarks.
1	January, 1900.	F.	41	At the age of 16 years the patient had had an illness, attended with the vomiting of blood, on one occasion in large quantity. She had had pain after food ever since, at times better, at times worse. The diet had been carefully and rigidly supervised. In June, 1899, pain began to be much more acute, and vomiting, which before had been inconstant, now became frequent. Large quantities (four pints) were vomited. On examination of the abdomen a large contracting stomach was seen. Nothing abnormal was felt over the pylorus.	Thickening at the pylorus, and along the first portion of the duodenum, with contraction and many adhesions. The adhesions were carefully broken down, and gastro-enterostomy was performed.	Recovered.	Quite restored to health; eats well and suffers no pain.
2	January, 1900.	M.	55	Dyspepsia for 10 years; periodic seizures of copious vomiting at intervals of from 24 hours to three weeks.	Enormous stomach; thickening at the pylorus and along the first portion of the duodenum; cicatricial contraction very marked; adhesion to liver. Gastro-enterostomy was performed on two occasions, first with Laplace's forceps and then with Murphy's button.	Recovered.	Seen in July, 1901; had gained two and a half stones and could eat perfectly well.
3	Feb. 16th, 1901.	F.	31	For some years there were pain after food and diarrhoea; pain came on about half-an-hour after food and lasted for three hours or more; hæmatemesis.	Three ulcers were found, two in the stomach near the lesser curvature, one in the first part of the duodenum with considerable induration. Posterior gastro-enterostomy.	Recovered.	Complete relief.
4	March 3rd, 1901.	M.	30	The patient was sent to me by Mr. G. Millhouse and Mr. G. P. Anning with a diagnosis of duodenal ulcer; symptoms had persisted for five or six years. There were pain in the epigastrium after meals and vomiting; had attacks of faintness and prostration, followed by melæna and anaemia.	An ulcer was found in the first part of the duodenum with many adhesions; small scar of gastric ulcer on the posterior surface of the stomach. Gastro-enterostomy.	Recovered.	Complete relief; on May 31st had gained 12 pounds.

found around the pylorus, duodenum, and gall-bladder. On separating these an abscess cavity holding three ounces of pus was discovered. It lay between the liver and duodenum. The duodenal wall was thickened and indurated and there was an ulcer at the junction of the first and second portions which had perforated and caused a localised periduodenal abscess. The liver, gall-bladder, and bile-ducts were intact. A drainage-tube with a sterilised gauze wick was introduced. The patient did well

4. *When cicatricial contraction and induration or periduodenitis are present.*—In such cases the symptoms are those of dilated stomach and a diagnosis of pyloric narrowing will generally be made. Gastro-enterostomy will give complete relief. A case of ulcer, causing stenosis, in the fourth portion of the duodenum is related by Rewitzow. Gastro-enterostomy was performed. My experience extends to four cases, the notes of which are given in Table II.

Leeds.

## EXPERIMENTAL HÆMOGLOBINURIA CAUSED BY A BACTERIAL TOXIN.

By CHARLES TODD, M.D., D.P.H. CANTAB.,  
ASSISTANT BACTERIOLOGIST, ANTITOXIN DEPARTMENT, JENNER  
INSTITUTE OF PREVENTIVE MEDICINE.

(Preliminary Communication.)

It is well known that the injection into the blood-stream of certain substances which have a solvent effect on the red blood corpuscles gives rise to the appearance of hæmoglobin in the urine. This has been described as the result of the injection of certain simple chemical bodies (e.g., distilled water, glycerine, &c.), and of the sera of other animals. Since the discovery of tetanolysin by Ehrlich a series of hæmolysins has been described as produced by various organisms—e.g., bacillus pyocyaneus,<sup>1</sup> staphylococcus aureus and albus,<sup>2</sup> bacillus diphtheriae, micrococcus tetragonus, streptococcus pyogenes,<sup>3</sup> and bacillus typhosus,<sup>4</sup> &c.

<sup>1</sup> Bulloch and Hunter: Centralblatt für Bakteriologie, 1900, Band xxviii., p. 865.

<sup>2</sup> Neisser and Wechsberg: Zeitschrift für Hygiene, 1901.

<sup>3</sup> Lubenau: Centralblatt für Bakteriologie, 1901, Band xxx., p. 356.

<sup>4</sup> E. Levy and Prosper Levy: Centralblatt für Bakteriologie, 1901, Band xxx., p. 405.

These organisms, however, are all pathogenic for animals, and their hæmolytic action, which in most cases is comparatively feeble, is masked by other more obvious pathogenic effects. A more suitable organism for the study of experimental hæmoglobinuria is found in the bacillus megatherium, which, when grown in suitable media, gives rise to the formation of products which are very powerfully hæmolytic for the corpuscles of certain animals without causing death or serious illness from other pathogenic effects.

The hæmolytic action of the bacillus was first observed in the course of some experiments with a sample of papain in powder. It was found that the powder contained a strongly hæmolytic bacillus which on isolation proved to be the bacillus megatherium. A culture of the same bacillus was obtained from hay infusion, and these two races, together with one of the bacillus megatherium (De Bary) obtained from Kral of Prague were used in the following experiments. These three, though showing slight cultural differences, appear to be all races of the same bacillus. Parallel experiments were done with the three races, which were grown in alkaline broth in Erlenmeyer flasks at 37° C., and the hæmolytic power of the cultures was tested daily on a 5 per cent. suspension of guinea-pigs' washed corpuscles in 0.75 per cent. saline.

*Formation of the hæmolysin.*—The formation of the hæmolysin, which is in the main extra-bacillary, begins

under these circumstances between the second and third days, the amount rapidly rising to a maximum on the sixth or seventh day; after this it slowly decreases. The temperature exercises an important action, and so far the best results have been obtained at from 35° to 37° C. Oxygen is essential, and though some growth takes place anaerobically there is no formation of hæmolyisin, hence a much stronger lysin was obtained by growing the bacillus in shallow layers of broth in Erlenmeyer flasks than in test tubes.

A somewhat high degree of alkalinity of the medium appears to favour the production of the lysin, and the best results were obtained with ordinary peptone beef bouillon, which was made just alkaline to litmus, and then normal caustic soda was added in the proportion of seven cubic centimetres per litre. Parallel experiments were made by growing the same bacillus (1) in six flasks of broth made just alkaline to litmus; and (2) in six flasks of the same broth with the addition of seven cubic centimetres of normal caustic soda per litre. After nine days in the incubator the cultures were filtered through a Pasteur-Chamberland filter and tested on guinea-pigs' corpuscles, with the result that the filtrate in the first case hæmolyzed six times its volume, and the more alkaline filtrate 40 times its volume of the suspension, showing that the formation of the lysin was approximately seven times as great in the highly alkaline broth.

*Action of the lysin on the corpuscles of various animals.*—The red blood corpuscles of different species show a very great difference in the extent to which they are affected by the lysin, those of the guinea-pig being found the most sensitive of the corpuscles tried, one cubic centimetre of the filtered culture completely hæmolyzing about 50 cubic centimetres of a 5 per cent. suspension of these corpuscles in an hour at 37° C. The corpuscles of man and of the monkey are also highly sensitive. The corpuscles of the sheep, goat, pig, and bullock are moderately sensitive, those of the dog, rat, rabbit, fowl, and sparrow are very slightly affected, and those of the donkey and horse are practically unaffected.

*Nature of the lysin.*—Megatheriolysin resembles the toxins of diphtheria and tetanus in being mainly extra-bacillary, even young cultures filtered through a Pasteur-Chamberland filter being strongly hæmolytic. It is very unstable at ordinary temperatures, but much less so than tetanolyysin according to Madsen's<sup>5</sup> description of the latter. At 0° C. it is comparatively stable. A filtered culture kept in the ice-safes for 14 days was found to be almost unaltered, but one kept at about 20° C. for three weeks had gone down to one-eighth of its original strength. Heating to 56° C. for 30 minutes completely destroys the hæmolytic action of filtered cultures. Heating for five minutes at 100° C. does not entirely destroy the action of unfiltered cultures but very nearly so.

*Existence of an anti-body in normal serum.*—The anti-hæmolytic action of normal serum towards a bacterial hæmolyisin was first pointed out by Ehrlich<sup>6</sup> in the case of tetanolyysin, and later by Kraus and Clairmont<sup>7</sup> and Neisser and Wechsberg<sup>8</sup> for other bacterial lysins. In the case of megatheriolysin various normal sera exercise a considerable anti-hæmolytic action, both towards the corresponding corpuscles and also towards those of other animals; thus normal human serum protects human corpuscles against the lysin; the sera of the sheep and pig are strongly anti-hæmolytic towards their own corpuscles; donkey's serum has a marked action in protecting the corpuscles of the guinea-pig against the lysin, and this anti-hæmolytic power is increased by heating the serum for half an hour at from 63° to 65° C. No change takes place on heating for the same time at 60° C. Thus in one experiment it was found that a tube containing two cubic centimetres of 5 per cent. suspension of guinea-pigs' corpuscles required 0.05 cubic centimetre of the filtered culture for complete hæmolysis. If, however, 0.2 cubic centimetre of normal donkey's serum was added to the suspension 0.50 cubic centimetre—i.e., ten times as much—of the filtered culture was necessary, and if the donkey's serum had been previously heated to 64° C. for half an hour 0.90 cubic centimetre was required, so that the anti-hæmolytic action of the serum had been almost doubled by heating. The same phenomenon is observed in the case of sheep's serum and

also of horse's serum, though in the latter case it is not so marked.

It is not easy to see any explanation of this increase in the anti-hæmolytic action of normal sera on heating, and it is possible that it is merely a physical effect depending on an alteration of the osmotic conditions, as the temperature of heating is so near the coagulation-point that the sera are quite viscid.

*Immunisation of animals.*—The subcutaneous injection of filtered cultures of the bacillus in guinea-pigs gives rise to a large local swelling with subsequent necrosis, and after several injections the serum of the animal acquires powerful anti-hæmolytic properties; but the guinea-pig is not a convenient animal for the production of an anti-serum, both on account of its small size and the tendency to local necroses. These necroses do not occur in the goat and the injections appear to cause very slight inconvenience in this animal. Two goats were immunised with the filtered cultures, beginning with one cubic centimetre subcutaneously and gradually increasing the doses up to 100 cubic centimetres. 10 days after the last injection the animals were bled and the serum was tested. In both cases it was found to be very strongly anti-hæmolytic. In one case one cubic centimetre of the serum completely neutralised 17 cubic centimetres of a filtered culture of the bacillus, this amount of the particular culture being enough to cause the complete hæmolysis of 1700 cubic centimetres of a 5 per cent. suspension of guinea-pigs' corpuscles in three hours at 37° C. The animal from which this serum was obtained was immunised with cultures of the bacillus obtained from hay infusion, and its serum was found to neutralise the lysins formed by each of the three races of the bacillus used; thus confirming the view that these three bacilli—in spite of slight cultural differences—were all races of the bacillus megatherium. Having obtained a strongly anti-hæmolytic serum, the constitution of the hæmolyisin was investigated by Ehrlich's method of partial neutralisation, and it was found that the results of these determinations when plotted yield "spectra" similar in character to those obtained in the case of diphtheria toxin, and more especially resembling those obtained by Madsen<sup>5</sup> for tetanolyysin.

*Action of the filtered cultures on animals.*—In guinea-pigs, when given subcutaneously, even in doses as large as 20 cubic centimetres, the filtered cultures do not produce death, but give rise to a large swelling with subsequent necrosis. The substance giving rise to this necrosis is destroyed by heating at 60° C. for half an hour, but does not appear to be

Table showing Results of Intravenous Injection of Filtered Cultures of the Bacillus Megatherium in Guinea-pigs.

No. of guinea-pig.	Dose of filtered culture injected intravenously.	Symptoms.	Result.
1	1 c.c. + 9 c.c. saline.	Five hours later, hæmoglobinuria. There were no red blood corpuscles in the urine.	Lived.
2	2 c.c. + 8 c.c. saline.	Five hours later, hæmoglobinuria. There were no red blood corpuscles in the urine.	Lived.
3	5 c.c. + 5 c.c. saline.	One and a half hours later, hæmoglobinuria. Crystals of hæmoglobin and a few blood corpuscles were found.	Lived.
4	8 c.c. + 2 c.c. saline.	Three hours later, hæmoglobinuria. Crystals of hæmoglobin and many blood corpuscles were present.	Lived.
5	10 c.c.	Two hours later, hæmoglobinuria; there were no blood corpuscles. Three and a half hours later, hæmoglobinuria; many blood corpuscles were present.	Died in 12 hours.
6	10 c.c.	Hæmoglobinuria, hæmaturia, and epistaxis.	Died in 10 hours.
7	10 c.c. + 0.5 c.c. anti-serum.	No symptoms.	Lived.
8	10 c.c. + 5 c.c. anti-serum.*	No symptoms.	Lived.

\* In this case the anti-serum was given subcutaneously and 24 hours before the intravenous injection of the filtered culture. The animals used were all approximately 500 grammes in weight.

neutralised, at any rate completely, by the serum of immunised animals.

The action of the filtered cultures when given intravenously in guinea-pigs is seen from the appended table. The results depend naturally upon the strength of the culture, but with the lysin used in these experiments a dose of 10 cubic centimetres intravenously was usually fatal; with smaller doses—from one cubic centimetre to eight cubic centimetres—the animals survived. A few hours after the injection the urine passed was a dark reddish-brown, often of the colour of stout, and gave the oxyhæmoglobin spectrum. If the urine was passed shortly after the injection, most commonly no red blood corpuscles were present, but these generally appeared later, and with large doses were found in the urine passed quite early. The hæmoglobin appears to be excreted mostly in the form of oxyhæmoglobin.

When mixed with a small amount of the anti-serum intravenous injections even of large quantities of the lysin produce no hæmoglobinuria, and if the animals receive a subcutaneous injection of the anti-serum the day before the intravenous injection of the lysin no hæmoglobinuria results, showing that the hæmolysis is brought about by a specific lysin and not by a simple chemical or physical action. In this connexion it is interesting to note that in the rabbit—the corpuscles of which are only very slightly affected by the lysin *in vitro*—large intravenous injections of the lysin produce no hæmoglobinuria.

The fact that a widely distributed organism, which has hitherto been regarded as practically non-pathogenic, is capable of forming products bringing about in susceptible animals such profound blood-changes is of the greatest interest, and although this bacillus may have no causal relation to any pathological condition in man or the lower animals, still the results obtained are suggestive in connexion with the pathology of such diseases as blackwater fever, paroxysmal hæmoglobinuria, and pernicious anæmia.

Harrow.

## MOVEABLE OR FLOATING KIDNEY A CAUSE OF ACUTE AND CHRONIC PAINFUL DYSPEPSIA,

WITH NOTES OF CASES.

BY ALEX. MACGREGOR, M.D. ABERD., M.R.C.P. LOND.,  
PHYSICIAN TO THE NORTH LONDON HOSPITAL FOR CONSUMPTION AND  
DISEASES OF THE CHEST.

MOVEABLE or floating kidney is by no means rare, yet it is frequently overlooked or apparently not suspected. If in the treatment of cases of chronic painful indigestion a systematic examination of the abdomen be made it not infrequently will be found, especially in women, that the cause of the dyspepsia is not in the stomach itself, but that the interference with the functions of that organ is due to the wanderings of a dislocated kidney. Except in those cases where the dislocation interferes with the functions of the kidney itself no symptom points directly to the nephropathosis. The kidney is not readily thought of as being the cause of an acute attack of jaundice with sickness and severe pain in the epigastrium, yet it has been known to give rise to such symptoms, and the first of the cases hereafter described is an example. Malignant disease of the stomach, too, has been suspected and diagnosed in not a few instances, as in Case 2, where further observation and examination proved a dislocated kidney to be the cause of the grave symptoms. The pain in the region of the pylorus, increased by food, the sickness, emaciation, and the icteric tint of the skin make the diagnosis of malignant disease, and especially in a patient aged about 40 years, a very natural one. Dr. Herbert Bramwell of Cheltenham recently published a most interesting case which ended fatally.<sup>1</sup> A post-mortem examination in this case proved the correctness of the diagnosis and added a valuable contribution to our knowledge of the altered condition of parts which gives rise to the symptoms. In Allbutt's System of Medicine<sup>2</sup> this altered condition of parts is fully described. There it is stated that bands of peritoneum produced by the dislocated kidney have been

found to cause dilatation of the stomach by mechanically obstructing the normal passage of the chyme. "Such bands may pass occasionally from the upper part of the duodenum, but they are more commonly attached to the middle or lower part of the descending portion in the position nearly opposite that at which the bile-duct enters. The drag of the peritoneum on the duodenum is probably the commonest cause of the temporary jaundice which often accompanies the gastric crisis and of the dilatation of the gall-bladder." In the light of this Case 1 is clear and so is Case 3, which is an exact parallel to the early stage of Dr. Bramwell's case, but fortunately in my patient a short rest in bed and the wearing of a suitable pad and bandage gave complete relief from the symptoms. In the majority of cases the prominent symptoms are indigestion, pain more or less constant, and almost always increased by food, flatulence, and constipation.

The frequency with which moveable kidney is met in women as compared with men is very striking and puts it beyond doubt that there must be a cause at work in women which rarely or never acts in the male. The cases which I have met with seem to me to prove that the most common and most likely cause is tight-lacing *plus* muscular effort, as, for example, in cycling. One patient whose symptoms suggested malignant disease of the stomach dated the onset of her illness from a 50-mile bicycle ride and another patient of excellent physique began to suffer from the characteristic symptoms immediately after a 12-mile ride over a hilly road against time. In the case of two other female patients falls in the hunting-field were given as the probable cause. One of those two cases is interesting from the fact that for years the patient suffered from indigestion and pain in the right ilio-lumbar region, and by several gynaecologists she had been treated for "something wrong with the ovary and womb," but without benefit. This patient's right kidney lay low down and forward in the lumbar region and could easily be pressed upwards almost to the gall-bladder. The symptoms in this case were always more severe just before, and usually during, the menstrual period. "The catamenial aggravation of the characteristic sensations has been pointed out by Becquet, Lancereaux, Sawyer, and Fourrier."<sup>3</sup> I was able to observe this in Case 1, where with the onset of a menstrual period the kidney became distinctly enlarged and there was a threatening of a return of the gastric crisis with jaundice which accompanied a previous period. In neurotic women the symptoms are often misleading and sensations are felt in parts far removed from the offending kidney. One nervous woman complained of pain in the stomach passing up through the chest to the throat accompanied by distressing "choking sensations and terrible feelings all over the body." Her organs seemed perfectly normal, but the right kidney was freely moveable. Another woman, neurotic and anæmic, complained of occasional loss of voice and choking sensations which she associated with pain in the stomach, and the latter symptom was always increased by food. At first the abdomen was not examined, but as no relief followed the usual medicinal treatment for dyspepsia an examination was made and both kidneys were found to be freely moveable. The thin flaccid abdominal walls made palpation easy, and the kidneys were easily grasped and could be moved over a wide area. An interesting case came under my care while writing these notes. The patient, an unmarried woman, aged 37 years, consulted me on Nov. 20th and gave me a long but clear and intelligent account of years of suffering from indigestion. Two years ago, owing to her inability to take food because of the pain and sickness which it caused, she became terribly emaciated and was sent to a home to undergo the Weir-Mitchell treatment. There she improved immensely, put on weight, and was afterwards able to take a sea voyage. During the voyage, however, the symptoms returned, but they were not so severe. She is now gradually getting back to the condition she was in before undergoing the Weir-Mitchell treatment. She "cannot touch beef or mutton and can take only very small quantities of the simplest food." She was told that she was neurotic (and she knows that she is), but she is "most anxious to be able to eat food like other people." Except for a slight cardiac peculiarity this patient's organs seem perfectly healthy, but the right kidney is dislocated and lies near the upper border of the iliac region and can be pressed up almost to the gall-bladder. Of course, it is impossible

<sup>1</sup> Brit. Med. Jour., Oct. 19th, 1901.

<sup>2</sup> Vol. iv., p. 346.

<sup>3</sup> Allbutt's System of Medicine, vol. iv., p. 343.

now to say that the dislocated kidney was the cause of the painful dyspepsia and the resulting emaciation for which she was treated two years ago, but I am more than inclined to think that that is the true explanation of the case. An equally interesting case is that of a young woman who suffered for years from dyspepsia, flatulence, constipation, and pain in the right side of the abdomen, always increased by food. In January, 1900, she was operated upon for appendicitis and was told that the "appendix was very bad." She consulted me 10 months after the operation and said that she still suffered much pain in the right ilio-lumbar region, that the pain was most severe from an hour to an hour and a half after a meal, and that there were obstinate constipation and distressing flatulence. Aperients and aids to digestion gave only slight and temporary relief and on this account when she consulted me again in January of this year I examined the abdomen and found the right kidney lying low down in the lumbar region.

Although nephroptosis is most frequently met with in thin women who have had children emaciation is not necessary for its production, nor is it uncommon in unmarried women. Several of my patients had more than an average amount of adipose tissue, and five recently under my care were unmarried.

I have only once met with the condition in a man. His right kidney was enlarged, floating, and, I believe, diseased. He gave a history of having been crushed against a wall by a horse. In less than two years I have seen 12 cases in women, but I shall add short notes of only a few of them.

CASE 1.—A married woman, aged 31 years, the mother of two children, was admitted to the North London Hospital for Consumption under my care on Sept. 23rd, 1901. On Oct. 18th, just before the onset of a menstrual period, she had an attack of acute pain in the right side of the abdomen. I saw her two days later and then the abdomen was somewhat distended, there was severe pain with tenderness in the epigastrium and to the right of the middle line. The pain was most acute at a point a little above and to the right of the umbilicus. The liver dulness was slightly increased and the rounded end of the distended gall-bladder was palpable, but deep palpation was impossible. On Oct. 28th the acute pain and tenderness were no longer felt and the jaundice was disappearing. Deep palpation was now possible and the right kidney, somewhat enlarged and freely moveable, was found lying well forward in the lumbar region. The patient stated that for six months she had "felt something move or fall in the right side when she turned from one side to the other in bed." At the beginning of the next period there was a return of the same symptoms, but they were much less severe. The kidney again seemed to enlarge somewhat and there was decided tenderness.

CASE 2.—A woman at about the middle period of life, married but having no children, was seen by me in consultation in July, 1900. For some time she had been suffering from pain after food, nausea, and loss of flesh, and there was an icteric tint in the skin—symptoms strongly suggestive of malignant disease of the stomach. Nothing abnormal was to be found in the stomach itself and all the other organs seemed to be perfectly healthy, but the right kidney was dislocated downwards and forwards. She attributed her illness to a trying 50-mile bicycle ride. No malignant disease of the stomach has since developed.

CASE 3.—A woman, aged 32 years, married and the mother of four children, came as an out-patient to the North London Hospital for Consumption on Oct. 8th, 1901. She was very depressed, weak, and emaciated, and there was an icteric tint in the skin. Her history was that she had suffered from painful dyspepsia for several years, but the symptoms were much worse since the birth of her last child 10 months ago, and for nearly two months before her visit to the hospital she had been unable to retain a single meal because of the pain which it caused. The emaciation and flaccid condition of the abdominal walls made palpation of the viscera easy. Nothing abnormal was detected in the stomach, but the right kidney was found to be dislocated: it could be easily grasped and moved over a wide area. No medicinal treatment was given, but she was kept in bed for a fortnight, and during that time there was no sickness, and little or no pain. At the end of the fortnight an L-shaped pad kept in place by a suitable bandage was applied and she was no longer confined to bed. There has been no sickness or pain since and the patient eats well and is rapidly putting on flesh.

CASE 4.—A married woman, aged 48 years, had suffered

more or less for 10 years. She complained of pain in the epigastrium and right hypochondrium and sickness after food, and she stated that the vomiting frequently came on at night. The bowels were alternately relaxed or constipated. Her right kidney was floating.

CASE 5.—A woman, aged 39 years, unmarried, consulted me in November, 1900. She had for years suffered from indigestion, distressing flatulence, constipation, and severe attacks of pain in the neighbourhood of the cardiac end of the stomach. The pain was frequently accompanied by much retching. The usual remedies gave only slight and temporary relief. Her left kidney was moveable and could easily be grasped and rolled between the fingers in bimanual examination. A pad and bandage gave little or no relief, probably because she was more than fairly stout.

CASE 6.—A woman, aged 39 years, married, and having one child, consulted me in February, 1901. She was distinctly neurotic, stout, and of excellent physique. She complained of vertigo, indigestion, and sudden attacks of pain in the stomach and right lumbar region. The appetite was good, the tongue was clean, and the bowels were relaxed. All the organs seemed healthy. As in the other cases, the remedies gave no relief except as regards the vertigo. The pain was first noticed four months previously after cycling up some stiff hills. Pain was felt in the abdomen on turning in bed. Owing to the amount of adipose tissue in the abdominal walls palpation was not easy, but the right kidney was made out to be freely moveable. After wearing a pad and bandage the pain was never so severe, but there was still aching.

It is unnecessary to give further details of individual cases. Those which I have given show, I think, that the symptoms and sensations are so characteristic that when in apparently ordinary cases of dyspepsia medicinal treatment fails, moveable or floating kidney ought to be suspected and examined for.

Unfortunately, the treatment by pad and bandage is not always satisfactory, but in none of my cases have I found it necessary to recommend operation. Yet Dr. Bramwell's case shows that nothing short of operation can under certain circumstances save the life of the patient.

The frequency with which nephroptosis is met in women is, as I have already remarked, striking; and no less striking in my experience is the fact that the right kidney is much more frequently dislocated than the left. In my last 12 cases the right kidney was dislocated in eight, the left in three, and both were dislocated in one patient. The explanation seems to me to lie in the fact that in muscular effort and severe straining the right kidney gets nipped at its upper end between the muscles of the back behind and by the liver and diaphragm in front and above, and is so pressed out of its normal position.

As regards the method of examination, either for the right or the left kidney, I find it best to stand at the patient's right side. The fingers of the left hand are placed in the lumbar region behind and pressed forwards, while the right hand pressing backwards is moved upwards and downwards over the side of the abdomen in front. In this way a dislocated kidney is more or less (according to the condition of the abdominal walls) readily detected and often slips from between the fingers with a distinct jerk.

Queen-street, W.

## CHRONIC EPISTAXIS (? VICARIOUS MENSTRUATION); CAUTERISATION OF THE NOSE, FOLLOWED BY GREAT GENERAL AND LOCAL IMPROVEMENT.

By BERNARD E. MYERS, M.D. EDIN., L.R.C.P. LOND.

THE following case has, I think, certain points of interest.

A young woman, aged 23 years, came to see me in June, 1901, on account of anæmia. She looked very ill and had an extremely anxious expression, whilst her cheeks, lips, and conjunctivæ were markedly pale. The patient complained of being in a constant state of hebetude and breathless on the least exertion, of pain and palpitation in the præcordial region and swelling of the ankles in the morning, also of stomach troubles, &c. She had suffered occasionally from rheumatism. Her family history was as

follows. Her father had had rheumatic fever and suffered for many years from epistaxis. One young sister, aged nine years, had also suffered from epistaxis since she was four years old. When my patient was five years of age she first bled from her nose, and this bleeding continued on and off till August of this year. The bleeding started without any warning, and until she was 13 years old it often occurred from seven to nine times daily, and she lost, according to her statement, at least a teaspoonful each time. The bleeding tended to be worse in summer. There were very few days during which she did not bleed once at any rate. She said that she was always ailing and had a perpetual frontal headache and a shocking memory. When she was 13 years old she first menstruated and then saw nothing again for five years. During this time she became generally worse and was very depressed in spirits. At 18 years of age she felt at what she called her periods great pain in the pelvic region and had a white discharge, but lost no blood per vaginam. This condition always lasted for one day and came on every three or four months until recently. From the age of 13 years she had also suffered (besides the ordinary daily small losses) from larger losses from the nose about every four weeks, amounting to one-half or two-thirds of a pint during the two days on which it lasted. This larger loss always occurred when she had the pelvic pains mentioned above, so that probably one may look upon this periodic bleeding as vicarious menstruation, though the pelvic pains did not occur every month. After all these larger hæmorrhages she fainted and was practically moribund for some hours. At the age of 17 years she was treated in a hospital for hæmoptysis and hæmatemesis, but I understand from her account that the amount of blood lost from the lungs or the stomach was never excessive.

In June, 1901, when I first saw her, she was suffering severely from secondary anæmia. There were also old quiescent mischief of the right apex of the lung and gastric ulcer. The usual signs and symptoms of anæmia were rather excessively marked, and I noted that on very gently touching the right or left side of the septum nasi in the usual area with cotton-wool on a probe there was an immediate oozing of blood. I gave her five grains of Bland's pill and 1/16th of a grain each of arsenic and strychnine thrice daily after meals; also a solution for douching the nose and an astringent dusting powder for the same purpose. She became a little better and there was a longer time between the bleedings, occasionally two weeks; but now when the epistaxis did start it was worse than ever, and on several occasions I had to put plugs of lint soaked in tincture of hamamelis into each nostril. Her appearance after these attacks was very ghastly and vision completely failed her for half an hour afterwards.

Early in August, after having exerted herself a little more than usual in attending on a sick friend, she suffered from the worst hæmorrhage that she had ever experienced, and for two days I was extremely anxious about her, and so I determined to treat both sides of the nose with the galvanocautery. There was a certain element of danger in doing this on account of the possibility of bringing on hæmoptysis or hæmatemesis again: still, it was quite worth chancing, as I was rather afraid of the possible effects of another severe bleeding suddenly coming on.

Since cauterisation was performed her improvement has been very great indeed, and though it is 18 weeks since it was done she has not had epistaxis once (in the ordinary way she would have had over 50 attacks in this period), whilst her complexion has a healthy rosy tint and her lips and conjunctivæ are for the first time of normal colour. She eats well, sleeps well, and can do her daily duties without fatigue—a condition quite new to her. The mucous membrane of her nose, which was formerly turgid with blood, has now almost the normal hue. She has had no trouble with her lungs, but a slight hæmatemesis occurred three weeks after cauterisation. Her heart beats more vigorously than hitherto. Since the epistaxis has stopped she has menstruated four times, at intervals of four weeks. Her periods last for three days, the pelvic pain is much less than formerly, and for the first time since she was 13 years old she has lost blood per vaginam at her menstrual periods. The amount of blood lost is increasing each period, though it is still only four ounces or so for the whole menstruation. Perhaps it is too soon yet to judge whether the present satisfactory state of things will last, but it has had a fair test, and at present I have seen no bad results whatever, and I would be inclined to cauterise again in a similar case to this one.

West Hampstead, N.W.

## A CASE ILLUSTRATING THE RELIEF OF SEVERE HEADACHE BY CORRECTION OF REFRACTION ERROR,

WITH REMARKS ALSO ON THE EFFECT OF CYCLING IN SOME CASES.

By SIMEON SNELL, F.R.C.S. EDIN.,

OPHTHALMIC SURGEON, ROYAL INFIRMARY, SHEFFIELD, AND PROFESSOR OF OPHTHALMOLOGY, UNIVERSITY COLLEGE, SHEFFIELD.

ON Oct. 17th, 1901, a man, aged 32 years, consulted me in consequence of long-continued and severe headaches. He gave the following account of himself. He had been a missionary in the East. The headaches commenced about February, 1899. He had had considerable stress of work at that time and he felt generally run down. The headaches began on the left side, to which also they were chiefly confined. They commenced sometimes about the eye, and at other times about the teeth. At first there was a sort of hot feeling which, after a time, gave place to more acute pain, apparently like neuralgia. If pain was not present there was a constant numb feeling all along the left side and the top of the head reaching to the occipital region. He described the feeling, which was constantly with him, as if one side of the head was boiling hot or in flames, and it took all the energy out of him. He consulted a medical man who tried his sight and declared that it was above normal. He designated the complaint "hemicrania" and put on the certificate "cause undiscovered." At this time, also, as it was suggested that his teeth were responsible for the headaches, two were extracted from the left upper jaw. As a result of the examination by the medical man just referred to he was invalided to another part of the country for six months, but during that period he was able to do some amount of work. The change and comparative rest were beneficial. He resumed regular work in the autumn of 1899, and continued it until the beginning of the present year (1901) when headaches of the same character as at the beginning of 1899 returned. He was treated by another medical man who regarded the headaches as rheumatic, but without avail. He was then sent back to England in February last, landing in this country in the middle of April. On his arrival he was brought before the medical board and ordered six months' rest. At the expiration of that time he presented himself before the board for re-examination. The headaches still remained, though somewhat modified in severity. The principal medical officer could not say what the cause was, and therefore advised him to consult an oculist. He then came to me.

At the time of his visit I found that he was still suffering considerably from headache, though apparently not so badly as before. The numb feeling was constant and there were exacerbations of more acute pain. He thought that exertion rendered the headache worse, but he was unable to use his eyes with comfort and he himself considered that they had a good deal to do with his suffering. On examination I found vision in each eye was  $\frac{5}{6}$  and that spherical + glasses rendered it worse. Both eyes were placed under the action of homatropine and cocaine and then in each eye vision =  $\frac{5}{6}$ , or with + 5D. cyl.  $\frac{5}{6}$ , axis horizontal. The muscle balance appeared to be normal. He was accordingly ordered these cylinders for general use. A week later he returned to me and reported himself as being greatly relieved, better, indeed, than he had been for a very considerable time. Whilst wearing the glasses the numb feeling in the head had disappeared, but it came back again if he left them off. He mentioned, however, an interesting fact that two days previously, after a bicycle ride, the pain in the head had returned and he was anxious to know whether cycling would be likely to be injurious. He had cycled a good deal when in the East, and he thought that it tended to aggravate the pains in his head. I explained to him the way in which I thought that it might do this. He was, I ascertained, in the habit of leaning forward and, therefore, on looking straight in front of him he would necessarily be using and straining the elevator muscles. This would cause discomfort just in the same

way that "Academy" or "sightseers" headache is occasioned by looking at pictures hung above the line or by the more prolonged use of the elevators nystagmus in miners is produced. On calling on me later he expressed himself as so considerably relieved that he was anxious to return to work and therefore desired my permission to accept a curacy in the south of England. He was able to read with much greater comfort than had been the case for a considerable time. He informed me also that he was satisfied as to the correctness of what I had told him about the strain caused to the elevator muscles in cycling, because, as a test, he had placed and kept his eyes in the position I had indicated and it had soon occasioned similar discomfort. I saw the patient again on Nov. 22nd. He expressed himself as better and more fit for full work than he had been at any time since he began his labours in the East. He was able to read with comfort for long periods, and felt confident of being able to fulfil his clerical duties which he was to enter upon the next day.

Instances of headache occasioned by errors of refraction are very frequent and are met with daily in one's practice. The relation between ocular conditions and headache has become well recognised by the profession, and the number of cases coming before one's notice in which the causal relation between the two has in the first instance been suggested by the family medical practitioner are always on the increase. There would, therefore, be nothing in an ordinary case worthy of bringing under notice. I merely mention this instance because the headache was severe and long-continued and the relief occasioned by correcting the ocular defect was speedy and well-marked. It may be stated that the error of refraction met with in these cases is often of a low degree; especially is this so with regard to astigmatism. In the present instance the astigmatism was only half a dioptre, but there was the additional factor that the axis of astigmatism was contrary to the rule—that is to say, the axis of the + cylinder was required horizontal instead of vertical. In the case related the muscle balance was normal, but in all such instances it is desirable to examine the muscles, for it has often happened in my experience that they are at fault, and the use of prisms, alone or in combination with the correcting glasses, has been of distinct benefit.

Another point worthy of remark is the relation of cycling to headache or discomfort in the eyes. If the cyclist sits upright and does not lean forward on the handle-bars he will look straight in front of him and the direction of his gaze will be rather below than above the horizontal line. My observations in miners, compositors, platelayers, and many other occupations show that prolonged use of the elevators tends to produce nystagmus or ocular discomfort. Especially in miners, nystagmus is the outcome of this continued strain upon the elevators. The same is met with in other trades, but there are many instances in which only discomfort and aching of the eyes are complained of. A like remark applies to visitors to the Academy or other picture galleries in whom in consequence of the eyes being directed above the horizontal line discomfort is occasioned, and thereby many sightseers suffer from what has been described as "Academy" or "sightseers" headache. I am satisfied that this is, in many instances, the true explanation of this form of headache. Turn the eyes below the horizontal line and even prolonged effort does not produce discomfort; on the other hand, turn the gaze above the horizontal line and discomfort results. I have observed instances of this in cyclists who have been in the habit of stooping and leaning on the handle-bars. It follows, as they have to look forward, that their eyes must be directed above the horizontal line. This remark, of course, is much less true in many cases than in others. In the one I have related a return of the headache resulted from a rather long cycle ride. As already stated, on questioning the patient, it was found that he was in the habit of stooping and leaning on the handle-bars and looking in the direction I have suggested as occasioning the weariness of the elevators and consequent headache. The accuracy of this observation he was able to endorse from tests which he made himself. I mention this particularly because I think that it is an explanation of the headache or eyache sometimes complained of by cyclists, and the cause once recognised admits of easy remedy.

Sheffield.

At a Chapter-General of the Order of the Hospital of St. John of Jerusalem held on Nov. 26th Mr. J. M. Carvell, M.R.C.S. Eng., L.S.A., was selected for enrolment as an Honorary Associate.

## Clinical Notes:

### MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

#### NOTES ON SOME SKIN LESIONS.

BY EDWARD C. B. IBOTSON, L.S.A.

*Epidemic acne varioliformis.*—A healthy man, aged 20 years, consulted me on account of an extensive eruption which had come out on his skin in two days' time. There was no history of taking any drug and he had no syphilis past or present. He amused himself with photography and took his own portrait for me, showing, though imperfectly, the skin lesion. He informed me that he had noticed an exactly similar eruption to his own on three or four other young men in the works at which he was employed. The lesion commenced as a flat red papule and the size of the papules varied from one-third to a quarter of an inch in diameter. On the papule a minute vesicle next appeared containing clear fluid. I regret not having obtained some of this fluid for bacteriological examination. When the vesicle burst it left a sharply defined small pit behind. As regards the distribution of the lesions they were most copious on the forehead, next on the cheeks, next on the chest, and finally there were a very few papules on the arms and legs. I did not notice vesicles on the arms or legs. The man felt somewhat languid but was otherwise in good health. I prescribed five-minim doses of Fowler's solution after food, one-tenth of a grain of calcium sulphide in a pill thrice daily, and locally Hutchinson's paint—namely, equal parts of liquor carbonis detergens, rectified spirit, and liquor plumbi subacetatis. Under this treatment there has been marked and steady improvement.

Dr. Sabouraud has recently found the lesions of acne varioliformis to contain the golden staphylococcus (*staphylococcus pyogenes aureus*). Is it not possible that, this organism being somehow present on a towel, these young men may have inoculated themselves with the germ by using the same towel to wipe their faces and so rubbed in the germs and thus produced this small epidemic? Had he been a hospital patient I should undoubtedly have restricted myself to local treatment only, as I think it doubtful whether the internal treatment should be regarded as the beneficial agent in his case. Morris praises iron and cod-liver oil and says that the duration of these cases may be long. It is noteworthy that this case made rapid improvement; also that the age is unusual, as most of these cases have occurred after 40 years of age. Theoretically one would suppose that the pyococci are allowed to develop owing to defective phagocytosis, and hence also the boils and carbuncles that occur in association with albuminuria and diabetes. Iron undoubtedly will improve the percentages of hæmoglobin and red cells, but I do not know whether the leucocytes have ever been seen to increase in number with iron. Arsenic is given frequently in leucocythæmia, presumably to diminish the number of leucocytes, and therefore theoretically one would have imagined arsenic to be a friend to pyococcal infection, whereas it has proved beneficial in this case, and, moreover, it has been shown by Mr. Hutchinson to be a specific in pemphigus.

*Non-specific and specific pemphigus neonatorum.*—I have lately seen a bullous eruption in a newly-born infant which appeared to me to be secondary to a pyococcus infection of the conjunctiva. The mother had a yellow discharge throughout pregnancy and a creamy discharge appeared on the child's conjunctiva on the second day after delivery. The pus contained staphylococci. There was no history of gonorrhœa in the father. Bullæ appeared on the chin first, about as large as a threepenny-piece—viz., one-third of an inch in diameter. When these bullæ ruptured a clear yellowish serum escaped and a flat greyish-yellow circular crust remained. The eruption invaded the cheeks, scalp, neck, chest, and hands. One bulla on the chest reached the size of a halfpenny. The legs and feet were not affected. There were none of the signs of syphilis. The case appeared to be one of those described by Crocker as non-syphilitic pemphigus neonatorum. It yielded to the following treatment. For the conjunctivæ a wash of perchloride of mercury (1 in 1000); to the skin a dusting

powder of zinc oleate, boric acid, starch, and thymol, and theunction of weak ammonio-chloride of mercury ointment.

I have had under observation a true syphilitic pemphigus neonatorum—a female child, 20 months old, of foreign parents. The bullæ were numerous, deep-seated, and dark in colour. There was a distinct history of syphilis at an earlier age. The smell was very strong. The interesting point is that the palms and soles were not affected in the least. Treated with mercury and chalk, one grain three times a day, this child has completely recovered and is fat and strong.

Ashchurch-grove, W.

#### CASE OF SPONTANEOUS RUPTURE OF THE BOWEL.

BY T. CARWARDINE, M.S. LOND., F.R.C.S. ENG.

RUPTURE of the intestine from its own muscular action must be a rare event. It occurred, however, in a case of rectal cancer which was under my care in the Bristol Royal Infirmary.

The patient, a man, aged 50 years, was sent to me from Bridgwater in September, 1901, complaining of difficulty and straining in the passage of his motions, which were chiefly of a soft or liquid character. He looked well, and his abdomen was soft and lax. He was found to have an annular carcinomatous stricture of the rectum some two inches from the anus, the lumen of which would just admit the forefinger. It was intended to perform colostomy, and the patient was kept in bed for some days. Preparatory to the operation he was given a colocynth pill and he went to the closet twice the same night. The next morning he was observed to be rather cold and seemed in a good deal of pain. At 11.30 A.M. he "got a fearful spasm," as the nurse expressed it. The abdomen was hard and distended. He was cold, livid, and collapsed, and remained so till the early afternoon, when he died in great pain. At the necropsy the peritoneum was found to be full of soft, liquid feces; and in the sigmoid flexure, some six inches from the stricture, there was a rent about one and a half inches long, having a longitudinal direction and situated opposite to the mesenteric attachment. Its edges were clean-cut and there was no sign of ulceration or inflammation in the bowel around. The intestine had evidently ruptured as a result of muscular action, although there was no complete obstruction. The appearances were strikingly different from those seen when an ulcer, resulting from obstruction, perforates.

*Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.*—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

#### ST. GEORGE'S HOSPITAL.

A CASE OF ACUTE PARALYSIS CLOSELY RESEMBLING  
LANDRY'S PARALYSIS (SO-CALLED); RECOVERY.

(Under the care of Dr. ISAMBARD OWEN.)

It can hardly be doubted that under the name of Landry's paralysis many cases have been reported which are not of the same essential nature as those originally described by Landry. Although we know nothing definite of the etiology of these cases, yet there can be but little doubt that they are toxic in origin. In the following case there is one point mentioned in the account of the condition on admission to hospital which may perhaps suggest the origin of the disease. It is stated that the gums were swollen and inflamed and that pus exuded from their margins. It has recently been suggested that several obscure diseases are due to the absorption of toxins from suppuration in the mouth, and it is at least possible that in this case also the suppuration around the teeth may have had something to do with the

origin of the disease. For the notes of the case we are indebted to Dr. T. R. C. Whipham, medical registrar.

On Jan. 19th, 1901, a bricklayer, age 24 years, was admitted into St. George's Hospital under the care of Dr. Isambard Owen with a history of having been seized about eight weeks previously with pain in the head and sickness one morning after breakfast. No further symptoms developed till nine days before admission when he noticed "tingling pains" and loss of strength in the arms. On the following day he experienced pains in the calves of the legs on going up and down stairs. On Jan. 12th he vomited soon after drinking a glass of beer and gave up work owing to increasing weakness and difficulty in walking, the latter symptom being due to loss of power in the knees and not to any alteration in the gait. Prior to the onset of his illness the patient had been employed in building a tall chimney in which for the purpose of obtaining light several oil lamps were kept constantly burning, and from these very offensive fumes emanated. Subsequently to relinquishing work the general weakness became more marked, and on the 16th he was unable to walk, though he could maintain an erect position without support. At this time he was suffering from very severe headache in the frontal and occipital regions, especially at night and in the early morning, and he stated that everything which he ate tasted like mutton fat, that his mouth was "stiff" and swallowing difficult, and that water used for the purpose of washing caused a sensation of "pins and needles" down his back. He was taken to the hospital in a cab on the 19th, being then unable to stand. He had had no shooting pains, loss of sensation, or impairment of vision, and he denied having taken any drugs just previously to the onset of his symptoms. The amount of alcohol which he had consumed had been strictly moderate, being limited usually to one pint of beer a day, which was of no particular kind. No trace of arsenic was found in the urine, and nothing in the history of the patient suggested poisoning by that metal. Syphilis was denied, and there were no signs or history pointing to that disease. The bowels had acted regularly and his appetite was fair. Both parents died from cancer; otherwise the family history was good and the patient himself had had no previous illness of any importance.

The patient was a fair-complexioned, well-built man. There was no particular tenderness in the head. The teeth were in a very carious state and the gums were swollen and inflamed and exuding from their margins pus which yielded a short streptococcus on cultivation. The tongue could not be protruded far and was dirty and pushed slightly to the left side, the fauces were congested, and a copious secretion of very viscid mucus was continually being ejected from the mouth, but did not dribble away. There was slight, though distinct, paralysis of the left side of the face. In the upper extremities there was slight general wasting of the muscles from the hands to the deltoid and scapular regions, with considerable loss of power, especially in the right. When on his back the patient was unable to move either arm as a whole from off the bed. The legs when extended were almost powerless, though on passive flexion of the thighs the legs could be flexed and extended at the knee with some little force. The muscles were flabby, but were not markedly wasted. The muscles of the trunk were weak, the patient being unable to sit up in bed unless the legs were allowed to hang over the edge. There was no reaction of degeneration. The spinal column showed no abnormality and all the joints moved freely. The eyes and ocular muscles were normal in every respect, and there were no ophthalmoscopic changes. There was no impairment in any of the special senses beyond a slight "thickness" in the speech due to the facial paralysis and an oily taste with the food. Sensation was perfect everywhere to tactile, painful, and thermal impressions. The reflexes, both superficial and deep, were absent with the exception of the upper abdominal which was present to a slight degree. There were no cutaneous trophic changes and the sphincters were normal. The viscera were healthy and the urine was free from albumin. The temperature was normal.

For the first few days after admission the condition of the patient became worse. There was a further loss of power in the left arm with a "tightness" across the chest and aching in the hands. The secretion of saliva was increased and coryza appeared in the eyes. He vomited on several occasions and experienced slight difficulty in swallowing his food though there was no regurgitation through the nose. The facial paralysis became more marked and severe

shooting pains radiated from the occiput to the forehead. Tingling pains occurred in the legs when they were washed, and some paralysis of the diaphragm was observed. At the end of a week the patient was brighter in himself though the power in the lower extremities was still further decreased, and after a transient improvement in the face the paralysis again became more marked and movement in the right facial muscles was impaired. The headache and pain, however, had disappeared and the secretion of saliva was less. There was no coryza, bad taste in the mouth, or difficulty in swallowing. By the 30th the power in all four extremities was even more diminished. There were tenderness in the calves and some loss of tactile sensation, while the occipital pains had returned with sensations of giddiness. Sharp aching pains were also experienced in the legs and shoulders, which were relieved by the position of the limbs being changed. The paralysis of the diaphragm, however, had disappeared. He vomited on this day for the last time during his illness. Slight epistaxis followed, and on Feb. 2nd the patient complained of stiffness in the mouth and jaws, causing the food to accumulate in the cheeks; there was, however, no difficulty in swallowing or perversion of taste. The "stiffness" was apparently due to the facial paralysis, which by this time was marked on the right side, though scarcely so pronounced as on the left. From this point the patient began to improve, and on the following day there was more power in the arms and legs, the headache and giddiness were less pronounced, and there was no salivation to speak of. The facial paralysis on the right side soon disappeared and the extremities gradually regained their strength, the power in the arms returning before that in the legs. The return of power in the arms was preceded by a sensation of tingling and cramp similar, the patient stated, to the feelings experienced with the loss of strength at the beginning of his illness. The trunk muscles became more powerful, and on the 6th the sensation was noted as "perfect." The upper abdominal reflex, however, was the only one present. Some little pain at this time was caused by weakness of the left peronei muscles and dropping of the left foot, a sign which was present to a slighter degree in the other leg. No reaction of degeneration was observed. By the 26th the arms had regained their full strength, though numbness was complained of in the hands, and the foot-drop had disappeared. The abdominal, scrotal, and plantar reflexes were all present, but the knee-jerks were in abeyance. On March 1st the patient could walk without a stick and the face was practically devoid of any paralysis. The electrical reactions were tested for the last time on the 9th when it was found that although the arm muscles reacted well to faradism those in the legs scarcely did so at all. The reaction of degeneration, however, was not present with the exception of a small tract in the left peroneal region, in which K.C.C. was less than A.C.C. The patient went for a time to the convalescent hospital at Wimbledon, and was finally discharged on the 20th strong and well, though even by that time there was not the slightest sign of either knee-jerk. The bladder and rectum throughout were normal and there was no rise of temperature. No active medicinal treatment was employed during the first month, but subsequently the patient was ordered massage and a bitter tonic containing strychnine.

*Remarks by Dr. WHIPHAM.*—"Landry's paralysis" is a rare disease, even if it be considered to include the various conditions that have been described under that head. It is advisable, however, to restrict the term "Landry's paralysis" to cases resembling that described by Landry himself, in which the chief symptoms consisted of initial subjective sensory changes followed by a rapid centripetal paralysis involving successively the legs, arms, and trunk, with perhaps a late affection of the muscles of the face, the cause being either of central origin, inasmuch as the electrical reactions were unaltered (no recognisable change, however, was found in the spinal cord after death) or due to some toxic condition of the blood.

The case detailed above conforms in many respects with Landry's classical description. The premonitory symptoms, if such they may be called, were slight and consisted merely of an attack of headache and vomiting some two months prior to the acute onset, which began with a tingling sensation and loss of power, in the arms, however, at first, and not in the lower extremities. On this point the patient was very definite, asserting that he first experienced difficulty in raising his arms from one rung to another while ascending

a ladder. The legs, it may be noted, were distinctly involved by the following day, and at the time of admission the muscles of the trunk and face were also implicated. With regard to the subjective sensations a curious point was observed during the stage of recovery, sensations being then experienced in the arms similar to those which occurred with the loss of power. Objective sensation, which was carefully tested, was found to be unimpaired with the exception of a transient diminution in acuteness 20 days after the onset of the symptoms and some numbness in the hands during convalescence. As in about half the cases of typical Landry's paralysis the muscles supplied by the cranial motor nerves were implicated. With regard to the nutrition of the muscles the wasting was at the most but slight, though the muscles themselves were flabby. The electrical reactions were tested on five separate occasions, and it was not until a few days before the patient left for the convalescent hospital that loss of reaction to the interrupted current was observed. This occurred in both legs, though only in one small tract was there any true reaction of degeneration.

The etiology of the case is obscure. There was no history of alcoholic excess or of exposure, and no acute illness preceded its development; moreover, there was no reason to suppose that the patient had suffered from syphilis. One is therefore constrained to believe that it must have been due to some indefinite toxic condition arising perhaps from the unsavoury surroundings in which he had worked, as the patient himself all along imagined. To Dr. Isambard Owen my thanks are due for permission to publish the notes of this interesting case.

## Medical Societies.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

#### *Modern Methods of Vaccination and their Scientific Basis.*

A MEETING of this society was held on Dec. 10th. Dr. SYDNEY RINGER, F.R.S., in the absence of the President, being in the chair.

Dr. S. MONCKTON COPEMAN read a paper on *Modern Methods of Vaccination and their Scientific Basis*. In dealing with the subject he began by giving a short history of the introduction of vaccination and of the various Acts of Parliament which had come into force. He said that the occurrence of certain fatal cases of erysipelas following on vaccination in the practice of the public vaccinator at Norwich had, when he was quite a boy, made a great impression on him and the remembrance of the unfortunate event caused him to turn his attention to the possibility of avoiding the accidental transference of erysipelas and other diseases from one child to another by the substitution of serum preparations of animal lymph for the arm-to-arm method. There was a common belief that calf lymph produced "worse arms" than the method of arm-to-arm vaccination, and culture plates inoculated from calf lymph showed a greater number of colonies of micro-organisms than when inoculated from lymph taken from the human arm. This, he had no doubt, was due to the greater difficulty in cleansing the skin of the calf as compared with that of a child. The opacity which occurred in stored lymph was due to the increase in the number of bacteria in the tube. He had been able to obtain inhibition of the growth of these organisms by mixing the lymph with 50 per cent. of pure glycerine in water, and further, he had been able to show by a series of plate cultivations that the number of bacteria steadily diminished, so that at the end of one month after the admixture no organisms were present on the culture medium. Not only did this method kill off all the usual contamination bacteria but it would also destroy those of tubercle and erysipelas, when these were added experimentally, in comparatively large quantities. Dr. Copeman then dealt with the preparation of the lymph under the following heads. 1. *Vaccination of the calf*.—Suitable animals had to be selected, from three to six months old; they were placed in the quarantine stable for a week, their general health was ascertained, and they were weighed and their temperatures were noted. The lower part of the abdomen was shaved, and after cleansing was inoculated with glycerinated calf lymph by numerous parallel linear incisions. 2. *Collection*

of the vaccine material.—This was taken 120 hours after inoculation. The vesicles and their contents were collected with a sterilised Volkmann's spoon, and in this way the vesicular pulp was removed without admixture with blood. The animal was then slaughtered and was examined by a veterinary surgeon and the lymph was not used until the animal in question had been certified to have been healthy. 3. *Glycerination of the vaccine material.*—The lymph pulp was triturated and mixed with six times its weight of a sterilised mixture of 50 per cent. pure glycerine in distilled water. 4. *Storage of emulsion.*—The emulsion was then placed in small test-tubes and put into an ice-chest, and week by week agar-agar plates were established from the emulsion with the result that the number of colonies was shown to diminish successively. At the end of a month the plate rarely showed any colonies. 5. *Use of the lymph at the animal vaccine establishment prior to distribution.*—Samples of the lymph were taken and children were vaccinated. The results of these vaccinations were recorded, and from the number and size of the vesicles an estimate was made as to the potency of the lymph. 6. *Transference of the glycerinated lymph to capillary tubes for distribution.*—The lymph was transferred to capillary tubes and sealed and stored in ice-chests ready for distribution. 7. *Recording the results of vaccinations by public vaccinators.*—Each public vaccinator had to record the number of the tube used, the number of persons vaccinated, the number of scarifications made, and the number of vesicles obtained. The success attending the use of this lymph in the first year showed a case success of 93 per cent. and an insertion success of 83 per cent., and at the present time it was no unusual experience for returns to show complete case and insertion successes. Dr. Copeman then dealt with the regulation as to the mode of vaccination, with the question as to what constituted efficient vaccination, and with the after-treatment of the arm. He said that he had removed the glycerine from the lymph in order that the lymph might dry more rapidly on the arm, but he did not think that the results were worth the trouble involved in the preparation of such lymph. Deaths directly attributed to vaccination in the year 1893 amounted to 59, rather more than one a week, whilst in the year 1899 only 25 deaths were attributed to vaccination. He then dealt with the relation of vaccinia to small-pox and stated his belief that the former was an attenuated form of the latter, and in support of this statement he quoted the following experiments. He said that it was well known that a calf could seldom be inoculated directly from a case of even confluent small-pox in the human subject, but that if in the first place a monkey were inoculated with lymph from such a case good vesicles developed. If lymph was taken from these vesicles and a calf was inoculated poor vesicles were produced; if a second calf was then inoculated from the first a good crop of vesicles was produced; and then if a child was inoculated with lymph from this calf a typical vaccinia was produced. A second series of experiments in which the lymph from a case of confluent small-pox was passed through two monkeys in succession and then through two calves before the child was vaccinated gave similar results to the experiments above described. Such evidence seemed strongly to support the view that vaccinia was an attenuated form of small-pox. Numerous lantern slides were shown in illustration of the paper.

Dr. LEONARD C. T. DOBSON said that in his experience small calves with thin skin and white hair gave as a rule the best results when vaccinated, but that the results varied very greatly according to the condition of the animal. In some cases when good vesicles had formed in four days, by the fifth they would have dried up and only scabs would remain. Lymph might become inert from various causes; if the glycerine were acid it would rapidly make the lymph inert; heat and light had the same result. There was unfortunately no test for the efficiency of the lymph except its result on the calf and on the child and lymph which produced good results in the calf might be inert in the human subject. He stated that it was possible to produce good vesiculation in the same individual with lymph obtained from different sources, and he said that he himself after having been successfully vaccinated with lymph from the Government laboratories shortly afterwards accidentally inoculated his finger with lymph from another source and a good vesicle resulted.

The discussion was adjourned.

## MEDICAL SOCIETY OF LONDON.

### *The Physical Disabilities for Tropical Life.—The Remote Effects of Tropical Life on Europeans.*

A MEETING of this society was held on Dec. 8th, Dr. W. H. ALLCHIN, the President, being in the chair.

The PRESIDENT referred to the loss which the society had sustained in the death of Sir William Mac Cormac, a former president of the society.

Surgeon-Lieutenant-Colonel ALEXANDER CROMBIE read a paper on the Measure of Physical Fitness for Life in the Tropics. He said that the facility with which the human organism was capable of adapting itself to altered conditions made it possible to maintain a high average of health and efficiency in the tropics for a time, and apart from the diseases which were prevalent in, but not essential to, these regions, such as malaria, dysentery, and cholera, climate, as climate, took a small place among the causes of increased sickness and mortality in hot climates. In the course of time, however, a perceptible deterioration of health began to show itself, especially in those who from defects of constitution or health were least fitted to adapt themselves to the altered physiological processes imposed by high temperatures. These modifications of physiological processes consisted in a lessened demand for thermogenesis and an increased demand for thermolysis, in order that the mean temperature of the body might be kept within physiological limits. The evidences of diminished thermogenesis were to be found in the exhalation of carbonic acid and watery vapour from the lungs and in the secretion of waste nitrogenous products by the kidneys. The amount of carbonic acid given off by the lungs was reduced in the tropics by about 20 per cent., that of watery vapour by about 5 per cent. The demand made upon the respiratory function was therefore lowered, the respirations were fewer in number, and the vascularity of the lungs was reduced by about 12 fluid ounces of blood, while their capacity was increased by about 30 cubic inches. In very high temperatures of 95° F. and over the respiratory exchange was, on the other hand, increased. The effect on health of the lessened demand on the respiratory function in ordinary tropical temperatures was a diminution in the frequency and severity of inflammatory diseases of the chest. People with weak lungs, therefore, did well in such climates. This applied, however, only to equable and moist climates, such as those of islands and near the sea. In inland regions where the extremes of temperature were great inflammatory diseases of the lungs, and especially pneumonia, were frequent and fatal, especially in those who were debilitated by disease. The evidences of lessened metabolism in hot climates found in the urine were low specific gravity, and the smaller quantity of urea, &c., excreted. Kidney disease was less frequent in Europeans, and albuminuria advanced more slowly to secondary changes and uremia. Albuminuria was, however, very common in natives over 40 years of age. As a result of the lowered metabolism of the nitrogenous elements of tissue and food, gout in its acute manifestations was rare, even when the hereditary tendency was strong, but in old residents who lived well the irregular forms of gout were common, especially those of eczema, acid dyspepsia, and congestive derangements of the liver, and high blood tension and headaches in younger men. Acute rheumatism was seldom met with among Europeans in the tropics. In India it occurred chiefly in the dry hot central regions, on the wet west coast, and especially in the hills. A tendency to rheumatic fever was therefore no bar to residence in tropical climates. Acute, or rather subacute, rheumatic fever was not infrequent among well-to-do natives in Lower Bengal, with all the usual cardiac and other complications. Osteo-arthritis was not of frequent occurrence, but did badly in the tropics. Thermolysis, the reduction of body temperature, was accomplished chiefly by increased activity of the sweat-glands and vascularity of the skin. In dry hot climates this increased perspiration evaporated as fast as it was formed; but not so in humid provinces like that of Lower Bengal. There the skin might feel cold and clammy while the temperature of the body was 104° F. The constant presence of moisture on the skin was favourable to the growth of all vegetable parasites, and its vascularity favoured all inflammatory and exudative skin diseases. Very few Europeans were for long free in such a climate from tinea circinata and prickly heat,

and from the ubiquitous presence of the streptococcus, boils were of great frequency, as were also carbuncles which in diabetics often attained enormous dimensions. Dry scaly eruptions, such as psoriasis, were, on the other hand, of great rarity, and might with advantage be sent to a moist tropical climate for treatment. When the temperature of the air rose to or above 95° F., and especially if it was at the same time saturated with moisture, great distress was felt by Europeans and natives alike. It was difficult to understand how the temperature of the body was maintained within physiological limits when the temperature of the atmosphere was many degrees above that of the body, so that there could be no radiation from the surface, and when the humidity was so great as to reduce evaporation to a minimum, and at the same time the unavoidable thermogenesis of tissue and food changes, which were alone capable of raising the temperature 10° or 15°, were necessarily going on. Obesity caused great suffering in ordinary conditions of tropical life on account of the disproportion between the possibilities of thermogenesis in a bulky man and the surface available for the cooling processes. Neurotics, whether the nerve weakness was hereditary or acquired, were also bad subjects for tropical life. There were two departments of Government service in India in which these results were particularly manifested—the Civil Service proper and the Forest Department. It must be clear that to enable a man to re-invigorate an exhausted nervous system, as well as to repair the dilapidations caused by disease, it was above all things necessary that he should have a faultless digestion and stable powers of absorbing nourishment. The man subject to dyspepsia, to "bilious" attacks, and to diarrhoea, either during the hot summer months or from chills at other seasons, should stay at home. If he was at the same time neurotic, as was often the case, he would, if he went to the tropics, sooner or later furnish an example of the very unmanageable association of neurasthenia with dilated stomach which was so frequent in emaciated Anglo-Indians. The great tendency to dilatation of the stomach in the tropics was probably to some extent determined by the habit of imbibing large quantities of fluid during meals. A perfect digestion was also necessary as a protection against microbic diseases which affected the intestinal canal, such as dysentery and cholera, and possibly typhoid fever. The question of phthisis was an important one. It might be laid down for practical guidance that, no matter how strong the hereditary predisposition, a man who landed in such a climate as that of Lower Bengal free from tubercle was little likely to become infected while residing there, but once the disease had started its progress was remarkably rapid. Syphilis could be treated just as successfully in the tropics as at home in its earlier manifestations, but the same debilitating causes which make the treatment of phthisis difficult in the tropics were all opposed to the satisfactory treatment of its later stages. Diabetes, like albuminuria, ran a slower and milder course in the tropics than in temperate climates, especially in patients after 40 years of age. This was especially true of natives, with whom it was very common in the classes corresponding to those who suffered from gout in this country—i.e., in those who lived well, who were of sedentary occupation, and who were engaged in mental labour. Diabetes was the gout of the native judicial department. After all the early attempts to cure diabetes by diet and drugs had failed, a patient who was the subject of a moderate seizure would, if he went to the tropics, probably do just as well as, if not better than, he would if he stayed at home.

Dr. JOHN ANDERSON, C.I.E., read a paper on the Remote Effects of Tropical Life on Europeans. He said that many diseases which had been attributed to heat were in reality due to defects in personal hygiene and habits of life, or an over-stimulating diet, or an excess of alcohol and tobacco. Moderation in such matters was necessary for the maintenance of health in warm climates. The physiological changes induced by heat were the raising of the body temperature nearly half a degree, the slowing of respiration, a slowing of the pulse-rate, and diminished secretion of urine. The nervous system was depressed, digestion was slowed, and nutrition was less active. The diseases that owed their origin directly to malaria were met with long after the sufferer had returned to Europe. These deferred manifestations of malaria were often of a very irregular type and symptoms frequently yielded surprisingly to treatment which, if regarded only from a clinical

standpoint and without a knowledge of the antecedents and medical history of the patients, might lead to an unduly grave diagnosis and cause needless anxiety. Of malarial neuralgias the most common were facial and hemicranial, brow ache, and intermittent headache, but sciatica, intercostal and abdominal pain, burning of the feet, and acute tenderness of the skin were often attributed to the same cause. Locomotor ataxy was seldom or never met with in the natives of India. Europeans, however, did so suffer, and since natives suffered from syphilis their practical immunity from locomotor ataxy suggested the doubt as to the correctness of the theory of the necessarily syphilitic origin of the disease. Serious conditions of the nervous system sometimes resulted from sunstroke; epilepsy, blindness, deafness, and dementia might occur. Affections of the motor nerves were less common. Apyrexial cachexia occurred and was marked by a progressive anæmia so severe that it closely resembled pernicious anæmia. The blood in these cases was diminished in quantity, the corpuscles, both red and white, were reduced in number, and the red were altered in colour, shape, and size, and there was a tendency to infarction, and not infrequently the gums were swollen and spongy. Abscess of the liver might show no evidence of its existence for years after the patient had returned to Europe. The difficulty of diagnosis in such cases was great, but the facts that the fever did not yield to quinine, that the plasmodium malarie could not be found, and that there was a history of dysentery would be greatly in favour of hepatic abscess. Dr. Anderson referred to statistics as to the relative frequency of dysentery in European and native troops, 25 per 1000 being the rate in the former and 38 per 1000 in the latter, but in the same year the mortality from abscess of the liver was 32 times greater in Europeans than in native soldiers. An attack of dysentery was the most common precursor of liver abscess. He suggested that the difference was accounted for by the difference in the diet and habits of the respective races—as the natives did not eat meat or take alcohol. Sprue, or psilosis, was another disease which would long remain latent, and his experience was that these cases tolerated fruit well and that it formed an important addition to the milk food.

Dr. G. THIN said that it was of considerable importance in selecting individuals fit for tropical life to take into consideration the relation of the body-weight to the height, for his experience had been that the tall, under-weighted man was extremely likely to break down within the first 10 years of tropical life. He referred to the so-called after-effects of malaria and said that in many of these cases the plasmodium could not be found in the blood, that quinine did them no good, and that the only mode of treatment was rest in bed. Many of these cases which he had observed had eventually been proved not to have been of malarious origin.

Mr. J. CANTLIE referred to the relation of dysentery to hepatic abscess. Many of these abscesses were situated above the liver and he believed that they were often due to chill.

Dr. LAURIE said that many diseases which were attributed to climate were in reality due to errors in diet and he gave striking instances of this fact.

Dr. ANDREW DUNCAN referred to tuberculous disease in India and said that much depended on the locality. He had seen some cases do very well. In the Punjab, however, patients did badly, and in Gourkas who became infected the disease ran a most rapid course. He was of the opinion that a man who had once been invalided home for dysentery should not again return to India, and he was of the same opinion with regard to patients who had suffered from sunstroke. Persons of a nervous temperament should not go to India, and he considered that no soldier should be sent out until he was 25 years of age, remarking in support of this statement that during the march from Cabul to Candahar it was the recently arrived drafts of young men who had to fall out.

## OBSTETRICAL SOCIETY OF LONDON.

*Pregnancy of Four and a Half Months complicated by Epithelioma of the Cervix Uteri.—Pernicious Vomiting in Pregnancy.—Exhibition of Cases and Specimens.*

A MEETING of this society was held on Dec. 4th, Dr. PETER HORROCKS, the President, being in the chair.

Dr. R. SANDERSON read a paper on a case of Pregnancy of Four and a Half Months complicated by Epithelioma of the

Cervix Uteri in which he had performed vagino-abdominal hysterectomy. Finding that the epithelioma was operable he removed the uterus and the growth by a combined vaginal and abdominal operation without previous induction of labour. The specimen and microscopic section of the growth were described and shown. He discussed the ethics and the treatment adopted under the following heads—(1) that where pregnancy and operable cancer of the cervix co-exist the life of the mother is alone to be considered; (2) that anterior to the fourth month of pregnancy vaginal hysterectomy is the orthodox treatment; (3) that after this period the alternative methods are (a) induction of labour followed by vaginal hysterectomy, and (b) hysterectomy, without induction of labour, by a combined vaginal and abdominal operation; and (4) that the latter of these alternatives, having regard to the improved statistics of abdominal hysterectomy, was in this case to be preferred.—Dr. W. W. H. TATE congratulated Dr. Sanderson on the successful result of his operation. He thought, however, that it was not necessary to have subjected the patient to the risk of a vagino-abdominal hysterectomy, and that the operation might have been more safely performed by the vaginal route alone. By making a longitudinal incision through the cervix and emptying the uterus of its contents it was possible to remove a uterus in which the pregnancy had advanced to the sixth month, if not later. Six years ago he (Dr. Tate) had treated a case of carcinoma of the cervix complicating a five months' pregnancy by the older method of inducing abortion and removing the uterus per vaginam 10 days later. Although the case was a favourable one for operation, the disease rapidly recurred.—Dr. J. H. DAUBER thought that time alone would decide whether the operation that had just been described afforded the patient a longer period of immunity from recurrence than the more usual method of procedure in these cases. That operation was the best which came nearest to effecting a real and permanent cure. He would like to know in three or five years' time if Dr. Sanderson's patient were alive and well, and he hoped that the society might be informed on that point. He himself had had a similar case under his care in 1898. He emptied the uterus and then waited for its involution, when he performed vaginal hysterectomy. Recurrence occurred within 18 months. This he considered unsatisfactory. The foetus was destroyed and the mother did not long survive.—Dr. W. S. A. GRIFFITH agreed that vaginal hysterectomy after emptying the uterus was at present the best operation, the mortality being very low and the prolongation of life in many cases being considerable.—Dr. AMAND J. M. ROUTH said that vaginal hysterectomy could be performed at a much later date than that of a four months' gestation. By incising the anterior uterine wall along its centre as it was pulled down into the vagina the contents could be readily evacuated. The uterus promptly retracted and its size became so materially diminished that its removal became easy by the vaginal route. The alternative procedure to this operation in such a case would be somewhat as follows: firstly, a temporary removal of the cervical growth by scissors, gouge, or cautery, treating the stump with pepsin dressings to digest any sloughs; secondly, induction of abortion; and thirdly, in a week's time, to allow some involution to take place, vaginal hysterectomy. In early pregnancies he much preferred the former plan. In every case the uterus should be emptied before removal per vaginam.—Dr. HERBERT R. SPENCER agreed that it was not necessary to resort to abdominal section in this case. In a recent paper by E. Altherthum, who had himself performed vaginal hysterectomy for cancer at the sixth month, a list of 18 cases was given in which the uterus was thus removed, all the patients recovering. Nevertheless there was a tendency at the present time to operate by the abdomen in these cases, not for the simple removal of the uterus as in Dr. Sanderson's case, but in order to remove the broad ligament and glands as widely as possible. This operation received support from the researches made in Professor Rosthorn's clinic which showed that 57.5 per cent. of cases of cancer of the cervix in the operable stage already had the glands infected, and therefore a vaginal operation would be useless from the point of view of cure. If these researches were confirmed they would considerably alter their views upon the treatment of cancer of the uterus. As far as he knew the results had not been good, but a sufficient time had not elapsed to allow them to judge of the chances of "cure." At the present

time he (Dr. Spencer) believed that in the case under discussion a better operation would have been high amputation with the cantery followed by removal of the ovum. He thought also that high amputation after induction of abortion was a good operation, if the growth was not in a septic condition. He had not had a case of early pregnancy complicated by cancer in an operable stage; but in three cases of cancer complicating labour he had amputated the cervix and part of the lower segment after delivery and the patients were now well after eight and a half, six, and five years. He did not know of such good results after any kind of hysterectomy for cancer complicating pregnancy.—The PRESIDENT agreed that it was nearly always justifiable to consider the mother alone when both she and the child could not be saved, though he thought that it might so happen that it would be justifiable to save the child. He could not help agreeing with those who advocated the vaginal route, and even where the uterus was too large, as when the child was viable, he advocated the induction of labour and then waiting until involution had proceeded far enough to allow of vaginal extirpation. Moreover, in the earlier states of pregnancy he considered it bad practice to try to drag an unemptied pregnant uterus through the opening made in the vaginal roof; it was far better to remove the contents, thereby reducing the bulk of the uterus to a minimum before extracting it. The removal of the cancerous mass first, leaving the uterus to be dealt with afterwards, had not been considered by Dr. Sanderson, but he agreed with Dr. Routh that it might in some cases be practised with advantage. In operating he used numerous short forceps, grasping very little tissue and removing them in 30 hours. In this way by the help of formalin douches offensive discharges following upon the operation were reduced to a minimum.—Dr. SANDERSON, in reply, recognised the justice of the criticisms in the debate on this case. He, however, found it difficult to understand why a combined hysterectomy should be a more severe operation than a vaginal or an abdominal one. Whether the cervix was circumcised from below or from above, as in Doyen's operation of abdominal hysterectomy could make little or no difference in the severity of the operation; and he believed that in the future, as abdominal methods improved, the abdominal or combined route would be preferred to the vaginal.

A short paper by Dr. J. P. MAXWELL of Changpoo, China, was then read, on two fatal cases of Pernicious Vomiting in Pregnancy.—This was discussed by the PRESIDENT.

A report of the sub-committee upon the President's specimen of Deciduoma Malignum was then received.

The following cases and specimens were shown:—

Dr. CUTHBERT H. J. LOCKYER: Two Septicæmic Uteri, with bacteriological investigations.

Dr. GRIFFITH: A Person of Uncertain Sex.

Dr. C. HUBERT ROBERTS: A case of Male Pseudo-Hermaphroditism.

Dr. AMAND ROUTH: Tubal Gestation where Rupture occurred during the Process of Tubal Abortion; Operation; Recovery.

Mr. H. S. STANNUS (introduced by Dr. TATE): A case of Orbital Tumour in a Hydrocephalic Foetus with Hydramnios.

The specimens were discussed by the PRESIDENT, Dr. G. F. BLACKER, Mr. A. C. BUTLER-SMYTHE, Dr. C. J. CULLINGWORTH, Dr. F. J. MCCANN, Dr. G. H. DRUMMOND ROBINSON, and Mr. J. H. TARGETT.

## LIVERPOOL MEDICAL INSTITUTION.

### *Exhibition of Cases.—A Series of Various Foreign Bodies.*

THE fourth meeting of the session of this society was held on Dec. 5th. Mr. EDGAR A. BROWNE, the President, being in the chair.

Mr. ROBERT JONES showed two cases of Congenital Elevation of the Scapula and stated that the condition was first described by Sprengel in 1890 and was known as "Sprengel's deformity." It consisted of an elevation of the scapula above the level of its fellow, accompanied by rotation, approximating the lower angle to the middle line, with limitation of scapular and humeral motion and sometimes with a slight curvature of the spine. The etiology of the affection was doubtful, but the probability was in favour of constrained foetal position. The first case was that of a boy, aged five years. The deformity was noticed when he was

vaccinated at the age of three months. The child was weird-looking, and he walked with a stoop and carried his head slightly bent to the left side. The left shoulder was raised two inches above the right. The distance from the inferior angle of the scapula to the spinous process of the vertebra was one and a half inches, on the right side it was two and a half inches. The left superior angle was three-quarters of an inch from the spine, the right being two inches. The scapula was therefore rotated. The length of the posterior border of the left scapula was four inches and that of the right five inches. From the left acromion to the episternal notch measured three and three-quarter inches; from the right four inches. The arms were of equal length. The dorsal spine was slightly curved, the convexity pointing backwards. There was a marked limitation in the movement of the scapula. Rotation of the arm was normal and abduction and adduction were limited. The trapezius muscle was contracted and tight. No exostosis could be felt and there was no articulation with rib or spinous process. The second case was that of a girl, aged seven years. The left scapula was displaced upwards, its lower angle touching the fifth rib, whereas the right touched the seventh rib. The movements of the shoulder were limited, so that the arm only came up to a right angle without movement of the scapula; she could not place the hand on the back of the neck. The right scapula, as shown by the radiogram, was normal in site and structure. The left or displaced bone had the axillary border shorter and more curved than that on the opposite side. The posterior border consisted of an upper portion, with which the extraneous portion of bone articulated, and a lower portion which was nearly straight. At the junction of these two portions there was a distinct projecting angle. The abnormal portion of bone was triangular, its outer border articulating with the upper portion of the posterior border of the scapula and its inner angle with a spinous process of the cervical vertebra. The extraneous portion of bone was removed in order to increase the range of scapular movement and the operation proved successful. Examined three years later the patient had improved much and she stood with shoulders square. There was a projection of the upper and inner angle of the scapula and this still interfered with the movement of placing the hand behind the back of the neck. The deformity was noticed a month after birth.

Mr. JONES also showed a case of Congenital Dislocation of the Shoulder and remarked on the literature, stating that cases described might be grouped into those due to faulty development and those due to injury during birth. The patient, aged nine years, showed the head of the humerus displaced backwards under the acromion and rotated inwards, so that the rounded portion was felt posteriorly. On pressing in front the inner margin of the glenoid cavity was felt. The condyles of the humerus pointed antero-posteriorly as the arm fell by the side. Measurements: the length of the posterior border of the left scapula, five inches; of the right, four and a half inches; from the angle of the scapula to the left acromion, six inches; to the right, five and a half inches; the posterior border of the left scapula, five and a quarter inches; of the right, four and a half inches; the arm from the apex of the right acromion to the external condyle, seven and three-quarter inches; and from the left acromion, nine inches. There was an elevation of the scapula and on fixing it the humerus could be slightly abducted, but not adducted. The range of scapular movement was increased, so that in spite of humeral fixation the boy could place his hand both behind his head and behind his back. A radiogram showed the glenoid to be thickened, not due to exostosis, but to the new socket formed on its posterior aspect. The head of the humerus was smaller than its fellow and the shaft was attenuated. Mr. Jones classed the case amongst the co-natal traumatic displacements, and as to treatment he trusted to stretching exercises.

Dr. W. B. WARRINGTON brought forward two cases. The first was a case of Acute Pneumonia characterised by long duration and an intermittent type of pyrexia, the crisis not occurring until the nineteenth day. This condition suggested that the case might be acute phthisis beginning with acute pneumonia. The symptoms were profuse sweating, progressive emaciation, and hæmorrhage. The subsequent course of the disease showed that a migrating pneumonia, possibly due to influenza, had to be dealt with. The second case was one of Acquired Hydrocephalus in a man, aged 35 years. The patient for eight months showed signs of cerebral tumour—viz., marked optic neuritis with headache and some vomiting, tremors in the tongue, slight

exophthalmos of one eye, and weakness in the legs. His mental faculties became markedly impaired and he gradually passed into a comatose condition. At the necropsy dilatation of the lateral ventricles was the only gross lesion found; the microscope showed inflammatory thickening of the ependyma of the fourth ventricle. The nature and diagnosis of such cases were briefly discussed.—Dr. T. R. GLYNN briefly remarked upon the second case and related a case similar to it in which there were marked optic neuritis, headache, reeling gait, staggers, &c., a diagnosis of cerebellar tumour being made. The patient was trephined over the cerebellum. No tumour was found, but some cerebro-spinal fluid escaped after opening the ventricle and the patient recovered. Such cases explained those instances of recovery from apparent cerebral tumour.—Mr. DAMER HARRISON related a similar case of relief of symptoms after opening the lateral ventricle.

Mr. RUSHTON PARKER read a note on a Series of Fourteen Foreign Bodies, various in nature and locality, and remarked that some foreign bodies were mere curiosities more or less amusing; others, while extraordinary, were curious from the little harm they did; while others, commonplace in themselves, might be the cause of danger and even of tragedy. The cases were with one exception from his own practice. 1. A wooden splinter over two and a half inches long and from a quarter to half an inch in width and thickness, embedded in the pterygo-maxillary region of a man, where it was broken off a bundle of swinging boards that struck him in the right lower eyelid. The object was thought to be loose bone and was withdrawn after a few weeks, early in 1878. 2. A piece of sailor's knife blade, two and a quarter inches long and three-quarters of an inch wide, broken off in the left pterygo-maxillary region of a man who was stabbed in New York. The object was removed 14 days later at the Liverpool Northern Hospital by Mr. Chauncey Puzey in 1879. 3. A gun-breech and a screw-bolt, forced by the bursting of a fowling-piece into the middle of the owner's face and lodging five years in the nose, which were removed through an incision under the upper lip on Dec. 20th, 1883. The objects weighed three and a half ounces and measured three inches by one and a half inches by one inch. 4. A piece of parasol rib, three inches long, broken off in a woman's forearm and removed after 12 days. 5 and 6. These were cases in which a bullet was displayed by radiography and removed from subcutaneous regions of the leg and hand respectively in boys. 7. Radiograms of a small bullet which was flattened against the lower end of the radius in a young man. When seen two days after the accident the wound was healed and the bullet was left alone. Five years later no inconvenience had been caused and the bullet was radiographed again. 8. Radiogram of a leaden pellet from an air-gun between the metacarpal bones. The substance was removed a fortnight later as it caused annoyance and apparently pressed on a nerve. 9. A photograph of a piece of red-rubber catheter over three inches long encrusted with phosphatic calculus which had been taken from the bladder of a man, aged 71 years. The calculus was crushed and evacuated and the catheter was removed by lithotrite. 10. A photograph of a silver tooth-plate measuring two inches by one and a quarter inches extracted from the pharynx of a man, aged 36 years, after nine hours. 11. A photograph of a tooth-plate, vulcanite and metal, with attachment hooks, measuring two inches by one inch by one inch, which had been swallowed and which was removed eight days later by œsophagotomy with success. 12. An iron staple one inch long and one inch wide which had been swallowed by a boy. A radiogram showed it to be lying in the pelvis three days later and it was passed per anum on the next day. 13. A piece of turned oak, seven inches by half an inch by three-quarters of an inch, known as a "knitting-sheath," which was removed from the rectum of a man, aged 70 years, after a fortnight. No harm resulted. 14. Radiograms of the ankle of a girl, aged 15 years, showing a piece of glass broken off a strip of window-glass one inch long, more than one-eighth of an inch wide, and less than one-eighth of an inch thick. The object had been there five years, causing slight but very persistent disability of the ankle-joint; it was removed with an end to all trouble. A radiogram was shown of the parts after removal of the glass.—Mr. DAMER HARRISON, Dr. W. ALEXANDER, Dr. C. A. HILL, and Professor H. BRIGGS related instances of other foreign bodies and commented upon some of Mr. Parker's series.

## LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

*Axis-traction Forceps in Midwifery.—Resonance to Percussion over Ovarian Tumours.—Exhibition of Cases, Pathological Specimens, &c.*

A MEETING of this society was held on Dec. 6th, Dr. A. G. BARRS, the President, being in the chair.

Dr. J. B. HELLIER read a paper on the Use of Axis-traction Forceps in Midwifery. He briefly sketched the development of the midwifery forceps, demonstrating the need of the third or perineal curve. He described the points requisite for the construction of an efficient traction instrument and showed and criticised various patterns now on the market. He examined the objections urged against such instruments in several modern works on midwifery and alleged that the difficulty of application could be very easily overcome. It was quite a mistake to assert that in any way the prognosis to the child was less favourable than when ordinary forceps were employed. Axis-traction forceps were suitable for low cases as well as high. He believed that if anyone who had had experience of old patterns would use the axis-traction forceps sufficiently to become familiar with their application and would apply them in a few really difficult cases they would not again abandon their use.—Mr. C. J. WRIGHT, Dr. J. BRAITHWAITE, Dr. E. O. CROFT, and Mr. J. W. DRAPER took part in the discussion, and Dr. HELLIER replied.

Dr. E. O. CROFT read notes of cases illustrating Resonance to Percussion over Ovarian Tumours. He said that the chief conditions which might give rise to a resonant note over the situation of an ovarian tumour had been described thus: (1) by intracystic changes producing gas, such as decomposition of contents after tapping or suppuration associated with gas-forming bacilli; (2) by the entry of air into a cyst from a communication with the bowel produced by the breaking through of an adherent portion; and (3) by the displacement forwards of coils of intestine and their adhesion to the front of the tumour. The following illustrative cases were described. In the first case, that of a married woman, aged 27 years, the mother of one child who was born seven years previously, abdominal enlargement was noticed about 18 months before. She had "caught cold" during menstruation which was arrested. Three months afterwards a severe attack of peritonitis occurred. The tumour was then discovered and there were normal physical signs of an ovarian cyst of about the size of a child's head. The symptoms were subsiding and operation was therefore postponed. A few weeks later the outline of the cyst could be felt as before, but over its whole area the percussion note had altered to one of tympanic character. Ovariectomy was performed. The tumour, with twisted pedicle and many adhesions, was found to be full of fetid gas. Only a very small amount of foul pus existed in its lowest pocket. There was no opening of communication with any portion of bowel. The gas was evidently produced by gas-forming bacilli associated with suppuration, the infection probably having gained access by means of the damaged vitality of the adherent portion of bowel wall. The patient made a good recovery. Unfortunately a bacteriological examination was not made. The second case was that of a married woman, aged 38 years, who had undergone two pregnancies, the last one 10 years ago. For four or five years she had suffered from severe attacks of abdominal pain at intervals. About 12 months ago she had had an attack of peritonitis and about one month before operation a more severe attack. Menstruation was regular throughout. On examination the abdomen was seen to be enlarged by an obvious cystic tumour. On percussion a central area of dullness existed with the umbilicus at its centre. The area of dullness was distinctly surrounded by tympanic areas in the epigastric, in both the hypochondriac, and in the lumbar regions, but in addition a broad tract of tympanic resonance existed across the iliac and hypogastric regions. The physical signs were thus suggestive of a pancreatic or mesenteric cyst. A pelvic examination revealed, however, the fact that when the uterus was pulled on by vulsellum forceps it dragged on the tumour. A probable diagnosis of ovarian tumour with long pedicle and abnormal relations of bowel was made. The abdomen was opened. The tumour proved to be a large dermoid of the left ovary embedded in adhesions. The pedicle was twisted so that the original left surface of the tumour had passed

across anteriorly to the right and in doing so had drawn with it a mass of adherent bowel which was found lying across the lower half of the front of the tumour. The tumour was removed and the patient recovered.—The PRESIDENT, Mr. H. LITTLEWOOD, and Dr. HELLIER discussed the paper and Dr. CROFT replied.

The following cases, pathological specimens, &c., were exhibited:—

Dr. HELLIER: (1) Various Patterns of Axis-traction Forceps; (2) Vesicular Mole which caused Hyperemesis Gravidæ; (3) two specimens of Early Adeno-carcinoma of the Fundus Uteri removed by vaginal hysterectomy; and (4) Schultz's Obstetric Phantom with an appliance for contracting the pelvis.

Mr. LITTLEWOOD: (1) Erosion of the Knee-joint for Tuberculous Disease (a man, aged 40 years); (2) three sets of Uterine Appendages removed for salpingitis associated with ovarian cysts; (3) photograph of an enormous Inguinal Hernia; and (4) (with Mr. T. CARTER) a case of Excision of the Upper Jaw (the patient was fitted with an obturator).

Dr. C. M. CHADWICK and Mr. EDMUND ROBINSON: Purpuric Eruption of 30 years' Duration.

Dr. CHADWICK: (1) Unusual Skin Condition; (2) Enlarged Spleen with Hemiplegia in a patient who had suffered from Malta fever; and (3) Chorea in a Child, aged three years, following on Acute Rheumatism with Involvement of the Mitral Valve.

Dr. T. WARDROP GRIFFITH: (1) A case of Acquired Syphilis in a Child; and (2) a specimen of Extensive Rheumatoid Arthritis.

Mr. G. CONSTABLE HAYES: (1) Two cases showing Remains of Pupillary Membrane; and (2) a case of Detached Retina with Hæmorrhages in a Boy, aged eight years.

Mr. B. G. A. MOYNIHAN: (1) Several specimens of Renal Calculi; (2) specimens from three cases of Partial Nephrectomy—two solitary cysts and one tumour of doubtful nature; and (3) specimens from cases of Complete Nephrectomy—(a) papillomata of the pelvis of the kidney, (b) growth of suprarenal capsule involving the kidney, and (c) cystic kidney.

Mr. MAYO ROBSON: Uterus with a Fibro-myoma expanding the Layers of the Broad Ligament.

Dr. H. J. CLARKE (Doncaster): An Abnormal Premature Fœtus.

Dr. E. F. TREVELYAN: (1) A case of Profuse Hæmatemesis in a man (treated with gelatin); (2) an unusual case of Wasting of the Muscles of the Forearm; (3) a case of Functional Intentional Tremor of the Arm; (4) a case of Graves's Disease with a previous history of acute insanity; (5) a case showing Retrogression of Marked Cerebral Symptoms with the exception of the papillitis which had passed into atrophy (? quiescent tuberculous tumour); and (6) a case of Laryngeal Paralysis.

## EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

*Exhibition of Cases.—Temperature of Phthisis.—Suprapubic Prostatectomy.*

A MEETING of this society was held on Dec. 4th, Professor T. R. FRASER, the President, being in the chair.

Dr. W. ELDER and Dr. A. MILES showed a patient after the removal of a Tumour from the Left Prefrontal Lobe of the Brain. The case was that of a man, aged 47 years, who became more and more apathetic, dull, and emotional until he became comatose. There was an indefinite history of syphilis. As he appeared to be dying the skull was trephined and an apparently organised gumma was shelled out from the left prefrontal lobe. He made an excellent recovery.

Dr. G. LOVELL GULLAND and Dr. A. LOGAN TURNER showed a patient after operation for Laryngeal Tuberculosis.

Mr. JOHN SHAW M'LAREN exhibited a patient after recovery from a Compound Depressed Fracture of the Skull and Lepto-meningitis.

Mr. DAVID WALLACE, C.M.G., showed Beckmann's Apparatus for ascertaining the Freezing-point of Blood.

Dr. D. LAWSON of Nordrach-on-Dee read a paper entitled, "Some Clinical Observations upon the Temperature of Phthisis based upon Experience of 100 Consecutive Cases treated by Open-air Methods." Progress towards arrest in an active lesion was characterised, he said, by well-marked clinical phenomena which appeared and were maintained simultaneously. Weight was gained, the pulse-rate fell, the respiration-rate fell, and the temperature fell by lysis and diminished in amplitude. In one case of acute fibro-caseous tuberculosis in a male, aged 22 years, the treatment extended over six months. During this time the pulse-rate fell approximately from 95 to 78 and the respiration-rate from 23 to 13. The amplitude of temperature variation was diminished by almost 1° C. (1.8° F.), and the net gain in weight was 17 pounds. If these phenomena were not associated there were grounds for apprehension. Thus he had seen on more than one occasion death occur after a considerable gain in weight. In one case, although the patient's condition was critical, yet in one week he gained five pounds in weight and within a few days of his death he actually weighed over 12 pounds more than when he first came under observation, while in reality he was losing ground. In another case the truth of the observation that deviation from the general rule was unfavourable was even more marked. Not only was a gain in weight observed, but also a fall in temperature, while the case was steadily going downwards, and the presence of Ehrlich's diazo-reaction was an extremely unwelcome factor. The temperature in phthisis was characterised by two qualities—(1) inelasticity and (2) instability. By inelasticity was meant that tendency which a temperature exhibited when disturbed by any exciting cause to remain in the altered condition after the withdrawal of the disturbing factor. This was illustrated by several charts relating to phthisical patients after such exercise as hill-climbing. By instability was meant a marked sensitiveness to reaction, an extreme liability to become disturbed in the presence of apparently trivial influences, influences so slight that they produced practically no effect on the temperature in health. Among those might be cited slight derangements of the digestive or nervous systems or marked variations in the surrounding atmospheric temperature. The rectal method of taking the temperature was incomparably more reliable than any other and should be adopted in every case of pulmonary phthisis except in those where there were local complications such as hæmorrhoids or ischio-rectal abscess. The rectal method had the following advantages: (1) in some cases of genuine relapse the rectal temperature rose some time (even as much as 12 hours) before the thermometer gave any indication elsewhere; (2) it rose higher both relatively and absolutely at such times than the temperature elsewhere; (3) it was disturbed by trivial factors, such as slight indigestion and nervous causes which often did not affect the axillary range; and (4) it was especially serviceable in connexion with the question of when to begin and how to regulate a patient's exercise. In some of these cases the axilla as a guide was quite worthless and the mouth was nearly so. In every early case of phthisis the temperature ought to be recorded at least four times daily. Temperature in relation to exercise was a complicated and intricate question. It had been customary to assume (1) that exercise always caused a rise in the tuberculous subject, and (2) that a temperature of 98.6° F. at 8 A.M. contra-indicated exercise. These statements were for the most part true, but they were open to many exceptions. Dr. Lawson stated that the effect of exercise on a tuberculous subject might be either to depress the temperature or to raise it. A chart showing the typical subnormal range of temperature in an ordinary case of fibroid phthisis was shown. The patient was kept at rest, and the temperature at one point was about normal. Under a walk of one and a quarter miles the temperature fell 1° C. When again this was discontinued the temperature rose to the level which it first occupied. Doubtless the low temperature in this case represented a temperature of exhaustion brought on by the exercise, small in amount though it was. It was an example of exercise producing a fall in temperature. In another fibroid case with distinct cavity formation present the patient was kept in bed because her morning temperature was 98.6° F. She had gained 20 pounds in weight in eight weeks, but as no improvement otherwise took place exercise was begun and gradually increased until she walked four miles daily. Marked improvement took place and the temperature fell almost at once. Exercise usually raised the temperature; it

did so in about three cases out of four. Of much more importance, however, than the extent of the rise was a characteristic of that rise (first recognised by Bardswell), already alluded to as the elasticity of the tuberculous temperature. If the exercise taken had not transgressed the limits of beneficial exercise the temperature would invariably fall to 37° C., or very near it, during the next hour. Should it fail to do so there were good grounds for caution, and limitation in the rate and extent of the exercises was indicated.—Dr. ALEXANDER JAMES, Dr. GULLAND, and Dr. WILLIAM TAYLOR took part in the discussion.

Mr. WALLACE read a paper on Suprapubic Prostatectomy with notes on 13 cases. He said that a patient might suffer from all the symptoms of prostatic hypertrophy and yet the gland might not be enlarged. This fact had led Poncet to divide cases of prostatism into two groups—(1) those due to enlargement of the prostate mechanically interfering with the outflow of urine; and (2) those due to septic conditions, without enlargement of the prostate, but presenting symptoms similar to those with enlarged prostate. This difference in cause at once led to a difficulty in diagnosis and in the determination of suitable treatment. A consideration of symptoms alone could not determine whether the prostate was enlarged. Enlargement of the gland detected on rectal examination did not necessarily imply mechanical obstruction to the urethral orifice. An apparently small prostate might yet possess an intra-vesical enlargement which might impede urination. At the outset, therefore, much difficulty might be experienced in judging of the condition of the prostate, and the plea for suprapubic cystotomy was strengthened from the standpoint of diagnosis. The view of Guyon, that "the radical treatment of enlarged prostate does not nor cannot exist," still held in the sense that no one method of treatment could be termed "radical" when applied to all cases. The etiology of hypertrophy of the prostate had not yet been satisfactorily determined. The view upheld by the French school that the enlargement was secondary to arterio-sclerosis was untenable. Whatever might be the origin of the enlargement it was often due to the formation of masses of glandular tissue which formed fibro-adenomatous or fibro-myomatous tumours similar to those occurring in the uterus. Three varieties of enlargement might be recognised—(1) vascular, (2) fibrotic, and (3) fibro-adenomatous or fibro-myomatous. Any one of these might act mechanically to produce bladder changes and those symptoms associated with over-distension grouped together as those of "chronic incomplete retention." Four methods of treatment were at present in use—(1) catheterism; (2) cystotomy—(a) perineal and (b) suprapubic; (3) castration or vasectomy; and (4) prostatectomy—(a) perineal and (b) suprapubic. Personally Mr. Wallace thought that the catheter should be used if possible only in those cases where the condition had not reached atony of the bladder, and castration or vasectomy only in those cases where catheterisation had become more difficult or associated with cystitis or bleeding which had come on subsequently to the use of the catheter. He recognised that castration and vasectomy had met with much success, but both had the great disadvantage that accurate diagnosis was not possible, and if either failed to relieve the symptoms time had been lost and the patient after all had to submit to cystotomy. Besides, the mortality of castration was as high as was that of prostatectomy if all cases were considered. Perineal cystotomy could very seldom, if ever, be a better or safer procedure than suprapubic cystotomy. The latter was particularly advantageous, as it enabled the condition within the bladder to be seen precisely. The bladder could be drained by Cathcart's adaptation of the Sprengel pump with the knowledge that the bladder wall would contract and in many cases would recover ultimately its expulsive power. If need be, prostatectomy might be performed or prostatectomy might be adopted. With regard to the latter, much depended on the condition of the prostate. A middle lobe was readily removed; large adenomatous growths could be enucleated, and these were the favourable cases to treat by this method. Mr. Wallace did not believe that all prostates were suitable for even partial removal, and he believed that complete removal of the prostate without opening into the urethra was an anatomical impossibility. This operation, which seemed so natural, had not been so universally adopted even in suitable cases as might have been expected. The factors which influenced surgeons against it, he thought, were: (1) the supposed danger of suprapubic operations; (2) the relief given to patients

suffering from the effects of enlarged prostate by "catheter life"; and (3) the introduction a few years later of an apparently rational operation (castration). As regards the first objection Mr. Wallace gave his own statistics. He had performed 40 operations for very different conditions—tumours, calculi, tubercle, and enlarged prostate. In the majority the urine was septic, while in many the patients were very ill. Amongst these there were five deaths, giving a percentage mortality of 12.5. Two of these deaths occurred in cases of tuberculous bladder, one in a case of vesical tumour, one in a case of septic cystitis plus stricture, and one in a case of simple prostatectomy. These figures showed that suprapubic cystotomy *per se* was not dangerous. The operation was easy and rapid and with reasonable care the peritoneal cavity was safe. If there had been atony of the bladder it might be drained for from three to four weeks. Mr. Wallace then shortly described 11 cases in which he had performed prostatectomy.—Mr. J. M. COTTERELL, Mr. C. W. CATHOART, Dr. A. G. MILLER, and Mr. A. A. SCOT SKIRVING took part in the discussion which followed.

## ROYAL ACADEMY OF MEDICINE IN IRELAND.

### SECTION OF OBSTETRICS.

#### *Suppurating Ovarian Cyst.—Posterior Vaginal Celiotomy.*

A MEETING of this section was held on Nov. 22nd, Dr. W. J. SMYLY, the President, being in the chair.

Dr. H. JELLETT read a paper entitled "Notes on a Case of Suppurating Ovarian Cyst complicated with a Large Intraperitoneal Abscess." The patient, who was 38 years of age, was admitted to Sir Patrick Dun's Hospital on July 27th, 1901. She was then in a very critical condition owing to the presence of a tumour which occupied the lower portion of the abdomen. She had been ill for five weeks, her temperature was 101° F., and her pulse varied from 100 to 120. Opening the abdomen resulted in the evacuation of a large collection of most fetid pus, which had accumulated in the peritoneal cavity, among the intestines. The cavity was then washed out and plugged. The existence of a tumour in Douglas's pouch was also determined, but it was not removed owing to the state of the patient making it necessary to shorten the operation as much as possible. The condition of the patient after the operation was very serious and the discharge which escaped from the cavity was most offensive. The cavity was washed out twice daily with sanitas and water (25 per cent.) and the fœtor disappeared. Her temperature fell to normal on August 8th and the abdominal wound, which had not united, was re-sutured with partial success. However, on Sept. 1st the condition of the patient again became serious. Her temperature rose, she lost her appetite, and there was extreme difficulty in getting the bowels to move. On examination a cystic tumour was found in Douglas's pouch pressing on the rectum. This tumour was removed on Sept. 5th through an opening made in the posterior vaginal fornix. It proved to be an ovarian cyst containing a most fetid accumulation of pus. It had apparently no connexion save with the right cornu of the uterus. This pedicle was clamped, and the cavity was plugged with sponges wrung out of very hot water on account of the large amount of general oozing from separated adhesions. No sutures were used. The sponges were removed on the next day and replaced by iodoform gauze. The patient's temperature fell at once and she steadily and continuously recovered strength. Dr. Jellettt drew attention to the effect of hot sponges in immediately checking hæmorrhage.—Dr. A. V. MACAN, under whose care the woman was during the early portion of her stay in hospital, said that her condition was at that time very critical. He now thought that he should have drained the abdomen through the vagina, but there was a firm mass in Douglas's pouch and the patient's condition was very unpromising.—Dr. ALBERT SMITH and Dr. R. D. PUREFOY also discussed the case.

Dr. HASTINGS TWEEDY read a paper advocating Posterior Vaginal Celiotomy (Prior's operation) as the operation of election rather than that by the Anterior Fornix. After incising the vaginal mucous membrane the wound should be enlarged by means of the fingers which were made to tear an entrance into the peritoneal cavity. The Trendelenburg position was now added to the ordinary gynaecological

position. By this means the pelvic cavity could be well explored by sight, long vaginal extractors being employed to keep the edges of the wound apart. In cases where the vagina was roomy such an operation was simple, safe, and suitable for the removal of inflamed fœtal or other small tumours situated to the side or behind the uterus. The adoption of the Trendelenburg position would be found a distinct improvement in the technique of the operation by those who had previously not employed it.—Dr. MACAN, Dr. PUREFOY, the PRESIDENT, and others discussed the paper.

**CARDIFF MEDICAL SOCIETY.**—A clinical meeting of this society was held on Dec. 5th, Dr. D. R. PATERSON, the President, being in the chair. The minutes of the last meeting having been read and confirmed, on the motion of the President, seconded by the treasurer (Dr. A. P. Fiddian), a hearty vote of congratulation was passed to Dr. W. T. Edwards, the senior member of the society, on his attaining his eightieth birthday, and the President, Dr. Fiddian, and Mr. William Sheen were appointed as a deputation to convey the vote to Dr. Edwards.—The President and Dr. F. W. Evans showed cases of Lead-poisoning with well-marked Paralytic Symptoms.—Dr. H. G. Cook showed a patient with Enlarged Glands in the Neck which had materially diminished after the administration of arsenic.—A discussion took place as to whether the enlargement was tuberculous or lymphadenomatous.—Mr. W. B. C. Treasure showed a patient with Aortic Stenosis and Arrhythmical Tachycardia; the condition followed acute rheumatism and had been aggravated by injudicious cycling.—Mr. Sheen showed a man in whom the Lower Ends of the Tibia and Fibula and the whole of the Astragalus had been removed for advanced tuberculous disease. The joint was entered by an external angular incision, no tendons being divided. The patient now did his work as a telegraph messenger. A skiagraph showed the present condition of the bones.—Dr. P. Rhys Griffiths showed a man in whom he had Dilated a Stricture of the Ureter from the Kidney Pelvis after Nephrectomy. A marked increase in the quantity of urine excreted immediately followed the operation.—Dr. Cook showed a Calculus of the size of a walnut removed from the bladder of a girl, 10 years of age. It blocked the neck of the bladder and was removed by suprapubic cystotomy.—Mr. J. Lynn Thomas showed a photograph of an infant with a very large Occipital Meningocele which he had subsequently successfully removed.—Dr. Athol S. J. Pearse showed a complete and well-dissected specimen of Early Abortion. The decidua formed a complete cast of the interior of the uterus, showing the positions of the os uteri and the openings of the Fallopian tubes. In one upper corner was the sac containing a minute embryo. Dr. Pearse pointed out that such a specimen showed the possibility of menstruation continuing during the earlier months of pregnancy and also the possibility of a sound being passed without damaging the fœtus.—Mr. Sheen showed a photograph and drawing of a case of Vaccination Inoculation on the Cheek simulating Anthrax.—Dr. Ewen J. Maclean showed a specimen of Sarcoma Uteri which recurred four times in 10 months. Vaginal hysterectomy was performed. Death finally resulted. An interesting point was the occurrence of an implantation inoculation of the growth on the posterior vaginal wall.—Mr. E. Tenison Collins showed a specimen of Sarcoma Uteri with an attached Cystic Right Ovary, the whole being removed by vaginal incision. The patient did well.—Dr. Eldon Pratt described specimens of Duodenal and Typhoid Ulcers. He pointed out the evil of moving patients when the acute symptoms were present. This was illustrated by his cases.—Mr. Cornelius Griffiths showed skiagrams of Fractured Legs and Patellæ illustrating the transparency of callus of some duration. The medico-legal importance of this and the impossibility of skiagrams of pathological conditions being correctly interpreted by any but medical men were pointed out.—Mr. Tenison Collins described and illustrated by drawings a case of Inversion of the Uterus treated by Haultain's Method, this being, as far as he could ascertain, the second case done. After the abdomen was opened the stricturing part of the uterus was divided, the inversion was reduced, and the wound in the uterus was sewn up. The patient made an uninterrupted recovery.

**NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.**—A meeting of this society was held on Dec. 4th, Dr. E. C

Kingdon, the President, being in the chair.—Mr. A. R. Anderson read notes of, and showed the patient in, the case of a man, aged 47 years, who was admitted into hospital in the early part of this year with Epithelioma of the Skin of the Left Cheek involving the Parotid Gland. He had for years noticed a small lump there like a wart or mole, but it was only recently that it had begun to spread. On admission the ulcer, which was situated just in front of the tragus, measured one and a quarter inches by three-quarters of an inch, and was firmly adherent to the sub-jacent parts. It had a raised, everted, indurated edge and a hard, warty, irregular base, presenting quite a different appearance from the typical rodent ulcer with its slightly raised and scarcely indurated edges and its slightly depressed, glazed, pinkish base. In addition there were a few enlarged glands. The growth was freely excised, and as its base was found to involve the parotid a considerable portion of the gland was removed, as were also the lymphatic glands. The wound healed readily and the patient went home in a few weeks. Early in October he came back with recurrence in the scar-tissue over the cheek. He had now two typical epitheliomatous ulcers, one in front of the tragus, one and a half inches long by one inch broad, the other occupying the site of the tragus and extending for a short way down the meatus. It was evident that nothing short of a serious and extensive operation would suffice to ensure reasonable prospect of success. Treatment with the Roentgen light was begun on Oct. 26th, and continued by daily sittings for 21 days, at the end of which time the ulcers had disappeared and he was apparently cured, their site being occupied by pale, firm scar-tissue. The sittings for the first fortnight were of 10 minutes' duration, being increased during the last week to 15 minutes. A microscopic section of the growth removed at the operation was shown.—Mr. W. M. Willis and Dr. W. B. Ransom spoke on the case and Mr. Anderson replied.—Mr. T. D. Pryce read a paper on the Necessity of Medical Asepsis and Antisepsis. For the purpose of illustration attention was chiefly directed towards enteric fever, in which disease the speaker advocated boiling all excreta and recommended that the necessary utensils should be provided by the municipality who should collect periodically from the houses of typhoid fever patients and destroy such excreta.—The paper was discussed by the President, Dr. H. Handford, Dr. Ransom, and Dr. J. Mackenzie, and Mr. Pryce replied.—Dr. T. Aldous Clinch read notes on two cases of Herpes affecting (1) the first sacral nerve, and (2) the fifth lumbar nerve.—The President and Dr. Ransom spoke on the subject and Dr. Clinch replied.—Dr. Ransom read notes on a case of Intestinal Sand, and showed specimen. The condition appeared to have been the result of eating large quantities of pears, and the symptoms were such as to suggest gall-stones.—The President, Mr. J. Mackie, and Mr. Pryce spoke on the subject, and Dr. Ransom replied.—Mr. Anderson showed a skiagram of a Nail in the Right Bronchus of a Child. He also showed the nail, which was two inches long, and which had been removed by a high tracheotomy. A probe being then inserted the nail was struck at three and a half inches from the wound and subsequently removed with forceps. The patient recovered.—Mr. Willis discussed the case and related that of a child who had been under his care at the Nottingham General Hospital with a central upper incisor lodged in a bronchus. The x rays failed to reveal it. An attack of pneumonia supervened, from which the child recovered, and when convalescent suddenly died. The tooth was found at the bifurcation of the trachea at the necropsy.

**MANCHESTER MEDICAL SOCIETY.**—A meeting of this society was held on Dec. 4th, Mr. A. H. Young, the President, being in the chair.—Mr. W. P. Montgomery made a communication on a case of Acute Duodenal Pressure Obstruction. The patient, a youth, aged 15 years, whose previous health had always been good, was seized with an attack of acute gastro-intestinal catarrh, probably caused by ice-cream. The diarrhoea ceased after 24 hours, but the vomiting continued in excessively large quantities. 48 hours after the onset of symptoms a laparotomy was performed. The dilated stomach filled the whole abdominal cavity. After emptying the stomach and turning it upwards it was found that the duodenum was extremely dilated as far as the point where it was crossed by the superior mesenteric fold. The small intestines were collapsed and pushed down into the pelvis. When these were raised after the emptying of the stomach the duodenal contents passed onwards and

the obstruction seemed to be relieved. The youth died a few hours later and the diagnosis was confirmed by the necropsy. The bearings of this and other cases on so-called acute idiopathic dilatation of the stomach were discussed and the lines of treatment were suggested.—Dr. A. Donald read notes of a case of Oophorectomy for Cancer of the Breast and showed the patient. She was sent to St. Mary's Hospital, Manchester, by Mr. J. Hepworth of Eccles on June 22nd, 1900. She was 46 years of age and had not passed the menopause. The left breast was transformed into a hard mass firmly fixed to the chest wall and to the skin. The growth extended into the axilla. Double oophorectomy was performed on June 23rd. Thyroid treatment was commenced a week before the operation and was continued as soon as convalescence was complete. On Nov. 12th the patient was readmitted. The breast was much smaller and softer and was quite mobile except at one small spot. The mass in the axilla could not be felt. On the 14th the breast, with the axillary glands and a portion of the pectoralis major muscle, was excised. In April, 1901, two small nodules were found in the scar and were excised. On Sept. 4th some hard masses were found in the supra-clavicular region. At the time of reporting the patient's condition was much better than when she was first seen—an interval of nearly 18 months. She had gained weight and had no pain. The nodules in the scar and in the glands above the clavicle were increasing.—Dr. Thomas Harris read a paper on Different Varieties of Stethoscopes, and showed a large collection of different kinds of ancient and modern type. His conclusions were that the attempt to invent a universal stethoscope, either of the monaural or binaural type, which would suit everyone would be sure to be fraught with failure; that what suited one man's ear did not suit another, the consideration of the comfort with which an instrument could be used was much more important than any other detail in the shape of the instrument; that more depended upon the physician than upon the instrument which he used; and that immediate auscultation was too much neglected and was very valuable in many cases. Dr. Harris also referred to a series of experiments which he had made, showing that in the ordinary monaural stethoscope the chief conduction took place through the wood and not through the air column.

**MIDLAND MEDICAL SOCIETY.**—A meeting of this society was held on Nov. 27th, Dr. Arthur Oakes, the President, being in the chair.—Dr. E. S. Nutting and Mr. C. G. Higginson were elected members of the society.—Dr. O. J. Kauffmann showed a Case for Diagnosis. It was that of a girl, aged 11 years, who was affected with a slowly progressing paralysis, with ataxia, which had commenced at the age of eight years. There was no evidence of congenital syphilis and no history of the paralysis following on acute infective disease. The legs were now extremely weak and in spastic extension which was, however, not very rigid; six months ago, when she could still walk a little, there was some reeling ataxia of the gait. The arms were weak and tremulous, the tremors resembling those of insular sclerosis in every respect. There was also a little shaking of the neck and trunk on exertion; no nystagmus had been observed, and her fundi oculorum and pupils were normal. The voice was extremely low and a little nasal, as though there was slight paresis of the soft palate; utterance was very slow and very imperfect, but could not be described as scanning. The ends of the words were clipped and their meaning was understood with difficulty; there was no aphasia. Sensation all over the body was normal. The bladder and rectum were controlled. The mind showed a condition of quiet satisfaction and the face wore a permanent smile. The intellectual development was not that of a child 11 years of age and would have been poor for a child six or seven years of age. Dr. Kauffmann was inclined to regard the case as one of hemispherical cortical degeneration. The view of its being one of hereditary cerebellar ataxia was propounded and the question of insular sclerosis was discussed.—Mr. W. F. Haslam showed a woman, aged 49 years, whom he had treated for Trigeminal Neuralgia by the Injection of Osmic Acid as suggested by Sir William H. Bennett in THE LANCET of Nov. 4th, 1899, p. 1220. The neuralgia had existed for six years and during the latter half of that period the pain had been very severe, while for the last six months it had been almost more than she could bear. Immediate and complete relief

followed the operation, which was performed four months ago, and there had been no return of pain. Mr. Haslam pointed out that though it was too soon to speak positively about the curative effect of the method in this case there was every reason to believe that the results were at least as good as those obtained by the major surgical operations devised for the relief of this terrible condition.—Mr. George Heaton showed a Dentigerous Cyst which he had removed from the lower jaw of a boy, aged 11½ years. The cyst, which was of the size of a pigeon's egg, contained clear straw-coloured fluid. A bicuspid tooth of the permanent set was fixed in its wall with the crown projecting into the cavity of the cyst. The fangs of the tooth were ill-developed. The cavity left in the jaw was packed with gauze and closed up by granulation.—Dr. C. E. Purslow read a paper on Acute Hydrannios, and Mr. Leedham Green a paper on the Closure of Traumatic Defects of the Skull.

**ÆSCULAPIAN SOCIETY.**—A meeting of this society was held on Dec. 6th, Dr. Arthur T. Davies, the President, being in the chair.—Dr. Sydney P. Huggins showed a specimen of Intestinal Obstruction due to Meckel's diverticulum removed from a boy, aged two years and 11 months, who succumbed 36 hours after the onset of abdominal pain and vomiting and very shortly after being first visited.—Mr. Harold Barnard showed two similar specimens. One of these, from a child, three months old, was complicated by the presence of an inguinal hernia. The patient who was almost dead when operated upon died soon after the operation for the relief of the inguinal hernia.—Dr. Leslie Durno read notes of Drug Rashes. 1. In a robust man two pills of ipecacuanha with squill (P.B., 1898) induced great skin irritation, erythema, swelling, petechiae, and desquamation lasting 14 days. 2. Tinnitus, vomiting, and desquamation of the skin of the face following two-grain doses of quinine three times a day. 3. Copaiba rash in a youth in whom desquamation continued for three weeks. 4. A rash, like measles, lasting a few hours following a dose of calomel.—Dr. L. V. Young related a case of an Iodide Rash following the taking of five grains of iodide of potassium thrice daily for four days which bore a very close resemblance to variola. In this there were oedema of the eyelids, papules, vesicles, and pustules present at the same time on different parts of the body and together on the head and face. Recovery was not complete in two months.—A general discussion followed.

**IPSWICH CLINICAL SOCIETY.**—A meeting of this society was held on Nov. 14th.—A very interesting lantern demonstration was given by Dr. J. Purves Stewart on the Value of Inspection in the Diagnosis of Nervous Diseases. Slides were shown illustrating the following:—posture in organic hemiplegia; contrast with functional hemiplegia; athetosis; pes cavus; the plantar reflex; normal flexor response and abnormal extensor (Babinski's) response; posture in paralysis agitans; hypertonia in tabes rendering abnormal postures of the limbs possible; posture in lesions of the cervical enlargement, especially of the fifth and sixth cervical segments; ruptures of the brachial plexus, their association with paralysis of the cervical sympathetic if the lowest roots of the plexus were torn; diagnosis of lesions of various cranial nerves by inspection; lesions of the crus cerebri; lesions of various spinal nerves; and posture in pseudo-hypertrophic paralysis, &c.—At the close of the lecture a very hearty vote of thanks to Dr. Stewart was proposed by Mr. R. W. Brogden and seconded by Mr. Branford Edwards.

**ROCHDALE AND DISTRICT MEDICAL SOCIETY.**—At a meeting of this society held on Dec. 5th Dr. Ernest S. Reynolds gave a lantern demonstration of Photographs illustrative of Nervous Diseases, both from the Clinical and Pathological Aspect. The cases shown comprised—(1) cerebral diseases; (2) diseases of the spinal cord; and (3) peripheral neuritis. In the course of his remarks Dr. Reynolds said that early cases of disseminated sclerosis were sometimes diagnosed as hysteria and that cases of hysteria in which ankle clonus could be obtained should be carefully observed for further symptoms. The retropulsive gait in paralysis agitans had been said to be rare, but it was probably as common a symptom as the propulsive if duly looked for. It was not the case that in locomotor ataxia the heel left the ground last in walking. The movements of the foot in relation to the ground were the same as in ordinary walking. This was proved by an instantaneous photograph. It was doubtful whether alcohol alone ever caused peripheral

neuritis.—Dr. Reynolds was awarded a hearty vote of thanks by the society for his instructive demonstration.

**WIGAN MEDICAL SOCIETY.**—A meeting of this society was held on Dec. 5th, Mr. W. Latham, the President, being in the chair.—Dr. F. Rees contributed a paper on Epidemic Jaundice, detailing a number of cases, and he was followed by Dr. J. Blair who gave the clinical history of several cases which he had seen in his own practice.—A very interesting discussion took place in which the following members took part: The President, Mr. H. E. Jones, Mr. T. M. Angior, Mr. C. M. Brady, Mr. Holmes, Mr. Benson, Dr. R. P. White, Dr. Boyd, and the honorary secretary.—A vote of thanks was accorded to Dr. Rees and Dr. Blair.—Mr. M. G. McElligott showed a case of Enlarged Spleen in a man 30 years of age.

**FOLKESTONE MEDICAL SOCIETY.**—A meeting of this society was held on Nov. 29th, Dr. W. J. Tyson, the President, being in the chair.—Mr. H. Braund was unanimously elected a member.—Mr. M. G. Yunge-Bateman opened a discussion on the Notification of Tuberculosis.—The following also took part: Dr. T. Eastes, Dr. C. E. Perry, Dr. C. Latter, Dr. A. Gordon Wilson, Mr. M. Dobbs, Dr. P. G. Lewis, Mr. W. P. Barrett, Mr. W. F. Chambers, Mr. W. W. Linington, and the President.—Dr. Latter proposed "that a hearty vote of thanks be given to Mr. Yunge-Bateman."—This was seconded by Dr. Eastes and carried unanimously.

## Reviews and Notices of Books.

*Zoology: An Elementary Text-Book.* By A. E. SHIPLEY, M.A., and E. W. MACBRIDE, M.A., D.Sc. Cambridge: University Press. 1901. 8vo. Pp. xxi. 632, with 349 Figures in the text. Price 10s. 6d.

THE intending student of zoology has not much difficulty nowadays in finding a text-book to initiate him into the science. His difficulty, indeed, is in selecting from among a crowd so large that the choice becomes a little bewildering without some guidance. In the course of the following remarks we shall endeavour to indicate some of the features of this, the newest, text-book of elementary zoology for the guidance of the perplexed beginner. Good paper, clear type, abundant illustrations, and general attractiveness are superficial merits but none the less real. We well remember some of the dingy and depressing manuals which were placed before us for instruction in the "seventies"; at that time the translation of Gegenbaur came as a revelation of what trivial accessories could do to render the contained matter inspiring. But the practice of producing text-books of superior get-up is now so general that the matter requires no prolonged comment. One feature which impresses the reader in a preliminary turning over of the leaves of the handbook of Mr. Shipley and Professor MacBride is the prevalence of new illustrations, especially among the vertebrata; a number of these have been, it is to be presumed, drawn from specimens in the Cambridge Museum.

The method followed by the authors is to commence at the root of the tree of life and to work upwards. Now many distinguished authorities hold that in treating of animal structure it is desirable to commence with the higher forms and gradually to work down to the lower forms. In favour of this is the fairly certain fact that some notion, however rough, of human anatomy is possessed by most persons, whereas the very methods by which the lower animals are studied are new to the beginner. There is, however, no transition between the dissection of a frog with a scalpel and scissors and the examination of an amoeba with a microscope. The plunge into an unfamiliar subject must be made some time, and why not at the very outset? Besides, to begin with the low forms and to work upwards to the higher forms in an ascending order has the undoubted advantage of presenting the facts in logical sequence. We agree with the authors in adopting this plan, though they depart from it by placing the non-coelomate worms at the

very end of the book after the mammals themselves. As, however, the coelom is made the keystone of the animal edifice their behaviour in this respect is justifiable.

An introductory chapter deals with various prolegomena, such as protoplasm, the differences between animals and plants, and classification. Not without point, on the assumption that the reader will be a beginner, is the observation that it is rash to try to interpret the actions of beasts by motives and emotions like those which cause the sometimes apparently similar actions of human beings. The hyena and the Australian kingfisher at the Zoological Gardens frequently laugh loudly and long, but we need not assume that this is due to joy any more than we are compelled to put down to an expression of mingled misery and anger the occasional snarls of a wild cat in the same institution. But after this preliminary caution the authors have little to say about the psychological side of zoology. The work is, in fact, almost purely anatomical and the structure of a chosen type is explained in detail followed by a survey of the group to which it belongs. Added to this it should be noted that in order to avoid repetition the authors treat in a more lengthy fashion the animals which stand at the beginning of the series; certain generalities are there explained which need not be subsequently referred to. There is thus in this book a greater mass of matter than might be inferred from its actual length, considerable though that, after all, is. Two such experienced investigators and teachers as are Mr. Shipley and Professor MacBride would be hardly likely to cause criticism by actual errors of fact. We do not find much to correct in this respect, though the complete elimination of even the most elementary errors, even by persons well acquainted with their subject, is, as we have ourselves found and as the late Professor Milnes Marshall observed, "curiously difficult." The authors should, however, in a subsequent edition revise the account of the bird's syrinx at p. 492, as from their statement it might be inferred that in all birds the *membrana tympaniformis externa* is present; it is, of course, absent in most of the storks and in some other birds. It is, indeed, rather with interpretations of facts that we occasionally disagree with the authors. For example, when they say (p. 27) that a mass of protoplasm divided into units each with its nucleus would not be a protozoon we would refer them to such forms as *volvox*. It seems, also, a little difficult to grasp what they mean in writing (p. 32) that the extinction of protozoa which do not conjugate, but only reproduce by fission, "is the nearest approach to natural death which is met with among the protozoa." What on earth—or rather out of it—is it but death? These points, however, do not greatly detract from the usefulness of this really meritorious text-book.

*Epilepsy and other Chronic Convulsive Diseases.* By Sir WILLIAM GOWERS, M.D., F.R.C.P. Lond., F.R.S. Second edition. London: J. and A. Churchill. 1901. Pp. 320.

It is just 20 years since the first edition of this truly classical work was published. It has been long out of print and very difficult to obtain. We welcome a second edition, and while we note how well and completely it has been brought up to date it is a high compliment to the excellence of the first edition to remark that in spite of the fact that the deductions now tabulated are from a much more extensive series of cases than were those of the first edition—viz., 3000 cases as contrasted with the earlier series of 1450—it is astonishing to what a small extent the results arrived at in the first series of cases have been modified by the larger number now included. As has just been said, it is an indication of the high value to be attached to the earlier book that such is the case. It is scarcely necessary to enumerate the salient features of the book, the titles of the different chapters are a sufficient index. The first deals broadly with epilepsy in relation to its various

causes, predisposing and exciting; the second, third, and fourth with the symptoms, set forth in rich and varied detail; the fifth with organic epilepsy; the sixth with hysteroid convulsions and hystero-epilepsy; the seventh with what may be called the clinical pathology of epileptics; the eighth with the course of the disease; the ninth with pathology; and then follow in order chapters on the diagnosis, prognosis, and treatment of the disease. It need only be said that the work is a complete monograph on the subject and that all the latest advances both in the investigation of its pathology and treatment are set forth in great detail and with admirable lucidity. Students of Dr. Hughlings Jackson's evolutionary doctrines may perhaps be a little disappointed to find their master's views not quite so freely set forth as they might have wished, but those views have received recognition and, in regard to many points, cordial appreciation and adoption.

All who are interested, either for theoretical or practical reasons, in the fascinating subject of epilepsy, will heartily welcome this volume—a marvel of industrious and illuminating research—and will cordially congratulate the author on a piece of work which places his profession—for which he has done so much—under a still deeper debt of gratitude to him.

*Pharmacopœia.* By EDMUND WHITE, B.Sc. Lond., F.I.C., Pharmacist to St. Thomas's Hospital, London; and JOHN HUMPHREY, London: Henry Kimpton. 1901. One vol., crown quarto. Pp. 600. Illustrated. Price 14s. net.

THE word which forms the title of this excellent work is derived from the Greek *φάρμακον* and *παιδεία*, and the meaning is simply "information about medicines." The book is one for the pharmaceutical chemist rather than for the medical man. It is a work designed as a companion to the "Pharmacopœia Britannica" and should be read side by side with it. The work is carefully done, and the book may well be considered indispensable to the well-educated chemist. In a comprehensive and lucid manner the authors deal with the chemistry, the botany, the pharmacognosy, and the pharmacy of the drugs of the "British Pharmacopœia," and their work differs from that of many other writers on such subjects in being of good literary style.

The galenical preparations of the "Pharmacopœia" are described, each in its appropriate pharmacological place. There are copious illustrations of crude drugs, and the 46 plates devoted to them are beautifully executed. As far as we know no book of the kind has been previously published, and it may be therefore truthfully stated that the book meets a "distinct want." It might be supposed that in a volume written by authors who have been dispensing medicines for many years there would be a great deal of verbiage on the subject of methods to be adopted in the laboratory. Every teaching pharmacist no doubt has his own whims and fancies, if we may so term them. The critical faculty is exceedingly difficult to suppress, and laboratory methods certainly form a subject which might run away with anyone who knows his pharmacy well. In point of fact, such chapters on pharmacy as we have read are remarkable for their conciseness and practical utility. The book is one which all students may read without boredom and with much satisfaction. The "Pharmacopœia" and this companion, the "Pharmacopœia," are essentially guides for the dispenser, for their standards are fixed to meet the requirements of practical men in the dispensing trade and not of manufacturers on the large scale. We may add that the "Pharmacopœia" is well bound in red cloth, gilt and with marbled edges, and that we consider its price moderate.

#### LIBRARY TABLE.

*Experimental Hygiene.* By A. T. SIMMONS, B.Sc. Lond., and E. STENHOUSE, B.Sc. Lond. London: Macmillan and

Co. 1901. Pp. 322. Price 2s. 6d.—The Board of Education, in the syllabus recently issued for the examination in domestic science, requires a course of study embracing both physics and chemistry, but although there are already in existence many text-books dealing with these combined branches of science the majority of these have been written more especially for the use of medical students. The authors in the present instance have evidently endeavoured to produce a treatise that should impart the knowledge in as simple a manner as possible, whilst containing all the subject matter required by the syllabus referred to. By a practical application of the physical and chemical reactions described to the facts of everyday household management they appeal at once to the girl-student, for whom the book is primarily intended. The diagrams are numerous, and being, as a rule, original and well drawn, they form a very useful addition to the text. A few chapters devoted to the human body, digestion, and the chief constituents of such substances as flour, nitrogenous foods, fats and soaps are included, and here again the information given is clear and concise. The final section contains a brief account of micro-organisms and their work, with hints on the preservation of food, the necessity for cleanliness, and the prevention of contagion. The book throughout is well provided with descriptions of experiments, and these being of a simple and attractive character should encourage in the young student the faculty of observation and tend to impress essential facts on the memory. The authors may be congratulated on the production of a book that is suitable for the purpose for which it is intended.

*A Topographical Atlas of the Spinal Cord.* By ALEXANDER BRUCE, M.D., F.R.C.P. Edin., F.R.S.E. London: Williams and Norgate. 1901. 32 Plates.—The aim of the author in this work has been to set out in a pictorial manner the features of sections at each level of the spinal cord in such a manner as to facilitate the identification of the level of any particular section. It is thus a work which appeals more particularly to the specialist, and like all such works it is apt to miss the wider appreciation to which it is in every way entitled. No one who has not attempted such work can properly appreciate the industry and skill and artistic excellence which have been given to the work, and the author is to be congratulated on having produced a book which will be used daily in each neurological laboratory, and, we venture to think, will be most cordially appreciated. The plates are marvels of photogravure, as the sections must have been examples of great manipulative skill, and no praise is too great for the care which the author has taken to render the work in every way accurate and complete.

*Whitaker's Almanack, 1902.* By JOSEPH WHITAKER, F.S.A. London: 12, Warwick-lane. Pp. 776+143. Price 2s. 6d.—“Whitaker” is now in its thirty-fourth year, and every annual issue makes it more than ever a necessary book of reference for all British citizens. There is more good reading in “Whitaker” than in many rows of portlier tomes, and what Whitaker “doesn't know isn't knowledge,” as the late Professor Jowett, in the familiar rhyme, is made to say about the scope of his own information. The almanack has this year been entirely reset from new type, and we understand from the preface that owing to the large increase that has taken place annually in the circulation the book will in future be printed from specially prepared plates. In addition to the usual changes, the Accession of King Edward VII. and the honours bestowed for services in the war have revolutionised the orders of knighthood, the increases in Companions alone being: C.B., from 639 to 741; C.M.G., from 385 to 672; D.S.O., from 345 to 1312; and C.V.O. and M.V.O., from 53 to 162. These additions have necessitated shortening of certain of the special articles, but they are quite as effective and interesting in their present four-page form as they were formerly under the guise of from 10- to 20-page articles. Other of the special articles which have

from year to year been a feature of the book no longer make an appearance, but there is an admirable index of all articles which have been published in former issues. Monotonous praise is all we have to offer for a production which day by day and year by year saves our all too scanty time.

#### JOURNALS AND MAGAZINES.

*The Journal of Comparative Pathology and Therapeutics.* Edited by J. MCFADYEAN, M.B., B.Sc. Edin., F.R.S.E. Vol. XIV. Part III., September, 1901. Edinburgh and London: W. & A. K. Johnston, Limited.—The September quarterly number of this journal fully maintains the high standard which we are now accustomed to expect, though it is made up principally of reprints of papers that were read at the British Congress on Tuberculosis and have appeared elsewhere. These include Professor Koch's general address on the Combating of Tuberculosis in the Light of the Experience that has been gained in the Combating of Other Infectious Diseases; Principal McFadyean's address on Tubercle Bacilli in Cows' Milk as a possible Source of Tuberculous Disease in Man; Some Experiments on the Temperature necessary for Killing Tubercle Bacilli in Milk, by Professor Bang of Copenhagen; and How Can the Tuberculin Test be Utilised for the Stamping-out of Bovine Tuberculosis? by Professor Delépine. An original article by Principal McFadyean on the Bacteriological Examination of the Lesions in a Series of Horses that had Reacted to Mallein is of considerable interest, as he comes to the conclusion that his experiments, 26 in number, furnish no evidence at all regarding the curative effect of mallein. He finds that although some of the horses had apparently recovered 14 were proved not to have recovered, and, as he points out in the case of the former, it is quite possible that the course of the disease would have been the same if they had never been tested. He, moreover, shows that in some cases glands bacilli were recovered from the lesions in several animals that had apparently failed to react to some of the later tests, and he insists that when a horse reacts distinctly to the first test non-reaction to subsequent tests repeated at monthly intervals cannot safely be accepted as evidence of complete recovery. Reports of three clinical cases and class lists complete this number.

*The Quarterly Journal of Microscopical Science.* Edited by E. RAY LANKESTER, F.R.S., with the coöperation of ADAM SEDGWICK, F.R.S., W. F. R. WELDON, F.R.S., and SYDNEY J. HICKSON, F.R.S., with lithographic plates and engravings on wood. London: J. and A. Churchill. 1901. Vol. xlv., part 2. Price 10s.—This part contains the following articles: 1. The Lateral Sensory Canals, the Eye Muscles, and the Peripheral Distribution of certain of the Cranial Nerves of *Mustelus Lævis*, by Edward Phelps Allis, jun., with three plates. The article is a long and carefully drawn up description of the ophthalmic nerves in many kinds of fish, and the author criticises the views of other writers. He considers that there are in fishes several ophthalmic nerves between which it is necessary to make careful distinctions. He compares each of these with its homologue in the higher animals. The plates illustrating the text are interesting and instructive. 2. The Anatomy of *Scalibregma Inflatum*, by J. H. Ashworth, D.Sc., with three plates. *Scalibregma* is a polychæte worm varying from one-fifth of an inch to more than two inches long, one-fifth of an inch broad, and having about 60 segments. The morphology and anatomy of the animal are very fully described. 3. On the Pelvic Girdle and Fin of *Eusthenopteron*, by Edwin S. Goodrich, M.A. The *eusthenopteron* is a fossil fish, and the interest attaching to it is that of all the numerous extinct fishes usually included in the group *crossopterygii*, which includes the living *polypteridæ* and the fossil *diplopterus*, *cœlacanthus* and *holoptychius*, it is the first and only one in which the parts of the skeleton of the pelvic girdle and its fin have been found complete and in their natural relations.

# THE LANCET.

LONDON: SATURDAY, DECEMBER 14, 1901.

## The Report of the Departmental Committee on Food Preservatives.

AS we announced in THE LANCET of Nov. 30th, p. 1510, the report of the Departmental Committee appointed to inquire into the use of preservatives and colouring matters in food has at length been published. The committee discovered soon after their appointment that practically the question which they had to answer was: Are the substances at present in use for preserving or colouring foods or beverages so harmful to the health of the consumer as to call for prohibition, limitation, or declaration?—and to this question they have replied in very definite and, as we consider, reasonable terms. Nobody can doubt that the practice of putting preservatives in food is one which calls for control. We ourselves called loudly for such control some years before the committee were appointed, as we were receiving evidence day by day that the practice of adding preservatives was increasing and that no regard was paid to the choice of preservative or the quantity used. So strongly were we convinced that harm sooner or later would accrue, and that objectionable practices were likely to grow to an appalling extent, that we set on foot an inquiry with the result that public attention was forcibly drawn to the subject; and ultimately a Departmental Committee was appointed to consider the question and to place before the Government a definite pronouncement as to whether the practice demanded legislative interference—and if so how it could be applied without being vexatious to traders while at the same time protecting the health of the consumer.

Our view was that, certainly, in some instances the use of preservatives was legitimate so long as they were used in minimal quantity and that it could be shown that this minimal quantity, whilst sufficient to preserve the article of food in question, was harmless to the consumer. In a word, legislation whilst not encouraging the use of preservatives should specify the permissible substances for this purpose and should place limitations upon the amounts to be used. We are gratified to find that the recommendations of the committee, as now published, are almost exactly in accordance with this view. This accordance is all the more satisfactory to ourselves in view of the extraordinary care which the committee have evidently devoted to a consideration of the many points of view of the subject presented to them. They examined no less than 78 witnesses; they appointed sub-committees to inspect industrial processes at home and abroad; and the inquiry has lasted for just over two years.

We have had occasion more than once to complain of the

delay of the publication of the report, for several months ago we understood that it had been placed upon the table of the House of Commons. The delay was regrettable because legal proceedings in the meantime had been instituted in various parts of the country against those employing preservatives in food with the result that contentions similar to those which were being threshed out by the Departmental Committee took place in the courts with an inevitable waste of time and money. Of course, the recommendations have yet to be approved by Parliament before they can become a basis of actual legislation, but we are pretty certain that pending an Act regulating the use of preservatives magistrates will be guided by the conclusions of this committee. And we think that they will be correctly so guided, for the conclusions represent the only course that science and practice have dictated. It is true that much conflicting evidence has been furnished, but the committee, in our opinion, have abundantly cleared the issues in their recommendations.

Let us take, for example, the case of milk. The committee regard as idle the idea that it is impossible to supply London with milk not artificially preserved. And they had ample evidence on which to ground this opinion. One witness stated that for several years he had consigned milk to London—a distance of 126 miles—under a contract which prohibited him from the use of preservatives; the only precautions which he adopted, and which he regarded as indispensable, were carefully to strain the milk and to cool it by means of water, after which treatment there was never any trouble from the milk going sour. Again, one large dairy company stated that they used no preservative whatever in milk, and evidence was given by the Royal Agricultural Society that to their knowledge farmers were sending the milk of from 500 to 1500 cows daily to London from Faringdon and Didcot without the use of preservatives. Doubtless the absolute prohibition of adding chemical preservatives to milk would be attended with some inconvenience at first, but, as the committee remark, they were impressed with the need for facing this inconvenience and for rendering the vendors of milk containing preservatives subject to penalties under the Sale of Food and Drugs Act. Milk is *par excellence* the natural food, forming a very large proportion of the daily fare of the public, and this fact, coupled with its use by invalids and infants, abundantly justifies the recommendation (B) that the use of any preservative or colouring matter whatever in milk offered for sale in the United Kingdom should be constituted an offence under the Sale of Food and Drugs Act; and again, on similar lines of reasoning, is justified the recommendation (E) that in the case of all dietetic preparations intended for the use of invalids or infants chemical preservatives of all kinds should be prohibited. Readers of THE LANCET will probably remember our practical inquiry which related to the quality of the milk supplied to the metropolitan hospitals. Out of 11 samples of milk examined no less than four were preserved, one with formaldehyde and the rest with boron preservative. We note with satisfaction that at the instance of the committee samples of the milk supplied to the London hospitals were sent to the Government laboratory with the result that only one was found to contain a preservative. We are justified, therefore,

in concluding that the report of THE LANCET Special Analytical Commission on the Quality of the Milk Supplied to the Metropolitan Hospitals, which was published in THE LANCET of Jan. 1st, 1898 (p. 54), did undoubtedly good.

In the case of cream it is proposed to make the addition of boric acid or mixtures of boric acid and borax lawful, but the amount must not exceed 0.25 per cent. expressed as boric acid. In the same way it is proposed that the only preservative permitted to be used in butter and margarine shall be boric acid or mixtures of boric acid and borax, the proportions not to exceed 0.5 per cent. expressed as boric acid. The use of formaldehyde or any of its preparations is to be absolutely prohibited, and salicylic acid is not to be used in a greater proportion than one grain per pint in liquid food and one grain per pound in solid food, its presence in all cases to be declared. The use of copper salts in the so-called "greening" of preserved foods is to be prohibited. This, perhaps, is the most sweeping suggestion and we are not surprised to find a difference of opinion on this point. Dr. TUNNICLIFFE emphasises the importance of the appetising appearance of food which may be a factor in determining its nutritive value and in his opinion the gratification of the public taste for a perennial supply of green vegetables should not be arbitrarily prevented without very definite reason, whereby an industry which, if not important, is at least thriving, might be destroyed. It is well to remember, also, that in France an order was issued prohibiting the use of copper for the above purpose and that this order had subsequently to be rescinded. In Germany the actual enforcement of the prohibition is attended with difficulty, for preserved vegetables containing copper are easily obtainable on the open market in spite of it. But it must be admitted that it is highly undesirable that a poisonous substance should be used in food even to the smallest extent, and the position of those members of the committee who have condemned absolutely the use of copper salts in preserved food is very strong. They maintain that serious and widespread mischief may result from the consumption of food and drink containing even minimal quantities of poisonous metallic substances, as in the case of arsenic in beer, so that it is desirable that such poisonous substances should be rigorously excluded.

Finally, we are in complete accord with the opinion that the departmental machinery for controlling the preparation and conservation of food and drink in this country is not as complete as could be wished, and we agree that the appointment of a court of reference is indicated, embracing at least a chemist, a bacteriologist, a pharmacologist, a physician, a physiologist, and a representative of the public health service. Failing the creation of such a court the committee consider that the Local Government Board should possess, and should be called upon to exercise, such powers as will enable them to schedule by order any preservative or colouring matter which after such inquiry and experiments as the department may deem fit may be regarded as likely to prove dangerous to the public health. We have urged again and again the desirability of a control of this kind being exercised.

The report reflects credit upon all concerned. It contains the results of a most exhaustive and painstaking inquiry in

which the interests of the industries involved have been carefully studied, whilst the greatest regard has been paid to a much higher issue—the public health. We feel that the committee have adopted a very judicial and practically unassailable attitude.

## The William Smyth Memorial Fund.

As we have already announced, a fund is being raised for the widow and eight children of Mr. WILLIAM SMYTH who sacrificed his life to save the lives of others on the coast of Donegal during the outbreak of typhus fever on Arranmore Island. He fought the epidemic on the island while he could, and then, having resolved to convey his patients from the hovels in which they lay to the isolation hospital on the mainland, found that he would have to encounter not only passive but active resistance from the friends or neighbours of those who lay ill. Active assistance he obtained only from Mr. MCCARTHY, medical inspector under the Local Government Board, and these two brave and determined men rowed a crazy boat, the only one they could get, across to the island, and under police protection placed the patients in it. No fisherman would help them and a boat-load of police officers to whom they appealed to tow them to the mainland refused all aid. At last, tired out by their exertions, they brought the sick persons whom they had rescued to a landing-place, whence an ambulance conveyed them to the hospital, but Mr. SMYTH has since fallen a victim to the infection from which he sought to save others and has died.

Of the honour which brave acts done for others' sake ever win among men Mr. MCCARTHY has earned his full share, and what he did will not, we hope, be forgotten; but we are concerned now with the welfare of the widow and children left behind by Mr. SMYTH. He, it will be remembered, bore the full brunt of the struggle. If he ever knew that he had accomplished the work that he set himself to do, he died without thought of the praise his deed would earn for his memory, but only with the consciousness that he was leaving those he loved to face the world before he had had time to make provision for them. In such cases as his, we may truly say, the act is performed as a matter of duty, with full knowledge of the risks involved, and is rarely heard of in the outer world unless a tragic termination or some chance incident calls public attention to it. It is none the less incumbent on us to recognise bravery and devotion to duty when they are brought to our notice and when the best method of recognition is simple and obvious.

The fund to which we call attention has been inaugurated by donations from the Presidents of the Royal College of Physicians of Ireland and the Royal College of Surgeons in Ireland, while letters of sympathy, accompanied by subscriptions, have been received from the Lord Lieutenant of Ireland, from the Duke of ABERCORN, Lord Lieutenant of the county of Donegal, and from Cardinal LOGUE, Archbishop of the Roman Catholic Church in Ireland. It is a fund, however, to which all may well be invited to contribute, whether their donations be large or small and whether they are given by those who sympathise with the fate of a brother member of the same

great profession or by those who only look on at the work done by the medical practitioner and realise in some measure the dangers which he encounters in his life's routine. Mr. SMYTH, we need hardly say, went beyond the beaten track in which the physician may at any time meet with, and succumb to, a deadly disease. He sought his patients where he could hope for no adequate reward and he imposed on himself in his endeavour to rescue them a task which he might have avoided without discredit—a task, moreover, which was well calculated to exhaust him and to enhance the danger of infection and its consequences.

Sometimes honour falls to such a man as he was in his lifetime. Members of the medical profession have lived to receive the reward of bravery, not only when, as recently in South Africa, they have gained distinctions by their self-sacrificing devotion on the battlefield and in hospitals crowded with the victims of a great war, but also when in the more peaceful pursuit of their practices they have performed actions which have been made known. Nevertheless, the greater number of the acts of courage and self-sacrifice that are performed by members of the medical profession must of necessity be done without expectation of fame and without hope of reward, save only of the reward which is found in the consciousness of good work done. Mr. SMYTH has not survived to enjoy even this, but it will be possible for those who live in the neighbourhood in which he worked and died, to do something to help those whom he left behind, knowing well that nothing can repair the loss which they have sustained. Those beyond that neighbourhood, whose attention we more particularly call to the fund that has been instituted, will contribute in gratitude for the good example set and in memory of a true medical hero.

### The Election of Direct Representatives on the General Medical Council.

MR. GEORGE JACKSON and Mr. GEORGE BROWN have been elected Direct Representatives of the medical profession for England and Wales upon the General Medical Council—a result that had been very generally anticipated. Mr. GEORGE JACKSON, who is a new member, was "runner-up" at the last election, being defeated by Dr. J. G. GLOVER, whose vacancy, upon retirement, he now fills; while Mr. GEORGE BROWN has been re-elected for a second term of five years. We trust that these two gentlemen will endeavour efficiently to discharge the responsible duties that rest upon their shoulders. What is wanted, if the Direct Representatives are to be of sensible use to our profession, is united action; separate attempts to impress upon us that we have in our Direct Representatives stern and uncompromising reformers do not advance the general cause to an appreciable extent. Some difficulty about united action may have been created by the attitude of Mr. VICTOR HORSLEY who threw the whole of his influence upon Dr. S. WOODCOCK'S side in the recent election, attending meetings in that gentleman's behalf, and making vigorous and interesting, if not always judicious, speeches in his support. Mr. HORSLEY'S efforts have proved

unsuccessful; while both Mr. JACKSON and Mr. BROWN, who stood for election on the same ticket, take their seats upon the Council with the feeling that the third Direct Representative for England and Wales opposed their return to the best of his ability. He wanted the seat of one of them for Dr. WOODCOCK. We trust that Mr. JACKSON and Mr. BROWN, having been victorious, will also be magnanimous. They must forget that they have recently had in Mr. HORSLEY a conscientious opponent at the hustings, and must remember that he is a brother reformer with whom it is absolutely necessary that they should coöperate cordially if their separate or united services are to be worth their full value to the constituency. The candidature of Dr. C. W. HAYWARD, who occupies the bottom place in the poll, introduces a new element into the election of Direct Representatives. He is, we understand, a homœopathic practitioner, so that his election would have been tantamount to a recognition by the medical profession that the imaginings of HAHNEMANN are legitimate scientific developments. Dr. HAYWARD'S success was never in question, but the position would have been comic, although most serious, had the General Council of Medical Education and Registration found in its body a gentleman whose convictions compelled him to view much of the accepted theory of medical science as incorrect. There are many directions in which reform is admittedly required in the medical profession—directions which we believe Dr. HAYWARD to realise every whit as fully as the other candidates—but the educational curriculum of the student does not need to include instruction in therapeutic heresy.

### Annotations.

"Ne quid nimis."

#### UNEXPECTED DEATH WITHOUT OBVIOUS CAUSE.

INQUESTS are occasionally held in which the medical men who give evidence declare that they can assign no reason for the death, the post-mortem examination disclosing nothing to enlighten them. It is, of course, presumed that an analysis for poisons has been made, including a search for those that leave but little trace behind. It is well known, however, that cases do occur from time to time in which it is very difficult, if not impossible, to state what has been the cause of death. Some cases of this nature which have been recorded would probably have been explained if a more minute examination had been made. For instance, at an inquest held on the body of a child the medical practitioner who made the necropsy stated that he had made a careful examination of all the organs of the body (including the brain) but failed to find any morbid condition save slight congestion of the lungs. The coroner asked him whether he had examined the pharynx and larynx. The witness confessed that he had not, and on further examination a mass of bread was found occluding the opening into the larynx. The cause of death in those persons in whose bodies the most careful examination failed to detect disease has been assumed to be profound depression of the heart's action through nervous influences. Fright has frequently been known to cause death, or a blow on the epigastrium has brought about a fatal termination without leaving any

trace of injury either internal or external. In another class of case latent or undetected disease may be the cause of the cardiac failure. A patient may have suffered from an attack of diphtheria which had not been recognised, and during convalescence may die from syncope, in which case the true cause of death may be entirely overlooked. Still another series of cases is drawn attention to by Dr. Dixon Mann.<sup>1</sup> He there states that the bladder, urethra, and genitals are comprised among those parts of the body the abrupt handling or compression of which is attended with exceptional risk of sudden death from cardiac inhibition.

#### KENDAL AND ITS MEDICAL OFFICER OF HEALTH.

KENDAL has a town council and also a Health Committee appointed by that body. The chairman of the Health Committee is Councillor J. H. Braithwaite, and at a meeting of the town council held on Nov. 26th the Health Committee reported among other matters that the ambulance should be under the charge of the inspector of nuisances and that it should not be removed without his knowledge. We may as well say at once that this recommendation was after some discussion sent back to the Health Committee for further consideration. During the discussion, however, some curious statements were made. Mr. R. M. Craven, who is the medical officer of health and who was present at the meeting of the Health Committee when this recommendation was passed, wrote a letter to the town council mentioning that certificates of infectious disease were sent to him as medical officer of health and asking whether on receipt of a notification of a case of infectious disease he was at liberty forthwith to order the ambulance to convey the patient to the sanatorium, should he consider such removal necessary, or must he first obtain the consent of the inspector of nuisances to the use of the ambulance for such purposes. The mayor said that he supposed that the letter would have to be referred to the Health Committee but that in the meantime he would like to hear any comments which the chairman of that committee might like to make. Whereupon Mr. Councillor Braithwaite got up and characterised Mr. Craven's letter as "a piece of gross impertinence. It was nothing more or less than an attempt to go behind and to override the instructions of the Health Committee. It was one of those efforts of which they saw many before to assume an arrogant assumption of independent authority and action which had in times past caused so much difficulty, discomfort, and inconvenience in the whole of Mr. Craven's work with the corporation and its officers. It was a position of which he had already expressed an opinion, a position to which Mr. Craven had no right whatever, and one with which unfortunately, through his absolute lack of judgment, of tact, and of common sense, he was not even fit to be entrusted with ..... he was simply the servant of the corporation. .... In regard to the rural cases Mr. Craven had been in the habit of telegraphing and telephoning and ordering the ambulance about at all sorts of inconvenient and unnecessary times. .... There were many instances in which the unwarrantable and presumptuous interference of Mr. Craven must be stopped .....," and so on. "Mr. Craven must accept and obey." After these flowers of speech the orator sat down and was followed by Mr. Alderman Monkhouse who said that he thought Mr. Craven was perfectly right. He was right in calling attention to the matter, for there might be misunderstanding about the minute unless it was made more intelligible. Finally, as we have said, the minute was sent back. Mr. Craven has issued a special report wherein he states that, as a rule, the ambulance is ordered by the inspector

of nuisances and has only been ordered about 20 times by himself, generally on Sundays, bank holidays, and Saturdays. He gives instances to prove this. With regard to Mr. Braithwaite's lucubrations, we have not much to say, but, as a rule, people who are so ready to talk about impertinence and unwarrantable and presumptuous interference will generally be found to be in the wrong. Mr. Craven may be the servant of the corporation. We take it Mr. Braithwaite and the whole council are but the servants of the ratepayers. There is no disgrace in service—it is an honourable position, though Mr. Braithwaite evidently thinks otherwise. It seems to us that a simple way out of the difficulty would be to word the minute after an amendment which was proposed by Mr. Alderman Monkhouse but withdrawn, to the effect that the ambulance should not be removed without notice being given to the inspector or left at his office. As a rule, of course, it would be the inspector's duty to visit the house where the case of infectious disease was and to arrange for removal if this was considered necessary by the practitioner in attendance and the medical officer of health. But in emergencies, such as the case quoted by Mr. Craven, it is ridiculous to have a hard-and-fast rule the strict keeping of which might entail much danger, to say nothing of expense.

#### THE DRUCE CASE.

THE action by which Mrs. Druce, a widow, sought to disestablish the will of her late father-in-law, Mr. T. C. Druce, and to establish the story that he survived his death in 1864 and remained alive as the fifth Duke of Portland until a much later period, has been heard and concluded. The surviving executor of Mr. T. C. Druce was able to prove his will "in solemn form," bringing conclusive evidence that he duly made it and that he beyond all question died at the date alleged. The defendant was fortunate in being able to prove with such abundant clearness the death in 1864, which was the point upon which the whole of Mrs. Druce's case turned. Both Dr. Edmund Shaw and Mr. William Blasson, who so long ago were in partnership at Edgware and Mill Hill and attended the deceased, are alive, and their memory of a case, which must have been of some importance in the early career of two young practitioners, was perfectly clear. The deceased died from gangrene and erysipelas following operations rendered necessary by a succession of abscesses in the rectum and performed by the late Sir William (then Mr.) Fergusson. Dr. Shaw, who gave his evidence on commission, had particularly good reason to remember the occasion, as, in addition to the other circumstances, he himself contracted blood-poisoning in dressing his patient's wounds, as also did one of the nurses. Dr. Shaw also helped to carry out his own directions rendered necessary by the condition of the body, a condition which accounted for burial taking place without delay. These included the saturation of a sheet with chloride of lime, in preparing which Dr. Shaw was assisted by a nurse-housekeeper of the deceased. This lady also survives and she went into the witness-box and gave her own account of incidents no doubt indelibly impressed upon her memory. Mr. Blasson, Dr. Shaw's partner, who was present at the operations and saw the deceased at a time when his recovery was hopeless, gave evidence before the jury, while the nature of the facts which have encouraged Mrs. Druce in her persistent, and no doubt genuine, belief in the singular story which she has woven round her dead father-in-law is well exemplified in some of the questions which she put to Mr. Blasson in cross-examination. She dwelt, for example, with emphasis, as if it was a circumstance fraught with dire suspicion, on his having no books containing records of the case in question, receiving

<sup>1</sup> THE LANCET, June 26th, 1897, p. 1730.

naturally replies to the effect that he had no reason to keep books relating to his patients of nearly 40 years since in a practice at a place which he had quitted 10 years ago. Again she laid considerable stress upon the fact that the certificate of Mr. Druce's death did not bear the signature of Dr. Shaw, Mr. Blason, or any other medical man, asking whether in this respect it was not a unique document. The answer to this was given by another witness and by counsel, who pointed out that the signature of a medical practitioner who has attended the deceased has only been necessary since the Registration of Births and Deaths Act of 1874, so that in cases of registration at the period when Mr. Druce died no such signature is to be expected. We need not comment on the plaintiff's further allegation that one of the witnesses to Mr. T. C. Druce's will, then an elderly partner in a firm of solicitors, is not dead, but, having been for some years employed as a stoker in the underground labyrinths of Welbeck Abbey, is now keeping a lodging-house in London! It is certain that whatever defects may exist in our system of death registration, or existed in it before 1874, the decease of the late Mr. T. C. Druce has been proved with a singular conclusiveness that must be convincing to all but Mrs. Druce herself.

#### THE METROPOLITAN WATER-SUPPLY.

THE report on the condition of the metropolitan water-supply during the month of October has recently been issued by the Water Examiner appointed by the Local Government Board. The Thames water at Hampton, Molesey, and Sunbury was in good condition during the whole of the month. The height of the river varied from a point two inches above to one nine inches below the average summer level. The average daily supply derived from the Thames was 128,511,523 gallons, from the Lee 34,635,700 gallons, and from "springs" and wells 50,612,198 gallons. "Springs" and wells are mentioned in the report every month. There are springs at Hampstead and Highgate which to some extent supply the ponds the water of which is distributed by the New River Company for non-domestic purposes to the average daily amount of 68,839 gallons. These springs are obviously not included in the estimate of the water derived from "springs" and wells which is used for domestic purposes. We are certainly under the impression that the spring at Chadwell is the only one which at the present time yields water which is used by a metropolitan water company. More than one spring possibly opens into the Chadwell basin. The daily average amount of water used during the month was 213,828,330 gallons, which represents a daily average of 33.99 gallons per head for a population estimated at 6,290,974. The amount used per head daily during the month, except in the case of the customers of the West Middlesex Company, was less than that used in the corresponding month of last year. The total number of supplies furnished by the water companies during the month was estimated at 935,133 and this shows a daily average of 229 gallons for each such supply. The companies which are now credited with giving a constant supply to all their customers are the Chelsea, the East London, the Grand Junction, and the West Middlesex. The Lambeth Company do not profess to give constant service to more than 77.3 per cent. of their clients. A very slight improvement only has taken place in this respect during the last year. In October, 1900, the proportion of constant supplies was 75.6 per cent. The water rents which this company are allowed to charge are very high and the people who have the misfortune to live within the area of their supply are not well treated. The inconveniences attending an intermittent supply are well known and need not be here insisted upon, but the company give also other

grounds for complaint. During the month of October "the water of the Lambeth and East London Companies exhibited the deepest average tint of brown," or in popular parlance was the "dirtiest water." The Water Examiner also says that according to the statements of the chemists who report on behalf of the companies "the water of the Lambeth Company showed the highest average amount of organic carbon." The East London Company during the month obtained a supplementary supply from the Southwark and Vauxhall Company. The amount so obtained if spread over the whole of the month was equivalent to an average daily supply of 7,120,677 gallons. The Battersea station of the Southwark and Vauxhall Company is, of course, still in use. The results of a daily examination of the water distributed from Battersea might prove of interest. Dr. T. E. Thorpe, F.R.S., the analyst appointed by the Local Government Board, gives as a result of his examination of samples collected on Oct. 7th the information that as regards organic impurity the waters supplied should, judged from one single analysis of each, be placed in order of merit as follows: New River, Kent, Chelsea, Southwark, Grand Junction, Lambeth, West Middlesex, and East London. Dr. Thorpe speaks of the supplies given by the New River and by the East London companies as Lee-derived waters, and although the matter is not one of paramount importance it seems unnecessary to perpetuate an erroneous nomenclature. During the month of October considerably less than half of the water distributed by the East London Company was derived from the Lee. The amount obtained from the various sources gave the following daily average:—From the Lee and storage, 12,398,000 gallons; from the Thames, 16,058,000; from wells, 12,000,000; from Hanworth "springs," 1,595,000. The fact that the New River water is very largely derived from wells has been recently pointed out in THE LANCET. It does not appear from the report by whom the selection is made of the samples of water which are analysed by Dr. Thorpe. We do not remember to have seen an analysis of either (1) the water supplied from the East London Thames station during a period in which the river was in flood, or of (2) the water supplied from the Grand Junction Hampton station—that is to say, the local supply which is pumped directly to the neighbourhood.

#### THE CAUSATION OF CANCER.

IN THE LANCET of Dec. 7th (p. 1578) we published a paper entitled "Excess of Salt in the Diet a Probable Factor in the Causation of Cancer," by Dr. James Braithwaite. Dr. Braithwaite candidly admits that he has not produced absolutely conclusive proof of it, but merely offers the suggestion that salt is the essential factor in the etiology of cancer. His strongest argument is that malignant disease is unduly prevalent at Malton and Pickering, where the main articles of food would appear to be beef and bacon, a diet containing an excess of salt. An argument of this nature, however, would require considerable support before it would have any weight. A similar course of reasoning has been followed with regard to other conditions (e.g., anæmia) without success. The main point raised by Dr. Braithwaite, however, is that cancer is extremely rare amongst the Jews, and he offers the suggestion that this is to be explained by the fact that the Jews take less meat (beef) than the Gentiles and entirely refrain from bacon and ham, and consequently consume less salt. We believe, however, that a more systematic and widespread inquiry would show that cancer is not so uncommon amongst women and men of Jewish birth as has hitherto been supposed. Inquiries which we have ourselves made support this contention. Some years ago a similar view was held with regard to pulmonary tuberculosis, but all physicians attached to the special chest

hospitals, especially these in the East-end of London, would be able to bear witness to having met with many cases of that disease in the numerous Jewish patients attending the out-patient departments. Dr. Braithwaite's contention, however, may be of value as suggesting inquiries by other observers as to proof or otherwise of his theory. In a letter which we publish in another column Dr. Tucker Wise makes statements supporting Dr. Braithwaite's theory.

#### OBJECTIONABLE ADVERTISEMENTS.

WE called attention in an annotation last week to certain disgusting advertisements appearing in *Leach's Family Dressmaker* and *Leach's Children's and Young Ladies' Dressmaker*. In doing so we pointed out that respectable firms should not allow their advertisements to appear in juxtaposition to filthy invitations to buy vaginal douches, contraceptive powders, rubber preventives, and emollients specially prepared for the anointment of the same. We are glad to learn that Messrs. Allen and Hanbury immediately withdrew their advertisement from *Leach's Children's and Young Ladies' Dressmaker*. This is exactly the course we should have expected from a firm of their high position, and we trust that their action will lead to imitators. Whenever a firm of repute and position finds that advertisement columns which they use are being prostituted the firm should withdraw its support from the paper. In this way the fact will be brought home to editors and proprietors of newspapers who are careless of public morality that dirty money gained means clean money lost. Then reform of the advertisement columns will follow. We commend the promptitude of Messrs. Allen and Hanbury to the notice of others.

#### AUTO-INTOXICATION AS A CAUSE OF GENERAL PARALYSIS.

DR. JOHN MACPHERSON, Commissioner in Lunacy for Scotland, contributes a brief critical article to the December number of the *Edinburgh Medical Journal* dealing with the subject of auto-intoxication as a cause of general paralysis, which opportunely indicates the present stage of the question. The thesis that syphilis precedes in the great majority of cases the appearance of symptoms of general paralysis is accepted as substantially correct and it is pointed out that the course of general paralysis itself is marked by the recurrence of febrile attacks "during which there is reason to believe that hyperleucocytosis occurs." The febrile reaction and the leucocytosis are regarded as pointing conclusively to a toxic infection of the system. The remittent character of the fever shows either that the toxin is regularly discharged from the system or that the body acquires periodical immunity from its influence. The occurrence of gastro-intestinal disturbances in the course of the disease is due to the fact that lesions are developing in the mucous membranes of the intestines such as have been pointed out by various observers. The view that these lesions are trophic and secondary to changes in the nervous system is regarded by Dr. Macpherson as being untenable. The symptoms of vaso-motor disturbance and sudden losses of nervous function which are characteristic of the early stages indicate also the probable action of a toxic agent, and there is every indication that such toxæmia arises from the alimentary canal and is, in fact, a form of auto-intoxication. Reference is made to the clinical observations of Dr. Lewis Bruce of Perth on general paralytics as regards the temperature changes and leucocytosis and to the occurrence of lesions (inflammatory and necrotic) in the mucous membranes of the intestines described by Dr. W. Ford Robertson of Edinburgh, and it is argued that a parallelism might be observed between auto-intoxication on the one hand and the fever and degree

of leucocytosis on the other. The auto-intoxication might be due to a virulent activity of the bacillus coli communis or other intestinal microbes the rôle of which demanded further investigation.

#### THE NOBEL PRIZES.

THE late Mr. Alfred Nobel, who, as is well known, was the inventor of dynamite and thereby realised a large fortune, bequeathed by his will certain sums of money to provide a fund out of which should be paid prizes to persons who might be considered most eminent in various branches of science or in the cause of peace. The award for 1901 was declared on Dec. 10th. The Peace prize, value 150,000 kronen, was divided equally between M. Henri Dunant and M. Frederic Passy. M. Dunant, as our readers may know, was the founder of the International Red Cross Society. Some years ago it was reported that he was in rather reduced circumstances, so that the sum awarded to him is not only a slight recognition of his labours for the good of his fellow-creatures but will help to make his declining days pass more pleasantly. Other prizes of the value of 200,000 kronen respectively were awarded to Dr. Emil Behring of Halle for medicine, mainly, we take it, on account of his work as regards diphtheria; to Professor Jakobus van't Hoff of Berlin, for chemistry, who is so well known for his researches into the process of solution; and to Professor Wilhelm Roentgen of Munich for physics. In literature M. Sully Prudhomme was adjudged the winner.

#### ARTERIO-SCLEROSIS AND BRAIN DISEASE.

AN important discussion on Arterio-sclerosis and Brain Disease, which took place at the recent annual meeting of the New York Medical Association held at the New York Academy of Medicine, is reported in the *Medical News* of Nov. 2nd, 1901. In introducing the discussion Dr. Charles E. Nammack of New York said that the causes of arterio-sclerosis were, in addition to the acute infectious diseases, certain chronic intoxications such as are produced by gout, lead-poisoning, alcohol, or syphilis. The initial period of the disease was marked by a contraction of the peripheral blood-vessels. Without this arterial degeneration did not develop. Over-feeding was a frequent cause of arterio-sclerosis, and worry and cerebral overstrain tended to premature sclerosis of the cerebral arteries. Physicians were especially prone to suffer from cerebral overstrain and arterio-sclerosis. The death-rate among practitioners in New York was only surpassed by that among saloon-keepers, butchers, quarrymen, and factory operatives. Medical men died particularly from three diseases connected with arterial degeneration—Bright's disease, cardiac disease, and cerebral apoplexy. Among the early symptoms of arterio-sclerosis were distress in the region of the heart, sudden disinclination for work, and headaches of sudden onset. Cessation from work, abstemious diet, giving up alcohol, and the adoption of quiet open-air occupation were the therapeutic indications. Dr. Delancey Rochester pointed out that the fibroid changes in the arteries obstructed the freedom of outflow of the blood, and the extra work thus thrown on the heart tended to bring about hypertrophy and fatty degeneration of the myocardium. The involvement of the coronary arteries led to attacks of angina pectoris. Epigastric pain was one of the early symptoms present in cases of arterio-sclerosis, and this led to the diagnosis of gastritis when the real condition was vascular degeneration. He preferred to use cactus and valerian in treatment, avoiding the use of digitalis, which was a dangerous drug in arterio-sclerosis. The diet must be carefully regulated and when heart-compensation was failing the patient must be put to bed. In the latter case the use of passive and resisted movements as employed by Schott at Nauheim

was of great importance and the best cardiac tonic was strychnine. Dr. E. Lefevre contended that the conditions that developed with cardio-vascular degeneration and renal cirrhosis were evidently to be classed together, the most important factor being a hereditary predisposition to early degeneration of the arteries. On the basis of predisposition chronic poisons, such as alcohol, lead, and syphilis operated as factors of exceptional potency.

#### MEDICAL APPOINTMENTS TO THE PRINCE OF WALES'S HOUSEHOLD.

His Royal Highness the Prince of Wales has been pleased to make the following medical appointments to His Royal Highness's Household:—Physicians-in-Ordinary: Sir William H. Broadbent, Bart., K.C.V.O., M.D.; Sir James Reid, Bart., K.C.V.O., K.C.B., M.D.; and Sir Francis H. Laking, K.C.V.O., M.D. Surgeons-in-Ordinary: Sir Frederick Treves, K.C.V.O., C.B., F.R.C.S., and Mr. Herbert W. Allingham, F.R.C.S. Honorary Physicians: Dr. Robert W. Burnet and Dr. Samuel J. Gee. Surgeon Apothecary to His Royal Highness's Household-in-Ordinary: Sir Francis H. Laking, K.C.V.O., M.D. Surgeon Apothecary to His Royal Highness the Prince of Wales and to the Household at Sandringham: Dr. Alan R. Manby, M.V.O. Chemist and Druggist: Mr. Peter Wyatt Squire.

#### THE FUNERAL OF SIR WILLIAM MACCORMAC.

THE funeral of the late Sir William Mac Cormac was held on Dec. 9th, the first part of the Office being sung at the Church of St. Peter, Vere-street, W., the Rev. Canon Page Roberts being the officiant. The body arrived at the church at 11 A.M. and the hearse containing it was followed by the mourning-coaches in which were Lady Mac Cormac, Miss Mac Cormac, Mr. Henry Mac Cormac, Mr. J. Mac Cormac, and the other chief mourners. At the church General Sir Andrew Clark represented the King, representatives of the French and German Embassies, with the French Consul-General being also present. The Royal College of Surgeons of England were represented by Mr. Henry G. Howse (President), Mr. Thomas Bryant, Mr. Henry T. Butlin, Mr. W. Watson Cheyne, Mr. Reginald Harrison, Mr. John Langton, and Mr. Alfred Willett, and Professor Charles Stewart, the Conservator of the Hunterian Museum, was also present. The Royal College of Physicians of London were represented by Sir William Selby Church (President), Sir Dyce Duckworth (treasurer), and Dr. Edward Liveing (registrar). Dr. Hector Mackenzie represented the physicians on the staff of St. Thomas's Hospital, and most of the surgeons on the staff were present, including Mr. Henry H. Clutton, Mr. Bernard Pitts, Mr. George Henry Makins, Mr. William Henry Battle, Mr. Charles A. Ballance, Mr. Francis C. Abbott, and Mr. Cuthbert S. Wallace, while the matron and the assistant matron represented the nursing staff. The French Hospital also sent a deputation, while the Army Medical Department was represented by Surgeon-General Henry Skey Muir, C.B. Various other institutions and departments were represented, such as the Navy Medical Service, the Italian Hospital, the University of London, the Irish Medical Schools and Graduates' Association, and the Leathersellers Company. The British Red Cross Society were represented by Lord Lister, Viscount Duncannon, and Viscount Knutsford. Among friends were Sir John Furley and Lady Furley, Sir William H. Broadbent, Sir Samuel Wilks, Sir John Williams, Mr. Walter Tyrrell, Mr. Alfred D. Fripp, and many others. A very large number of wreaths had been sent by various societies and friends. The first part of the Order for the Burial of the Dead having

been sung in the church, the body was replaced in the hearse and taken to Kensal Green for interment, where the prayers of committal were said by Canon Page Roberts. The coffin bore the inscription: "William Mac Cormac, born Jan. 17th, 1836; died Dec. 4th, 1901."

#### THE TUBE PROBLEM.

At a meeting at the Auctioneers' Institute on Dec. 4th Mr. S. M. Freeman, K.C., read a paper upon the Tube Problem, which possessed many points of interest to medical men, whether citizens of London or not. For electric underground traction is likely to play a part in urban development everywhere. Mr. Freeman pointed out that the legal position of freeholders within 100 yards of any line of tubes should be placed upon a more certain foundation than at present existed, also the right to compensation for damage to property by owners within the same area should be secured, whether from the construction or working of the line. His declaration that the assurances given that no possible damage would be caused by the construction of the Tube Railway had not been realised will be fully endorsed by most of the occupants of five miles of houses along the line of route. In the discussion which followed the usual references were made to the immunity from trouble enjoyed by the South London line. Without attempting to offer any opinion as to the cause of the vibration, which it is evident the able men responsible for the planning of the line were unable to foresee or avoid, we may venture the suggestion that the two lines are not comparable. In the case of the South London line, which we believe is laid much nearer to the surface than is the case with the Central London Railway, the waves of vibration would radiate to the surface within a very limited area, probably exceeded by the width of the roadway. Again, no comparison is possible between the damage to property caused in the construction of the two lines in view of great difference in the physical features of the districts through which they pass. As pointed out at some length in an article which we printed in our issue of May 12th, 1900, on the construction of the Central London Railway, the alteration in the level of the subsoil water following the course of the tube is one of the principal causes of all the damage done to property along its course. For this reason any line running east and west, as is the case with the Central London Railway, would cut across the natural drainage subsoil water flowing to the Thames—which a railway running north and south like the South London line would probably avoid. In the case of the Central London Railway it was maintained that no water could come externally in contact with the tube, but this, like some other rash statements made in connexion with the undertaking, is disproved by the liberal use of sawdust on some of the stairways and stations for the purpose of absorbing the water that soaks through. We are far from being oblivious to the great advantage that tube railways are likely to prove to the travelling public, but while matters are more or less in the experimental stage it would be disastrous if London were "rushed" by company promoters without very deliberate consideration on the part of the responsible authorities. The suggested scheme for shallow underground tramways proposed by the London County Council is free from many of the objections inseparable from lines laid at a great depth. The great advantage which the former possess of providing a chamber giving ready access to the maze of pipes, cables, and sewers with which every large town is provided and thereby obviating the necessity for opening the roadway to correct every small defect is one not to be lost sight of. It is also probable that the difficulty of vibration experienced in the case of the Central London Railway would in the case of light tramways be overcome, but of course this remains to be proved. From

a medical point of view this question of vibration is so important, the suffering to invalids and to persons confined to their houses being so real under the constant little jars and disturbances, that the medical profession may be depended upon, whenever a tube scheme is under consideration, to use their influence in compelling the promoters to take all possible precautions.

#### THE DISTRIBUTION OF PLAGUE.

A TELEGRAM from the Governor of the Cape of Good Hope received at the Colonial Office on Dec. 4th states that for the week ending Nov. 30th the cases of plague in the Cape Peninsula numbered 0. At Port Elizabeth the cases were as follows: Europeans, 1; coloured persons, 1; all other places, 0. There were no deaths from plague anywhere in the colony. The cases of plague in persons under naval and military control numbered 0. 5 cases of plague have been discovered at Mossel Bay during the week, but owing to absence of particulars of age and sex they have not been included in the above return. Of these 5 cases of plague 3 proved fatal. As regards Egypt, during the week ending Dec. 1st 2 cases of plague and 3 deaths from the disease have been reported throughout Egypt; these cases and deaths all occurred among natives at Zifteh. During the week ending Nov. 24th a man was found dead out of hospital at Zifteh, and on examination he was found to have died from pneumonic plague. A few days afterwards his wife, and subsequently his mother-in-law, were taken ill and eventually both died from pneumonic plague. These 2 women had nursed the man during his illness. As regards the Mauritius, a telegram from the Governor received at the Colonial Office on Dec. 6th states that for the week ending Dec. 5th there were 52 cases of plague, of which 37 were fatal.

#### CELEBRATION OF VIRCHOW'S BIRTHDAY IN BRAZIL.

PROFESSOR VIRCHOW'S eightieth birthday was celebrated with much enthusiasm in the important maritime city of Bahia in Brazil. In honour of the occasion a very numerous public meeting was held on Oct. 13th, the company present including the Governor of the State, the President of the Municipal Council, the German Consul, and the Director of the Schools of Medicine, Jurisprudence, and Engineering. The arrangements were made by the Gremio dos Internos dos Hospitais da Bahia, an association of the internes of the hospitals, and the meeting took place in the handsomely decorated hall of the Gremio Literario. M. Pontes, the president of the association, opened the proceedings with an address, after which the Governor of the State took the chair. Professor Juliano Moreira, speaking in the double capacity of a member of the medical profession and one of the editorial staff of the *Gazeta Medica* of Bahia, gave a comprehensive review of Professor Virchow's achievements, not only as a physician and a pathologist, but also as a biologist and as a *savant* whose methods of research had influenced every branch of human knowledge. He concluded by reading aloud a Latin address to Professor Virchow written on parchment for the purpose of being sent to him. M. Paranhos, speaking in the name of the *Revista do Gremio*, gave a sketch of the vast amount of work which Professor Virchow had contrived to crowd into the space of 60 years. Addresses were also delivered by M. Oscar Freire, representing the Gremio dos Internos, and by Dr. Egas Moniz, speaking in the name of the Gremio Literario and of a number of German journals of Paraná and Rio Grande do Sul. Poems in honour of Germany and Professor Virchow were recited by the last-named gentleman and by M. Damasceno Vietra, after which the national airs of Germany and Brazil were played by the band. The October issue of the *Gazeta Medica* of Bahia, the *doyen* of the medical press

of North Brazil, is entirely a "Virchow number," in which the life and work of the venerable *savant* are treated in six elaborate articles by Professor Juliano Moreira, Dr. Alfredo de Andrade, Professor Pacifico Pereira, Dr. Americo Fróes, Professor Matheus dos Santos, and Dr. Afranio Peixoto. The *Revista do Gremio dos Internos dos Hospitais* has also published a special Virchow number.

#### MEDICO-LEGAL SOCIETY.

At a meeting held at 20, Hanover-square, W., on Dec. 5th it was unanimously resolved to form a medico-legal society. Dr. F. J. Smith, who presided, explained how the meeting came to be held and the objects aimed at in proposing the society, which would, no doubt, be an advantage to medical men and lawyers by extending consideration to every question involving medical and legal matters. He also read letters from Dr. Harvey Littlejohn, Dr. Wynn Westcott, and others supporting the movement. On the motion of Dr. W. R. Smith, seconded by Dr. R. L. Guthrie, a committee was appointed to draw up a set of rules, to arrange for the next meeting, and to enlist members. Those who are willing to join the society are invited to send their names to Mr. McCallin, Reading Rooms, Inner Temple.

#### THE SMOKE NUISANCE.

As everyone knows, fogs are inevitable owing to climatic conditions, but London fog is rendered direful by the amount of smoke—i.e., the products of the imperfect combustion of coals—which it contains. The dirty portion of these fogs consists of soot and various tarry matters and the irritating portion of sulphuric and sulphurous acids. All these nuisances were well exemplified in the fog which hung over the Thames valley on Nov. 16th. The Public Health Acts only deal with black smoke emitted from chimneys other than those of private houses, and even when the owners of such chimneys are summoned the regrettable laxity of magistrates very often permits them to escape either scot-free or else upon payment of a most inadequate fine. However, the action of the Coal Smoke Abatement Society and perhaps our own oft-repeated protests have certainly done something to improve the conditions of factory chimneys. As we have said over and over again, no silly excuse with regard to the difficulty of getting Welsh coal should be allowed to weigh for one minute. It is quite easy to arrange a factory furnace so that it can burn bituminous coal and yet cause no foul smoke. Witness the case of Nottingham, where manufacturers found it better for their pockets that their chimneys should be smokeless. But the great offenders in the matter of emitting dirty smoke are undoubtedly the chimneys of private houses. We will not consider the question of stoves, for though they would undoubtedly cure the evil yet we confess, in company with most of our fellow-countrymen, to a general preference for an open grate. There are, however, two simple methods of having a smokeless fire—or rather a fire emitting clean smoke—in an open grate. The one is to burn coke and the other is to burn anthracite. At the recent Congress of the Royal Institute of Public Health held at Eastbourne Sir C. A. Cookson, K.C.M.G., read a most interesting paper entitled "A Smokeless London." In it he advocated very strongly the claims of one of the two methods which we have mentioned above. He has made a personal trial of burning either coke or anthracite in an ordinary grate during two successive winters and finds that by the simple expedient of having a Bunsen burner underneath the grate the fire can be easily and cheaply lighted or relighted even at the present price of gas. Such a fire is bright and cheerful. The only objection which we can see to the adoption of this method is that at present there is not enough of anthracite or of coke on the market to supply a general demand for either,

but probably this difficulty could be overcome. A beginning might be made with the domestic kitchen, and another point to which the direction of the London County Council might well be directed is the case of the numerous new houses and flats which are constantly arising. No grate of any kind should be allowed in them which is not constructed so as to burn either coke or anthracite. We do not ask the average householder to consider matters of health, for the average householder does not care two straws about anybody's health except his own, but we do ask him to consider how much he would save in paint and in bills for cleaning if the atmosphere in which he lived were more like that of a small Italian town instead of being like the fumes from Tophet. Sir Charles Cookson's suggestion seems to us to be practical and might well be tried.

#### THE WORKING OF THE INEBRIATES ACT.

AN important paper on the Working of the Inebriates Act is contributed by Mr. John Carswell of Glasgow to the October number of the *Journal of Mental Science*. The Inebriates Act as passed was an attempt on the part of the Legislature to provide for the control of persons who were, in Mr. Carswell's opinion, "adjudged to be criminal, who were yet not to be punished for crime but treated for disease." But the class of offences scheduled in the Act, four convictions for which might bring a person within the scope of the Act if he were also a habitual drunkard, limited its operation practically "to the street pest, drunken prostitute, and thief, and the drunken flotsam and jetsam of our towns." The expectations of the Government were high-pitched, especially as regards inebriety in Scotland, but the operation of the Act had not justified such expectations. Thus, in Glasgow the number of persons convicted three times and over for offences under the Act for the year ending June 30th, 1901, was: males, 41; females, 139; total, 180, of whom 26 were over 50 years of age. In London the number of similar convictions at the police-courts was: males, 161; females, 258; total 419. The London County Council and the Glasgow Corporation were, as far as Mr. Carswell knew, the only two municipal bodies which had directly undertaken the work of establishing and maintaining reformatory under the Act. The London County Council scheme comprised provision at Farmfield, near Horley (Surrey), for 33 females, provision for Roman Catholic women at St. Joseph's, Ashford (Middlesex), and an arrangement with Lady Henry Somerset for the reception of a few female inebriates at Duxhurst, Surrey. This last arrangement was about to cease, but the Council had in hand the erection of further buildings at Horley for 80 female patients to replace the present accommodation. The number of persons under the care of the London County Council in July, 1901, was 108, all females, and at Brentry Homes, Bristol, there were 25 males and 125 females, making a total for England of 258. These, with a few additional patients in Duxhurst and a few who had been under care and discharged, brought up the total for England to nearly 300 persons committed under the Act, almost all females. In the Glasgow Corporation home there were 16 female patients. These figures referred only to persons committed under the Act, and took no account of voluntary residents in retreats or other institutions. A State reformatory had been set up in Scotland, but so far there had been no committals. Of the 16 female patients at the Glasgow home all had been more than once in prison and nearly all in poor-houses. They had all lived loose lives, many of them were prostitutes, and several had had syphilis. "With perhaps two exceptions out of the 16 they were all living loose, degraded, idle, and abandoned lives, and drunkenness only played a part in the general degradation." Such patients had not only to be cured of their degraded habits but would have to be placed on their discharge in

fresh social surroundings to expect any good results—a very difficult matter to accomplish. Habitual criminals, vagrants, and prostitutes were generally of intemperate habits, and these were the persons who fell most readily into the meshes of the Act. There was a widespread disappointment that the Act did not deal with the non-criminal and non-vagrant inebriate—the class that called most urgently for treatment. A satisfactory Inebriates Act ought to embrace provision for three distinct classes of persons who were sources of danger and expense to society—viz., first, vagrants, paupers, and prostitutes; secondly, inebriates convicted of offences but not belonging to the first-named class; and, thirdly, inebriates of the non-criminal class; and it was to be hoped that further legislation would follow.

#### THE SITUATION AT THE MACCLESFIELD INFIRMARY.

THE honorary consulting physicians and surgeons of the Macclesfield Infirmary having met the governors of the institution at a private conference upon the situation have supported their professional colleagues, and as a result, the governors have decided to fall in, upon all essential points, with the views of their honorary medical staff; the junior house surgeon, however, who was elected by the governors in opposition to the wishes of the honorary medical staff, who did not consider that the post was one which a woman could fill either conveniently or adequately, has refused to resign her position. At a meeting of the governors held on Wednesday last the following resolution was passed:—

"That the honorary medical staff be asked to withdraw their resignations and that Miss Clarke be released from her promise to stay 12 months."

The resolution, as we read it, simply places the matter *in statu quo*, for the honorary medical staff certainly cannot give way.

#### "THE ADVANTAGES OF A TRACE OF ALBUMIN AND A FEW TUBE CASTS IN THE URINE OF CERTAIN MEN ABOVE 50 YEARS OF AGE."

UNDER this paradoxical title Professor William Osler has contributed a valuable article to the *New York Medical Journal* of Nov. 23rd. The successful business man, who lives intensely, strives hard for wealth, takes plenty of good food three times a day, with two or three glasses of spirits, and smokes from six to ten cigars, works in blissful ignorance that his bodily mechanism is in some respects similar to that of the steam-engine. His supply of "fuel" is out of proportion to the "energy" liberated. "Careless stoking" with high pressure for 25 years means early degenerations, and "the waste-pipes"—the kidneys—are often the first to show signs of ill-usage. He receives a rude shock when his insurance company declines to allow him to increase the amount of his life policy because of a "slight trace of albumin and a few tube casts in the urine." However, if at 50 he follows good advice, restricts his diet, gives up alcohol, and resigns his position on six or eight boards, the discovery of the albuminuria will be a great benefit. Professor Osler refers to the case of a distinguished public man in Canada in whose urine albumin and casts were accidentally discovered. He was nearly 60 years of age, lived a very active life, and was careless in eating and drinking. A consultation was held with the late Sir Andrew Clark who took a sombre view of the case. After a year's rest the patient resumed work. He is now a vigorous nonagenarian. Professor Osler points out that in men in the fifth and sixth decades albuminuria is by no means infrequent and not always serious. It is probably the expression of pre-senile changes in the kidneys, the result of arterial degeneration (the "renal inadequacy" of Sir Andrew Clark). The albuminuria and the number

and variety of the casts are not of as much importance in prognosis as are other factors. The facts indicative of serious disease are: (1) persistent low specific gravity of the urine (1008 to 1012); (2) marked arterial sclerosis with the apex beat an inch or two outside the nipple line and a ringing accentuated aortic second sound; and (3) albuminuric retinitis. A trace of albuminuria and a few casts are the danger signals. Professor Osler quotes approvingly Aphorism 13 of George Cheyne's "Essay on Regimen." "Every wise man after 50 ought to begin to lessen at least the quantity of his aliment; and if he would continue free of great and dangerous distempers and preserve his senses and faculties to the last he ought every seven years to go on abating gradually and sensibly and at last descend out of life as he ascended into it, even into the child's diet." Very similar advice is given by Sir Henry Thompson in his work on diet, the second edition of which we recently reviewed,<sup>1</sup> and the author in his own person bears eloquent testimony to the value of moderation in diet.

#### SYMMETRICAL GANGRENE FOLLOWING PNEUMONIA.

At the meeting of the Société Médicale des Hôpitaux of Paris on Oct. 18th Dr. Henri Dufour described a case of this very rare complication of pneumonia. A woman, aged 58 years, had double pneumonia. Some days after recovery there was generalised polymorphous erythema. Then gangrenous patches appeared on the fingers, the toes, the tip of the nose, and the lobules of the ears. There was no precedent "local syncope or asphyxia," but almost from the first vesicles filled with turbid fluid appeared. Suppuration followed. The patient had much albuminuria and died from purulent infection. At no period did pulsation cease in the peripheral arteries. Bacteriological examination of the blood during life was negative. At the necropsy the lungs and heart were found to be healthy. There was pus in the left knee-joint. The peripheral nerves were found to be normal. Portions of the integument of the most affected finger—the left index—were removed and examined. The tissue was crowded with leucocytes. The arterioles of the preparation were not obliterated, but the venules were in a state of phlebitis. Dr. Dufour's explanation of the gangrene is that it resulted from the action of toxins on the cells of the peripheral parts, which were the most vulnerable in consequence of the circulatory difficulty at the greatest distance from the heart. Whenever the circulation is embarrassed the extremities are in danger of gangrene, as is shown by the cases of pericarditis reported by M. Widal in which "local asphyxia" occurred. The vulnerability of the most peripheral parts has been shown experimentally by M. Phisalix. On placing a microbial culture contained in a collodion capsule in the peritoneal cavity of a guinea-pig he found that symmetrical gangrene of the extremities (including the nose and ears) was produced. In the discussion which followed M. Widal pointed out that symmetrical gangrene of the extremities might occur independently of Raynaud's disease and might result from various pathological states. He referred to a case which he reported at the last International Medical Congress in which symmetrical gangrene followed suppurative pericarditis with great effusion. This point requires to be emphasised, for some English writers seem to regard the term "symmetrical gangrene" as synonymous with "Raynaud's disease." Now Raynaud's disease is essentially a vaso-motor affection of persons whose peripheral circulation is unduly susceptible to cold. In its typical form the fingers and other peripheral parts become first pale (local syncope) and then blue (local asphyxia), and in severe cases gangrene may follow. Symmetrical gangrene is thus simply a result of Raynaud's disease. But as

in the cases of Dr. Dufour and M. Widal related above symmetrical gangrene may occur quite independently of Raynaud's disease.

#### SMALL-POX IN LONDON.

THE latest returns show a decrease in the number of cases of small-pox as compared with those of last week. Thus on Saturday, Dec. 7th, there were 19 fresh cases notified and removed; on Sunday, Dec. 8th, the number was 11; on Monday, Dec. 9th, there were 18 fresh cases; on Tuesday, Dec. 10th, there were 9 fresh cases; and on Wednesday, Dec. 11th, there were 15 fresh cases.

#### RATS AND PLAGUE.

THE decision of the Turkish Government to require a "certificate of rat-destruction" before any vessel arriving at Constantinople from an infected port is allowed to discharge, as noted in the *Board of Trade Journal* of Nov. 21st, is a distinct advance in preventive medicine, and is rightly based, as Professor Koch has well pointed out that such measures should be, upon recently acquired knowledge as to the causation of the disease. Reliance upon certificates, however, is not to be absolute, and vessels from infected places, though permitted to operate in the port, are not allowed alongside the quays, while vessels not provided with certificates have to go to a lazaret to discharge, as "rat-destruction" can only be properly secured in an empty ship. The Order in Council for Western Australia of April 3rd is equally stringent. Section 10 prescribes that all rats on ships coming from any place or country where bubonic plague is known or suspected to exist shall be immediately destroyed; that all rats in every store, warehouse, or other building under the control of the railway, customs, and harbours department at the ports of the colony shall be destroyed; that complete precautions shall be taken to prevent rats coming ashore from any ship in any port of the colony; and that the local boards of health at all the ports and towns of the colony shall take the necessary steps to have the rats in such ports and towns destroyed. The wise precautions of Australia, as those of Turkey would seem to be, were prompted by actual experience, but Europe, though for the most part at present free from plague, might profitably adopt in advance for international protection those measures which the unfortunate experience of these two countries has shown to be essential. The policy of "rat-destruction" on all trading vessels has been found simple of attainment in Australia, and if adopted by every nation need cause little or no interference with trade, for when owners once recognised its necessity they would readily arrange for the destruction of rats by fumigation at the end of each voyage.

A COMPLIMENTARY dinner is to be given to-night, Saturday, Dec. 14th, to Mr. George Jacob Holyoake, the veteran social and political reformer. Mr. Holyoake, during his long career as an agitator (this is his own description of himself) has been a consistent worker for the public good. He was one of the most prominent in continuing the work begun by Joseph Hume, Thomas Wakley, the founder of THE LANCET, Lord Lytton, Daniel Whittle Harvey, and others, which resulted in the freeing of the press from the onus of stamp duties. It is on record that Mr. Holyoake incurred, by refusing to submit to the legislation of the "fifties," fines amounting in the aggregate to £600,000, a sum which he proposed to pay to the Chancellor of the Exchequer in weekly instalments. The public, to whom the vigorous octogenarian is only a name, are to have a taste of his editorial vigour, for Mr. Holyoake has been requested, and has consented, to edit the *Sun* for the week preceding Christmas.

## THE PLAGUE IN INDIA.

BY ALEX. GRAHAM-SIMPSON.

## I.—SYSTEM OF HARBOUR INSPECTION.

THERE is little wonder that the Orient liner *Ormuz* at Marseilles recently refused to go into quarantine considering what quarantine at Marseilles means. The writer has had experience both of the French and Spanish methods in regard to plague and quarantine. From the point of view of inspection they are most unsatisfactory; while in respect to quarantine the less said about them the better. If the authorities in these countries wish for an example of the perfection of medical work of this class they must go to India, particularly to Bombay. An account of how Europe is there safeguarded from the spread of the terrible disease at the present moment may prove of interest.

How great is the work entailed and how thoroughly it is carried out may best be understood from the fact that not a single native boat of any size whatsoever crosses Bombay harbour unless the occupants of the craft have been medically examined and reported upon. As regards vessels going to foreign ports the care exercised is of the minutest character. All passengers are medically examined on shore prior to embarkation, and officers and crew without exception have to undergo a similar ordeal. The time of departure for every ship is notified to the port health officer and recorded, so that each day brings a long programme of work, extending from sunrise to sunset, which has to be divided among the members of his staff. This consists of four fully-qualified European medical men, two European lady practitioners, a large number of subordinates, and a special corps of some 50 police.

As soon as the hold of a vessel is empty it has to be washed and disinfected, lest germs have been left there by the coolies who have assisted in unloading the cargo; and, when again at sea, the bilge water, which has been liberally treated with carbolic acid, has to be pumped out. Fore-castle and cabins are thoroughly washed with disinfectants, while, as regards the men's quarters, it is insisted, not only that the inside of their bunks shall be so cleansed, but that the bottoms underneath shall undergo the same process. Carbolic powder is sprinkled all over. The medical authorities are furnished with a complete list of the crew and of every box belonging to them.

## STEAMING PROCESS AT MALET BUNDER.

Before the departure of the vessel each man has to go ashore with all his belongings. If he has not had the good sense to attire himself in the cleanest clothes of which he is possessed he is made to do so. What he has put off is taken to that portion of the harbour known as Malet Bunder, and, along with the contents of his trunks, is placed in an iron cradle of huge dimensions. This, when full, is run on wheels along little rails into an immense boiler. Here for 15 minutes the articles are subjected to steam at a pressure of 10 pounds to the square inch, the temperature attained being no less than 239° F. Three times during those 15 minutes the steam is changed; and for five more minutes the clothes are subjected to hot air. The result is that the great iron cylinder becomes the tomb of every microbe that has been encased within it, and the hot air so dries everything that, excepting in the inmost folds, no trace of the steam can be found. What little damp remains vanishes on exposure to the air.

But while all this "cooking" has been going on the medical man has not been idle. He carefully examines the owner of the clothes.

In a large shallow tank at the end of the inspection sheds every box is washed and disinfected within and without. The crews of the P. and O. steamers have their boxes cleaned at the company's expense each voyage and covered with quick-drying red paint. In other cases the boxes are whitewashed. The date of the cleaning is carefully stamped upon the bottom of the trunks and a corresponding mark is placed upon the arms of the owners. The clothes are repacked. Men and boxes are then sent on board and are not allowed to come on shore again, policemen being kept on watch lest the rule should be broken. The number of men is checked by the ship's articles; and during their

absence their quarters are searched to see that nothing which ought to have been disinfected has been kept back. On the departure of each batch the floor of the inspection shed is swept perfectly clean and the dust thus collected is burned. There seems to be no possible chance for the existence of germs. Regarding passengers, especially natives, the rules are most strict. None are allowed on board a boat thus prepared for sea by the medical authorities without the production of a ticket certifying that they have been thoroughly examined and are free from disease. As with the crew, once on board, there they have to stay.

All this is not sufficient, however. At the last moment, before the vessel leaves the harbour, one of the Port Health Staff goes on board. The roll of the crew is again called. Again they are examined and again their trunks are counted. Woe to the ship with an extra man or a box that does not bear the stamp of official approval! At the very least it will mean that the whole process of disinfection will be repeated after the removal of the guilty individual or the offending property.

## SCENES AT MODY BUNDER.

The protection of foreign ports, however, does not alone occupy the attention of the Indian Government. At immense expense India, too, has to be sanitarily safeguarded. From Mody Bunder every week thousands of natives travel by steamer to different places along the coast. Every one of these is examined in the Bunder shed constructed specially to facilitate inspection. It is impossible for a single person to enter without being seen. At each end is a compartment where in the one men and in the other women may be called to undergo further examination if the first inspection has aroused suspicion in the mind of the medical man. Lady practitioners are, of course, employed to look after those of their own sex and the greatest care is taken that, so far as is consistent with thoroughness, caste prejudices are not aroused.

Before the departure of the steamers hundreds of would-be passengers congregate outside the long corrugated-iron shed awaiting admission. Once the doors are opened they stream in, a motley throng, and, toeing a mark on the floor, face the rising sun. The doctor passes down the row, taking temperatures and looking at tongues. Many of these passengers have been through the operation before and they sit patiently with tongues cut and eyes shut awaiting the ordeal. At times the sight is very funny. Add to this the solemnity of the Oriental and the picture is easier to imagine than describe. But this is scarcely more amusing than the expression of relief that overspreads the features of those examined when they learn that all is well. Sick people rarely present themselves for examination. They have learned by experience that it is almost impossible to escape the vigilance of expert officers.

The local passenger boats, in the same way as those journeying to European ports, are subjected to the most rigorous cleanings and disinfectings, and though most of the staff are engaged during the remainder of the day in visiting the ships in the stream and at the docks, there is always one medical officer on duty at the coasting company's shed to see that everything is conducted in the way desired by Government.

## THE VENICE CONVENTION.

Of the inspection of inward-bound vessels little need be said, excepting that it is equally thorough and, added to the duties of the Port Health Staff already enumerated, makes them without doubt one of the most hard-worked bodies of officials in India. It is no matter of surprise that when the Indian delegate at the Venice Convention, after a close investigation of the system, explained it to his colleagues his statement was received "with satisfaction mingled with incredulity." Members of foreign scientific commissions who have passed through India to study plague have expressed astonishment and admiration at the completeness of the inspection, and when the Venice Convention regulations were published it was found that they provided nothing essential that was not already in force in India. It was ruled, however, that all persons prior to embarkation were to be inspected first on shore, and this, as will be apparent from what has been stated, has been complied with most scrupulously.

## INTERESTING STATISTICS.

The magnitude of the work done will be seen from the statistics. From February to May, 1897, 1038 square-rigged vessels and 16,154 native craft were inspected. Of passengers

182,386, and of members of crews 143,906, were examined, of whom 678 among the former and 153 among the latter were rejected. From June, 1897, to May, 1898, the number of square-rigged ships had risen to 2488 and the number of native craft to 48,730. There were 355,409 passengers and 458,462 members of crews inspected, of the passengers 10,635 being rejected and of the seamen 687. From June, 1898, to May, 1899, there was again an increase, the numbers being 2708 square-rigged ships inspected, 57,480 native craft, 546,881 passengers, and 695,136 members of crews. Of these the passengers rejected numbered 15,380 and of the members of crews found medically unfit there were 1314.

During the entire period, therefore, no fewer than 128,598 ships of various sorts had to be visited and 1,102,180 persons examined.

Bombay was visited three times by virulent epidemics of plague and was not once free from the disease. Nevertheless, only seven cases were reported as having occurred on ocean vessels. The first, it appears, was that of a pilgrim and occurred on a pilgrim-ship in 1897. The second was discovered on a military transport in the March of the same year. The passengers of the vessel had been examined by the military and not by the port officials. Two other cases were found on board P. and O. liners in March, 1898, during voyages between Bombay and Aden, and the remaining three occurred on the same line—one of a Lascar which proved fatal at Colombo, another of a native fireman who died at Aden, and the third of a native passenger whose death took place also at Colombo. At the time of writing it was not possible to ascertain accurately if many cases occurred among the millions of the crews and passengers who left Bombay for coast ports, but very few had been detected.

These facts speak volumes for the thoroughness and success with which the operations entrusted to them have been, and are being, carried out by the Port Health Staff at Bombay, whose duties, arduous as they are monotonous and often disgusting, have been fulfilled with a devotion worthy of the highest praise. The Indian treatment of quarantine patients France and Spain might copy with advantage, and they would benefit greatly by a more careful study and practice of every detail of the preventive system.

### THE ELECTION OF DIRECT REPRESENTATIVES ON THE GENERAL MEDICAL COUNCIL.

On Tuesday afternoon, Dec. 10th, the result of the election of Direct Representatives for England and Wales upon the General Medical Council was made known. The voting resulted as follows:—

MR. GEORGE JACKSON...	6518
MR. GEORGE BROWN ...	5369
DR. S. WOODCOCK ...	3161
DR. C. W. HAYWARD ...	1385

Mr. George Jackson therefore takes the seat left vacant by the retirement of Dr. Glover, while Mr. George Brown is re-elected for a further term of five years.

We have received the following letters for publication:—

TO THE REGISTERED PRACTITIONERS OF ENGLAND AND WALES.

FELLOW PRACTITIONERS,—I thank you very sincerely for the great honour you have done me in re-electing me, by an increased majority, as one of your Representatives on the General Medical Council, and I beg to assure you that in discharging the duties of the office I shall continue, as heretofore, to do all I can, having due regard to the claims of the public, to promote the welfare and best interests of the profession.—I remain, your obedient servant,

GEORGE BROWN.

6, Gibson-square, London, N., Dec. 11th, 1901.

TO THE REGISTERED MEDICAL PRACTITIONERS OF ENGLAND AND WALES.

FELLOW PRACTITIONERS,—I have to offer you my most sincere thanks for having returned me to represent your

interests as a Direct Representative on the General Medical Council. I feel greatly the honour you have conferred on me, and hope to be able to help to carry out the reforms which we all desire to see accomplished.

I remain, your obedient servant,

GEORGE JACKSON, F.R.C.S. Eng.

10, Portland-villas, Plymouth, Dec. 11th, 1901.

To the Editors of THE LANCET.

SIRS,—Will you allow me through the medium of the columns of THE LANCET to express my hearty thanks to those ladies and gentlemen who voted for me in the election? I am, of course, well aware that it is to the principles which I advocated that I owe so large a measure of support.

I am, Sirs, yours faithfully,

Manor-place, Edinburgh, Dec. 9th, 1901. NORMAN WALKER.

## Looking Back.

FROM

THE LANCET, SUNDAY, DEC. 14, 1823.

CONDUCT OF THE SURGICAL CLASS AT THE BOROUGH PREVIOUS TO SIR ASTLEY COOPER'S ENTRANCE.

To the Editor of The Lancet.

Dulce est desipere.

SIR,—Your facetious Correspondent, who recommended push-pin, and a variety of other games, to the adult members of the profession, in the last week's LANCET, would, perhaps, deem his advice unnecessary, if he were to witness the scenes which take place in the theatre of St. Thomas's Hospital, during the half hour previous to the entrance of Sir Astley Cooper. Students, already so accomplished in the branches of science pointed out by your Correspondent, can need no additional instruction. What an interesting spectacle, Mr. Editor, to see a body of young men assembled for the purpose of acquiring professional knowledge, actively engaged in discharging masticated paper and apple into each other's faces; or employed in the no less intellectual occupation of twirling round the Lecturer's table, or sprinkling dirt on the heads of those who happen to sit under them! I have been educated at Edinburgh; and have attended the medical schools of our continental neighbours, and I can assure you that the students of St. Thomas's are not only far greater proficient in these accomplishments than their graver brethren of the North, but that if a student from the *Ecole de Médecine* were introduced into the theatre in the Borough, he would be compelled to acknowledge the inferior vivacity of a class of French students. Such an admission would, no doubt, be very humiliating, but the students in the Borough are entitled to it; *palmarum qui meruerunt ferant*.

Yours truly,

EDINENSIS.

Prizes proposed by the Royal Society of Medicine at Bourdeaux.

PATHOLOGISTS having admitted that there existed disease in which no alteration of the organic tissues could be discovered, have employed various terms to designate them. In the present improved state of pathological anatomy, accurate examinations of a great number of bodies after death have established the fact that certain diseases which have been hitherto supposed to be entirely produced by injuries of the vital functions, were in fact kept up by true organic injuries. Relying upon these recent discoveries, some physicians contend that there can be no disease without organic injury. In this state of our knowledge, the Society at Bourdeaux has considered it a favourable moment to propose to the discussion and decision of practitioners the following questions:

Do any diseases exist, in which the vital functions are alone injured, without any alteration of the organic tissues? Can these diseases be recognized and demonstrated by

positive characters, and subsequently confirmed by examinations after death?

A prize of the value of 300 francs will be adjudged to the best Essay on this subject, at the general meeting in 1824.

A similar prize will be adjudged to the best Essay on the following questions, at the meeting in 1825:

Can medicinal substances be safely injected into the venous system of man? What are the medicinal substances which can be introduced into the animal economy in this manner? And what are the diseases which require this mode of treatment?—*Journal Complémentaire du Dictionnaire des Sciences Médicales*, Nov. 1823.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

In 33 of the largest English towns 6358 births and 4292 deaths were registered during the week ending Dec. 7th. The annual rate of mortality in these towns, which had been 19.4 and 20.3 per 1000 in the two preceding weeks, declined again last week to 19.5 per 1000. In London the death-rate was also 19.5 per 1000, and corresponded with the average rate in the 32 large provincial towns. The lowest death-rates in these towns were 13.6 in Croydon, 14.0 in Portsmouth, 14.3 in Derby, and 15.3 in Bradford; the highest rates were 23.0 in Manchester, 23.9 in Oldham, 28.6 in Blackburn, and 29.3 in Norwich. The 4292 deaths in these towns last week included 135 from measles, 70 from diphtheria, 64 from whooping-cough, 50 from scarlet fever, 44 from "fever" (principally enteric), 30 from diarrhoeal diseases, and 16 from small-pox. In all, 417 deaths resulted from these principal zymotic diseases, against 427, 443, and 434 in the three preceding weeks. No death from any of these diseases occurred last week in Huddersfield; in the other towns they caused the lowest death-rates in Croydon, Cardiff, Hull, and Gateshead, and the highest rates in Birmingham, Norwich, Manchester, Oldham, Blackburn, and Halifax. The greatest proportional mortality from measles was recorded in Norwich, Manchester, Oldham, Blackburn, Halifax, and Sheffield; from scarlet fever in Birmingham; from "fever" in Plymouth; and from diarrhoeal diseases in Swansea, in Nottingham, and in Burnley. The mortality from whooping-cough showed no marked excess in any of the large towns. The 70 deaths from diphtheria in these towns included 36 in London, five in Liverpool, four in Sheffield, three in West Ham, and three in Bristol. 16 fatal cases of small-pox occurred in London, but not one in any of the 32 large provincial towns. There were 474 cases of small-pox under treatment in the Metropolitan Asylums hospitals on Saturday, Dec. 7th, against 368, 396, and 427 at the end of the three preceding weeks; 170 new cases were admitted during the week, against 113, 141, and 123 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 3353, 3336, and 3278 on the three preceding Saturdays, had further declined to 3241 at the end of last week; 377 new cases were admitted during the week, against 376, 379, and 320 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 582 and 534 in the two preceding weeks, further decreased last week to 470, but were 33 above the corrected average. The causes of 42, or 1.0 per cent., of the deaths in the 33 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Nottingham, Bradford, Leeds, and in 14 other smaller towns; the largest proportions of uncertified deaths occurred in Liverpool, Blackburn, Preston, Sheffield, and Sunderland.

### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19.9, 21.3, and 22.2 per 1000 in the three preceding weeks, declined again to 20.5 per 1000 during the week ending Dec. 7th, but was 1.0 per 1000 above the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 14.2 in Perth and 14.4 in Paisley to 23.6 in Aberdeen and 24.8 in Leith. The 653 deaths in these towns included 23 which were referred to measles,

21 to diarrhoea, 10 to "fever," nine to scarlet fever, five to diphtheria, and four to whooping-cough. In all, 72 deaths resulted from these principal zymotic diseases last week, against 85 and 77 in the two preceding weeks. These 72 deaths were equal to an annual rate of 2.3 per 1000, which was 0.4 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of measles, which had been 29 in each of the two preceding weeks, declined last week to 23, of which 20 occurred in Glasgow and two in Dundee. The deaths from diarrhoea, which had been 30 and 21 in the two preceding weeks, were 21 last week, and included eight in Glasgow, five in Dundee, four in Edinburgh, two in Aberdeen, and two in Leith. The fatal cases of "fever," which had been 12, eight, and nine in the three preceding weeks, rose again last week to 10, of which seven were registered in Glasgow and two in Paisley. The deaths from scarlet fever, which had been eight, six, and three in the three preceding weeks, increased to nine last week and included four in Glasgow, three in Greenock, and two in Edinburgh. The fatal cases of diphtheria, which had been six and eight in the two preceding weeks, declined again last week to five, of which four occurred in Glasgow, where the four deaths from whooping-cough were also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 177 and 186 in the two preceding weeks, decreased again last week to 180, but were 29 in excess of the number in the corresponding period of last year. The causes of 27, or more than 4 per cent., of the deaths in these eight towns last week were not certified.

### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23.8 and 18.8 per 1000 in the two preceding weeks, rose again to 20.2 during the week ending Dec. 7th. During the past four weeks the death-rate has averaged 21.7 per 1000, the rates during the same period being 20.6 in London and 18.7 in Edinburgh. The 145 deaths of persons belonging to Dublin registered during the week under notice were 10 in excess of the number in the preceding week, and included six which were referred to the principal zymotic diseases, against nine and seven in the two preceding weeks; of these, three resulted from diarrhoeal diseases, one from scarlet fever, one from diphtheria, and one from "fever," but not one from either small-pox, measles, or whooping-cough. These six deaths were equal to an annual rate of 0.8 per 1000, the zymotic death-rates in the same period being 1.5 in London and 1.3 in Edinburgh. The three deaths from diarrhoeal diseases showed a slight decline from the number in the preceding week. The 145 deaths in Dublin last week included 23 of children under one year of age and 38 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a slight decline from the respective numbers recorded in the preceding week. Four inquest cases and two deaths from violence were registered, and 57, or more than a third, of the deaths occurred in public institutions. The causes of 12, or more than 8 per cent., of the deaths in Dublin last week were not certified.

## THE SERVICES.

### ROYAL ARMY MEDICAL CORPS.

THE under-mentioned officers are placed on temporary half-pay on account of ill-health:—Lieutenant-Colonel F. A. Harris (dated Oct. 24th, 1901); Captain J. E. Carter (dated Dec. 1st, 1901).

Major J. H. Nicholas, retired pay, has arrived for duty at Derby and has assumed medical charge of the station hospital and troops. Captain F. R. Buswell has been permitted to extend his tour of Indian service until the next trooping season. Captain G. B. Stanistreet proceeds to Southampton for duty.

### INDIA AND THE INDIAN MEDICAL SERVICES.

Major C. C. Manifold, Indian Medical Service, to be Lieutenant-Colonel in recognition of services during the operations in China. The award bears date Nov. 29th, 1901.

### VOLUNTEER CORPS.

*Submarine Miners*: The Forth Division: Surgeon-Lieutenant J. Wilson to be Surgeon-Captain. *Rifle*: 6th Volunteer Battalion the Royal Scots (Lothian Regiment): Harold

Sherman Ballantyne to be Surgeon-Lieutenant. 2nd Volunteer Battalion the Prince of Wales's Own (West Yorkshire Regiment): Surgeon-Lieutenant-Colonel S. Johnson resigns his commission, with permission to retain his rank and to wear the uniform of the battalion on retirement. 2nd Volunteer Battalion the East Lancashire Regiment: Surgeon-Captain C. E. R. Bucknill resigns his commission. 2nd (South) Middlesex: Surgeon-Major S. H. Moore resigns his commission, with permission to retain his rank and to wear the uniform of the corps on retirement.

#### VOLUNTEER MEDICAL STAFF CORPS.

The Manchester Companies: Herbert George Parker to be Surgeon-Lieutenant.

#### SOUTH AFRICAN WAR NOTES.

Civil Surgeons Lavertine, Dickenson, Strange, Ward, McLean, and Gould have been discharged from hospital to duty.

Major B. M. Skinner, R.A.M.C., is returning to England from South Africa in the s.s. *Tagus*.

Civil Surgeon McCabe, reported missing at Doornkop on Nov. 28th, has rejoined.

On Dec. 7th, at Dublin Castle, the Lord Lieutenant of Ireland presented war medals to the members of the Irish Hospital Corps which returned recently from South Africa.

The Imperial Yeomanry Hospital at Elandsfontein will be transferred to the authorities on Dec. 28th and the medical officers, sisters, and other members of the staff will return to England by the first available transport.

#### AFFAIRS IN SOUTH AFRICA.

As far as the purely military aspect of affairs is concerned there seems to have been an increased activity in South Africa of late and the progress of events has been going on at a somewhat accelerated pace. We can only trust that Sir Gordon Sprigg will prove correct in expressing his conviction that the war is fast drawing to a close. The total casualties that have been incurred from the beginning of hostilities up to and including last month mount up to a considerable figure. The total reduction of the military forces through the war, including deaths in South Africa, missing, and prisoners, deaths among invalids sent home, and invalids discharged the service as permanently unfit, amount to 907 officers and 22,564 rank and file = 23,471. It may be mentioned as a satisfactory fact that a great majority of the men invalided home have recovered and rejoined for duty. As regards the Boer population in the concentration camps there is no doubt that there has been a deplorable amount of sickness and death. The occupation of these camps was apparently unavoidable under the circumstances and was dictated as a matter of humanity to the Boer families as much as one of military and general policy. As far as we understand, the camps no longer remain under the control of the War Office, but have passed under the authority of the Colonial Office and are, as far as practicable, to be split up and a number of practical changes are to be introduced and carried out in regard to them.

#### THE LATE SIR WILLIAM MACCORMAC.

The *Times* of Dec. 9th publishes a letter from Sir William MacCormac to Sir James Blyth written while on the way home from South Africa in April last:—

I have accomplished a great deal—I am myself astonished how much—during the four and a half months I was in the country. I have visited all the hospitals in Natal and in Cape Colony and have seen the working of the field hospitals at the front—where I have been four times—the hospitals, and hospital trains along the lines of communication, and the base hospitals; and, to make the experience complete, I have been a patient in hospital myself with a short attack of dysentery, which was sufficiently unpleasant and painful. You will grant that I am qualified so to speak when I affirm that never were medical arrangements better or more complete, or an expedition ever sent out more thoroughly and lavishly supplied with everything that medical foresight could suggest. I have been consulted in cases innumerable; and, in doing what I have sketched, have had to travel over more than 6000 miles of country. The powers that be out here, from Lord Roberts downwards, have expressed themselves very flatteringly, and I have myself the conviction, I hope not misplaced, that I have been able to do some public service. When we meet I will tell you of my adventures. I am glad, and yet sorry, to return, but practically Lord Roberts insisted, and it was a command virtually. He said I had done my share and earned a rest. I do not think I could have done more than repeat what I had already done had I remained; and there is much for me to do at home.

Surgeon-Major-General A. M. Tippetts, retired list, A.M.S., has been granted a distinguished service reward of £100 a year.

#### LADY BADEN-POWELL'S APPEAL.

Lady Baden-Powell, in thanking the press for making known the scheme for sending a small Christmas present to each man in the South African Constabulary, states that the required sum of £1000 has now been raised, some friends of the corps having undertaken to make up the very small deficiency. For the information of those who have given donations Lady Baden-Powell mentions that none of the money has been used for any expenses incurred in forwarding the goods, postages, agency, &c. Each man of General Baden-Powell's force has been sent a Christmas pudding, half a pound of tobacco, a pipe, and a handkerchief. In addition, supplies of books, magazines, clothing, chocolate, cigarettes, &c., which have been sent by friends, have been forwarded. Some large and generous donations have been received, but a great part of the funds has been made up in small sums—even schoolboys and servants foregoing their Christmas presents in order to send the money to those who are so far from the good cheer of their home circle this Christmastide.

#### THE IRISH HOSPITAL CORPS.

Earl Cadogan, the Viceroy of Ireland, on Saturday afternoon last presented medals to the Irish Hospital Corps who served in South Africa. His Excellency was accompanied by the Duke of Connaught and a distinguished company, and after presenting the medals to Sir William Thomson, Mr. George Stoker, and other members of the corps, gave an address highly eulogising the work they had done and the great services they had rendered at the seat of war. In the course of his address Lord Cadogan alluded to the service rendered by the late Sir William MacCormac and to the noble and pathetic story of Mr. W. Smyth of Donegal. Sir William Thomson, in returning thanks on behalf of the Hospital Corps, said that they were especially proud to have been permitted to take part in the glorious work of succouring the sick and wounded of friend and foe in South Africa.

#### CHANGES IN THE ARMY MEDICAL SERVICE.

Surgeon-General W. Taylor, C.B., having arrived home, as we announced last week, to take up his appointment as Director-General of the Army Medical Service, it will be necessary to fill up the post he has vacated of Surgeon-General to His Majesty's forces in India, and there naturally exists some interest as to the medical officer to be nominated for the purpose. Surgeon-General W. S. M. Price is officiating as head of the British Medical Service in India in the meantime. Owing to the occurrence, or shortly anticipated occurrence, of vacancies in the rank of surgeon-general several promotions should soon take place.

## Correspondence.

"Audi alteram partem."

### RASH AFTER TONSILLOTOMY.

To the Editors of THE LANCET.

SIRS,—As I am much interested in all "rashes" I would raise the question whether the non-specific rash following Mr. H. W. Henshaw's operation (recorded in THE LANCET of Nov. 30th, p. 1531) did not arise from the administration of a soap-and-water enema either before or after the operation? This is an exceedingly common cause of such eruptions in children.

I am, Sirs, yours faithfully,

Rugby, Dec. 4th, 1901.

CLEMENT DUKES.

To the Editors of THE LANCET.

SIRS,—With reference to the remark of Mr. H. W. Henshaw in THE LANCET of Nov. 30th, p. 1531, on a rash following the removal of tonsils and adenoids I should like to say that a similar case occurred to me recently after removal of adenoids alone from a girl, aged 13 years. The rash occurred two days after operation and covered the chest, abdomen, back, and limbs, but not the face, hands, or feet, being thus similar to Mr. Henshaw's case. It was red, punctiform, and raised, and there was a little irritation on the chest. The temperature was not raised and the patient

felt perfectly well. The rash disappeared gradually and was gone in two days, leaving no desquamation. Very little chloroform was given, no drugs were administered, and there was no alteration in diet.

I am, Sirs, yours faithfully,  
Ramsgate, Dec. 7th, 1901. H. W. REYNOLDS, M.B., B.Sc.

*To the Editors of THE LANCET.*

SIRS,—In respect to your note to my communication published in THE LANCET of Nov. 30th, p. 1531, recording the occurrence of a rash after tonsillotomy, I trust that you will permit me to answer your inquiries and to explain that I omitted the details you mention because they seemed of quite negative value. No drugs whatever were being taken. The only change of diet was the usual one of placing the patient on fluid food for a short time after the operation. Chloroform was the anæsthetic employed. It is, of course, often most difficult directly to associate cause and effect, but in this case there was no obvious reason for the eruption apart from operation, and I therefore felt justified in regarding it as an instance of "tonsillotomy rash," of which Wingrave recorded 30 cases in the *Laryngoscope* of July, 1901.

I am, Sirs, yours faithfully,  
H. W. HENSHAW, M.R.C.S. Eng., L.R.C.P. Lond.,  
Kew, Dec. 10th, 1901. D.P.H. Lond.

## AN ELECTRO-THERAPEUTICAL SOCIETY.

*To the Editors of THE LANCET.*

SIRS,—I was pleased to see in THE LANCET of Dec. 7th, p. 1611, a letter from Mr. Chisholm Williams asking for support in the formation of a society for those practising electro-therapeutics. In this country we are sadly behind many of our continental neighbours in the use of the physical forces in the treatment of disease and this is more especially the case with electricity. Hitherto it has been left to the few who have learned to appreciate the immense value of the intelligent use of electricity in medical treatment to combat as best they can the grave prejudice existing in the mass of the profession against what may be called electrical treatment. Such a society, if well supported, should do much to rescue electro-therapeutics from the lay "medical electrician" and the vendor of the so-called "electric" belts. As one who has for many years worked in this field, and who relies largely upon electricity as a therapeutic agent, I shall be pleased to give such a society every help in my power.

I am, Sirs, yours faithfully,  
RICHARD J. COWEN, L.R.C.P. Irel., &c.  
Clarges-street, Mayfair, W., Dec. 9th, 1901.

*To the Editors of THE LANCET.*

SIRS,—Referring to Mr. Chisholm Williams's letter of last week suggesting the formation of a new society, will you allow me to say that the council of the Röntgen Society have for some time past been considering the advisability of enlarging its scope so as to include the investigation of other radiations than those immediately connected with its name. The president in the address he delivered on Nov. 7th last expressed these views somewhat fully and it has since been decided to carry them out and the question of a possible modification in the name of the society is also under consideration. The object Mr. Williams desires to effect by forming a special medical society has not been lost sight of, but it is felt that the new therapeutic agents such as high-frequency electric currents, Finson light, &c., call for so much further investigation that it would not be wise—certainly at present—to exclude the valuable help of physicists who have leisure to undertake such inquiries, few medical men having the time at their disposal for original research. This plan has worked very well in our society in the matter of x rays, the result being that the medical profession has now in its hands better apparatus and fuller knowledge than would have been possible had there not been the coöperation of which I speak.

I am, Sirs, yours faithfully,  
J. J. VEZEY,  
Dec. 9th, 1901. Honorary Treasurer to the Röntgen Society.

*To the Editors of THE LANCET.*

SIRS,—I trust that the scheme spoken of by Mr. Chisholm Williams in THE LANCET of Dec. 7th (p. 1611) will bear

practical fruit. An electro-therapeutical society is really wanted.

I am, Sirs, yours faithfully,

Dec. 12th, 1901.

M.B.

\* \* A society which would bring together those who are working at the subject of medical electricity might be a useful thing, although we are always a little loth to recommend the addition of a new scientific society to the already lengthy list of such bodies. But additions to the ranks of those interested in electricity have been numerous lately and it may reasonably be supposed that there are now enough to keep a special society alive. Of matters to be discussed there is no lack; what is required is a gathering of persons qualified to discuss them.—ED. L.

## THE ADMINISTRATION OF CHLOROFORM.

*To the Editors of THE LANCET.*

SIRS,—In THE LANCET of Nov. 23rd, p. 1418, is an account of the opening meeting of the Society of Anæsthetists. The difference of opinion expressed shows the lack of clear thought that exists in the profession with regard to the safe administration of chloroform. In no one instance was *personal* experience advanced. Observation is one thing; to speak from actual personal knowledge in conjunction with observation is another. It seems to me that a multiplicity of words only fogs the subject and that the matter is in a nutshell. At any rate, I am ready at any time to prove before any number of the profession that chloroform *when properly administered* is, and ought to be, free from danger and all bad after-effects worth naming. This I am willing to demonstrate by taking it to the stage of surgical anæsthesia by a *Krohne inhaler* and then getting up and riding away on my tricycle. Surely it is time this question should be definitely settled so that the public may always have it rightly administered. The whole question is one of overdosing.—I am, Sirs, yours faithfully,

C. J. HARRIS, M.R.C.S. Eng., &c.  
Kilburn Priory, N.W., Dec. 3rd, 1901.

## AN UNDESCRIBED (?) SYMPTOM IN WHOOPING-COUGH.

*To the Editors of THE LANCET.*

SIRS,—I should like to draw the attention of your readers to a symptom which I have both experienced and observed in whooping-cough and which, if it receives corroboration, may prove of assistance in the diagnosis of this very troublesome disease. I had the misfortune last summer to contract whooping-cough from a hospital case and subsequently to infect my two children. In my own case I had the usual preliminary catarrhal stage, followed by paroxysmal cough, the fits being so prolonged as to result on one occasion in the rupture of some fibres of one of the abdominal muscles. During the whole course of the illness—some seven or eight weeks—I whooped only twice or three times. But after every paroxysm of at all a severe nature a series of what one might perhaps call deglutition spasms set in, and I had to gulp down saliva as quickly as possible for a minute or two, the interval between the gulps gradually lengthening and the paroxysm finally passing off.

I found it quite impossible to control these gulps, though I tried hard. The sensation was a most unpleasant one as were also the consequences, for one's stomach became largely filled with air. I noticed the same symptoms in both of my children though only at such times as they did not whoop. I also observed it in two children at the Stockport Fever Hospital, again at times when they did not whoop. Apart from this symptom all the cases mentioned were quite typical. I do not find any mention of this symptom in Fagge, Goodhart, Taylor, Watson, or Carter, and none of the medical friends to whom I have spoken have ever observed it. It appears to me, however, that it is worth while bringing it to the notice of your readers in order to see whether it has been observed and recorded before or not. My own experience of it was quite sufficient to impress me with its unmistakable character.

I am, Sirs, yours faithfully,  
Stockport, Dec. 5th, 1901. MEREDITH YOUNG, M.D. Edin.

## UNDERFED CHILDREN IN THE BOARD AND VOLUNTARY LONDON SCHOOLS.

*To the Editors of THE LANCET.*

SIRS,—Will you permit me once more to appeal to the charitable public through your columns on behalf of the funds of the London Schools Dinner Association? That association provides cheap or free meals for underfed children in the board and voluntary schools of London. The grants which it makes for that purpose are administered by local committees upon which the managers and teachers are represented. These committees ascertain by proper inquiry that the need of application for relief is real and undertake the economical provision and distribution of suitable food.

Last winter the underfed children in 181 schools were thus relieved, under the administrative control of 79 local committees. About 660,000 meals were provided, of which 102,800 were paid for wholly or partly, by the recipients. The total receipts from donations were £1186, but the amount spent in the provision of meals alone was £1286. This is the third year in which the necessary expenditure of the association has exceeded its income. The total deficit for that period now amounts to more than £700, and the accumulations of earlier years, when income exceeded expenditure, are now practically exhausted. Unless, therefore, the association receives a substantial increase of income at an early date, its necessary and beneficent work will have to be curtailed.

Cheques and postal orders should be made payable to "The London Schools Dinners Association," and crossed "Barclay & Co.," and forwarded to the Secretary, 117, School Board Offices, Victoria Embankment, W.O.

I am, Sirs, yours faithfully,

REAY,

Chairman of the School Board for London.

## THE LATE R. B. ANDERSON FUND.

*To the Editors of THE LANCET.*

SIRS,—With reference to the affairs of the late Mr. R. B. Anderson, it may be within the recollection of your readers that in July last we made an appeal to the profession for subscriptions towards the support of his widow and their twin sons. This subscription now amounts to about £80, a very inadequate sum; but the committee feel that it is useless to keep the fund open much longer. It has therefore been decided to close it on Wednesday, Jan. 8th, 1902, and to make an earnest appeal in the meanwhile for further donations. The amount realised will at once be sent out to the island of Tobago to be used for the benefit of Mrs. Anderson and her two sons at the discretion of the Warden of that island. We may add, in view of a rumour which has prevailed that the Civil Rights Defence Committee was dissolved in consequence of some misconduct on Mr. Anderson's part, that the only reason for the dissolution of that committee was its failure to collect, in the time given for that purpose, the funds required for the contemplated appeal to the Privy Council.

Donations are to be marked "for the late R. B. Anderson Fund," and to be sent, and cheques, &c., made payable, to the Manager, Union Bank of London, Chancery-lane, London, W.C. They will be duly acknowledged.

We are, Sirs, yours faithfully,

STAMFORD, Chairman.

Dec. 9th, 1901.

TIMOTHY HOLMES, Hon. Treasurer.

## THE DANGERS OF A COMMON COLD.

*To the Editors of THE LANCET.*

SIRS,—The evidence that all colds are infectious and that without the presence of infection it is impossible to catch a cold is probably far stronger than your correspondent Dr. Clayton Jones thinks. Colds are almost unknown in the Arctic Circle, not on account of the action of the continuous cold, but because the greater part of that region is uninhabited. When Sir William Conway and his men were exploring Spitzbergen, though they were exposed to great privations and were almost constantly wet through, they never caught a cold, but directly they came down to Andrée's

settlement on the coast, where some 40 men were living in almost constant intercourse with the mainland, they all developed violent colds. Nansen and his men never caught a cold during all the three years of his voyage, notwithstanding the utmost exposure, but directly they reached civilisation on the coast of Norway, though still within the Arctic Circle, they all suffered badly from colds. The weather is not always keen and bracing in the Arctic regions; during the summer-time in Franz Josef Land, at any rate, it is exceedingly damp, and raw mist-laden east winds prevail; yet the members of the Jackson-Harmsworth Expedition never caught a cold there, though all but two of them did so directly they reached civilisation. More noteworthy still were Conway's experiences in the Himalayas. While amongst the mountains he and his men, notwithstanding great exposure, never caught colds; nor did they even when they visited the small remote native villages; but once they came down to a village where there was a small European settlement in communication with the outer world, and there they all took bad colds. Nor is it only in the Arctic regions and amongst high mountains that colds are absent; the same immunity from them is noticeable during long sea voyages and when camping out in the desert; and, still more unexpectedly, in the best open-air sanatoriums, such as Nordrach, where the ventilation is practically perfect, it is found that the patients do not catch cold. There is, I believe, plenty of other evidence to show that there are places remote from ordinary human life where colds cannot be caught whatever the exposure; probably many of your readers can bring forward instances. On the other hand, that ordinary colds are in the highest degree infectious is now becoming a matter of common knowledge, and any medical man if he goes about with open eyes can collect evidence for himself. I have watched a cold pass from house to house and have even traced it from one village to another and have listened, not without some amusement, while the different sufferers from it have explained to me just how they caught it—ascribing it to some open window, change of garment, or other fancied imprudence. I know houses where all the members of the household, including visitors and children, are constantly catching colds, and they are not the airy or even the draughty houses, but stuffy, grimy, badly ventilated, and dark ones. No doubt it is possible to have an inflammation of the nasal mucous membrane, as of the conjunctiva, from some simple irritant, but such an event is rare, whereas the ordinary infectious cold is by far the commonest of all diseases. Surely, therefore, it is important that its infectiousness should be frankly recognised.

I am, Sirs, yours faithfully,

Shrewsbury, Dec. 3rd, 1901.

H. WILLOUGHBY GARDNER.

## MR. HORSLEY'S ELECTIONEERING SPEECHES.

*To the Editors of THE LANCET.*

SIRS,—I have only to say in reply to Mr. Horsley's personal abuse of me, reported in your columns last week, that my letter on pp. 1374-75 of THE LANCET of Nov. 16th remains unanswered. Had Mr. Horsley's hands been clean it was open to him to refute the statements therein before the election, and especially the paragraph commencing: "I am much surprised at Mr. Horsley's attitude towards the sitting Direct Representatives." His lame defence before the Council proves that there was not a word of truth in his allegations against his colleagues, and particularly Mr. George Brown, against whom he now admits they were directed.<sup>1</sup> As to the rest, it can stand over until Mr. Horsley comes up for judgment before the constituency next year.

I am, Sirs, yours faithfully,

Liverpool, Dec. 7th, 1901.

ALEX. MCCOOK WEIR.

## A MEDICAL DEGREE FOR LONDON STUDENTS.

*To the Editors of THE LANCET.*

SIRS,—I beg to suggest that now is a most favourable opportunity for the London University and the Royal Colleges to formulate some scheme for the institution of a pass degree in medicine for London students. The exigencies of the situation are pressing. I submit that

<sup>1</sup> Vide Brit. Med. Jour., Nov. 23rd, p. 1544, and Dec. 7th, p. 1713.

future medical students will demand a pass degree as a reward for their labours. If this is not forthcoming they will not be induced to come to London. Generation after generation of medical students have hoped that something would be done by way of relief. Long-deferred hope is at present in a dying condition and approaching the end, and will be buried in the near future, hence the falling off in the entries at the metropolitan schools. As a result London will cease to be the great medical teaching centre, and the Royal Colleges will lose their position to a great extent as pass diploma-granting bodies within, say, the next 15 years. The plea that London has great clinical advantages will no longer act the siren and lure the student to London, as provincial universities with well-equipped laboratories and able staffs of teachers have been formed in populous manufacturing districts which offer clinical material to satisfy the most enthusiastic teacher and student.

I am, Sirs, yours faithfully,

FREDERICK W. COLLINGWOOD.

Wimpole-street, W., Dec. 8th, 1901.

## SMALL-POX AND VACCINATION.

To the Editors of THE LANCET.

SIRS,—All vaccinators are aware that many mothers object to vaccination in three or four places; consequently, if they can have their children vaccinated in one place only for sixpence they will not go to the public vaccinator for gratuitous vaccination in three or four places. There are medical men in South London who take advantage of this fact and do a considerable practice in sixpenny vaccinations. This cheap, and probably inefficient, sort of vaccination should be put a stop to, and I am surprised that any medical man can for a few pence consent to perform a most important duty in such a slovenly manner. If all vaccinations were efficient and successful the time would come when small-pox would attack the unvaccinated only and then the anti-vaccinationists would be silenced. I therefore recommend all with whom I have any influence to go to the public vaccinator who uses reliable lymph, vaccinates in three or four places, and has the skill which only large daily practice can give. If, as you say, there is better lymph than that prepared in the laboratory of the Local Government Board there is also much worse and some that is quite inert. A medical friend who is a most careful and skilful vaccinator got no results whatever from some lymph supplied by a certain firm, so instead of regarding his patients as "immune" (as too many would have done) he obtained some lymph from another firm, revaccinated all of them, and got most satisfactory results. I therefore agree with Dr. D. Nabarro who, in his letter in THE LANCET of Nov. 16th, p. 1371, said that "the Local Government Board ought to supervise the manufacture of the lymph supplied by the various firms or make arrangements whereby practitioners other than public vaccinators may obtain a reliable lymph. At present it is only by going to the public vaccinators that the public are certain of being treated with a potent lymph."

I am, Sirs, yours faithfully,

D. HOOPER, B.A., M.B. Lond.

Trinity-square, S.E., Dec. 7th, 1901.

To the Editors of THE LANCET.

SIRS,—There is but one way in which vaccination will become universal and all objections to public vaccinators' methods cease. When the present Act expires let a public vaccinator be appointed to do nothing else and after each vaccination inspection let him give the parent a paper guaranteeing to pay £10 if the child gets small-pox in 10 years. Years ago I wrote to you asking whether I should offend against ethics in doing so, and although you were good enough to state that my action would be correct I felt that it would arouse so much ill-feeling that I have never done it except to private patients. When a public vaccinator becomes a vaccinator and nothing else and has no possibility of having wrong motives applied to his actions, the general practitioner will encourage patients to go to the public vaccinator; it will not be worth while to do cheap "one mark" vaccinations and all the present friction will cease. It would be far cheaper to employ such a scheme, for each vaccinator—of which there could, at any rate in towns, be far less—would have a definite salary and a small capitation grant. I suppose there is no public vaccinator

who would not be willing to make the £10 guarantee part of his contract, for he could always refuse it when the vesicles were not satisfactory, and it is the only method that will convince the general public of the efficacy of vaccination.

I am, Sirs, yours faithfully,  
P. V.

Dec. 7th, 1901.

## THE DIRECTION OF HAIR ON THE HUMAN ARM.

To the Editors of THE LANCET.

SIRS,—The letter of Mr. G. Sherrington-Morris in THE LANCET of Dec. 7th, p. 1611, is both interesting and pertinent and, as far as it goes, bears out the view which I have sought to establish—viz., that use or habit may produce results which are inherited by offspring. The weak side of his communication from the point of view of inheritance is the failure to show whether or not these differences of hair-slope are found in infants. I may say that I happen to be at present investigating this very point as to the direction of the hair-slope on the arms of infants or very young children among these two sects of Mahomedans before the age at which the special ritual washings commence. The subject is being investigated for me by certain Mahomedans in India and I am hoping to make known the results of their observations as soon as they are received, whether they bear out my view or not. If very young children in these two sects of Mahomedans are shown to have no observable difference of hair-slope on their arms it may not prove much as to inheritance. But if a real difference exists in these young subjects the case will become a true *experimentum crucis* of a much-debated doctrine, and, I would add, in that case it will have the special value of being a small contribution to the statistical proof of the doctrine that acquired character can be inherited, because of the fact that the schism between these two sects occurred about the tenth century and the ceremonial acts referred to have been performed on the average five times a day by the individual Mahomedans according to their peculiar tenets. If I should obtain any definite results, I hope, Sirs, that you will be kind enough to allow me to publish them in due course.

I am, Sirs, yours faithfully,

WALTER KIDD.

Dec. 9th, 1901.

## EXCESS OF SALT IN THE DIET A PROBABLE FACTOR IN THE CAUSATION OF CANCER.

To the Editors of THE LANCET.

SIRS,—In reference to Dr. J. Braithwaite's paper read before the Leeds and West Riding Medico-Chirurgical Society<sup>1</sup> it may be worthy of remark that the mortality from cancer is high in Switzerland, and its increasing prevalence has already attracted observation. The consumption of salt in the country is very popular, and a salt flavour is considered essential in all savoury dishes, even by professed cooks. Bakers add salt to bread largely, sometimes in quantity sufficient to render it unpalatable to many persons not accustomed to the taste of it in bread. *Consommé* and soups are generally overloaded with salt, especially among the poorer classes of society. Salads and vegetables get a full share of it too. *Charcuterie* (sausages, ham, &c.) is cheap and is consumed freely. From personal observation I should consider the national appetite was exaggerated for salt as well as for sugar. In the consideration of cancer it may not be out of place to note that a considerable proportion of beef is furnished from old worn-out animals—cows unfit for the dairy or for traction and oxen no longer serviceable in harness.

I am, Sirs, yours faithfully,

Montreux, Switzerland, Dec. 7th, 1901.

TUCKER WISE.

## THE NEW GYNÆCOLOGICAL JOURNAL.

To the Editors of THE LANCET.

SIRS,—It is a pity that Messrs. Baillière, Tindall, and Cox did not, before issuing the prospectus of their new venture, take the trouble to ascertain the truth or otherwise before making the statement that "at present there is no

<sup>1</sup> THE LANCET, Dec. 7th, 1901, p. 1578.

journal devoted to the interests of British workers in obstetrics and gynaecology, and therefore they have recourse to the transactions of societies, hospital reports, and the general medical press in order to make known the results of their observations and researches."

The *British Gynaecological Journal* has now been in existence for 16 years. It is not merely the record of the proceedings of a society but is also "an exponent of contemporary thought and achievement in these branches of medicine and surgery throughout the world." The new journal will therefore be only copying a good example, and running on similar lines to the *British Gynaecological Journal*. It is a pity that instead of adding another journal to the large number already existing, the promoters of the new journal did not arrange to send their contributions to the old-standing journal and so help to make it still more, if possible, a representative publication of British gynaecology and obstetrics, more after the plan of the *American Gynaecological Journal*, instead of still further splitting up much useful information and trying to justify its appearance by making a misleading statement to its prospective subscribers.

I am, Sirs, yours faithfully,  
Harley-street, W., Jan. 8th, 1901.

HEYWOOD SMITH.

### MEDICAL OR LAY SECRETARIES TO HOSPITALS.

To the Editors of THE LANCET.

SIRS,—I ask permission to attempt to obtain the opinion of members of the medical profession through the medium of THE LANCET (or to myself privately) on the advantage or otherwise accruing to the public in appointing medical secretaries of hospitals, sanatoriums, and similar institutions (or of committees to organise their foundation) rather than lay officials. In such a question the spirit of the times may be read in recent appointments made in many professions, services, and public departments, at home and abroad, which attest the value of educated and specialised knowledge in such officials. Whether medical candidates for such posts could be obtained is another matter.

I am, Sirs, yours faithfully,  
20, Athenæum-street, Plymouth.  
Dec. 6th, 1901.

F. BUSHNELL.

### A SIMPLE APPARATUS FOR ETHER NARCOSIS.

To the Editors of THE LANCET.

SIRS,—It may interest the many medical men who have seen my ether inhaler in use to learn that I have received a letter and pamphlets from Dr. Longard of Aix-la-Chapelle from which I gather that the inhaler described in your issue of Nov. 9th, p. 1297, is the joint production of Dr. Longard himself and of Dr. Wagner.

In his letter Dr. Longard admits that there are several resemblances (*ähnlichkeiten*) between the Longard-Wagner inhaler and mine, and he then goes on to point out what he is pleased to call several essential differences. He states (1) that in the Longard-Wagner inhaler the ether reaches the absorbent surface through the funnel, while in mine the cover must be removed in order to let the anæsthetic gain access to the interior; (2) that in the Longard-Wagner inhaler there is only one inspiratory valve and that the absorbing material consists of gauze arranged between two metal sieves, while my inhaler is provided with two inspiratory valves; and (3) that in the Longard-Wagner inhaler the ether chamber is warmed by a "thermophor," while in mine the necessary heat is obtained by means of a hot-water jacket.

So much for the essential differences as enumerated by Dr. Longard. To me they seem most trifling variations in detail, and I feel therefore justified in maintaining that the Longard-Wagner inhaler is practically the same as that devised by me many years ago. That the two inhalers are identical to all intents and purposes may be seen by comparing the diagrams of my ether inhaler in THE LANCET of July 5th, 1884, p. 19, and of the Longard-Wagner ether inhaler in THE LANCET of Nov. 9th, 1901, p. 1297.

I do not assert that Dr. Longard and Dr. Wagner have derived the idea of their inhaler from previous acquaintance with mine, but the similarity between the two is, to say the

least, sufficiently remarkable to call for comment and to merit explanation.—I am, Sirs, yours faithfully,

P. BLAICKIE SMITH, M.D. Aberd.,  
Consulting Physician, late Physician and Lecturer on  
Clinical Medicine and Anæsthetist, to the  
Aberdeen Royal Infirmary.

San Remo, Italy, Dec. 2nd, 1901.

### MEDICAL BIBLIOGRAPHY.

To the Editors of THE LANCET.

SIRS,—With reference to the apprehended discontinuance of the *Bibliographia Medica* referred to in THE LANCET of Dec. 7th, p. 1611, the following quotation from the *Journal of Balneology and Climatology*, January, 1900, p. 68, may be useful: "From Paris, 93, Boulevard St. Germain, we have received a circular announcing that the work of the index will be carried on by a French firm under the name of *Bibliographia Medica*—sur le modèle de l'Index Medicus Américain—the first number is to appear immediately." There is, of course, the *Medical Review*, London.

I am, Sirs, yours faithfully,

CHARLES G. STUART-MENTEATH.

Upper Bedford-place, London, W.C., Dec. 9th, 1901.

\* \* The first number (that for January, 1900) of the *Bibliographia Medica* was noticed by our Paris Correspondent in THE LANCET of March 3rd, 1900, p. 660.—ED. L.

### THE ORGANISATION OF THE PROFESSION. (FROM OUR SPECIAL COMMISSIONER.)

*The Early History and Formation of the Birmingham and District General Medical Practitioners' Union.*

THE thoughtful student of history will not fail to observe that revolutions, especially the more successful revolutions, have originated from the higher classes and not, as is too hastily supposed, from the lower classes. It is when the pinch is felt by at least a section of the governing classes that the situation becomes dangerous. The great French revolution was in a large measure the work of the encyclopædists who belonged to the best educated classes and were patronised by a considerable section of the aristocracy, while such men as Mirabeau and St. Just were members of the nobility. So also in smaller movements the same rule applies, and has yet again been demonstrated by recent occurrences at Birmingham. Here the medical profession were in a deplorable position. The grievances denounced under the heading of "The Battle of the Clubs"<sup>1</sup> and of "Hospital Abuse"<sup>2</sup> set forth the details of the prevalent unfair competition, the spread of abuse under the mantle of pretended charity, and the sweating of members of the profession by lay speculators. These articles also pointed out how the marvellous success and skill shown in organising the Hospital Saturday Fund had brought into existence a power stronger than that of the trade unions which might largely control the management of the hospital and other charities and seriously interfere with the interests and position of the members of the medical profession. On the other hand, there was little or nothing to indicate the existence of any countervailing force capable of holding in check these menacing developments. What few efforts had been made at organisation by the medical men of Birmingham had rapidly collapsed without bearing any fruit. Indeed, the despondent tone of many of the local practitioners and consultants with whom I discussed these questions at the time led me to conclude that there were special psychological influences in Birmingham which rendered the work of organising the medical profession more difficult there than in many other towns and centres. Now that it is proposed by the British Medical Association to organise its members everywhere throughout the kingdom on the same basis, it becomes of increasing and of practical importance to observe how the difficulties and facilities vary from

<sup>1</sup> See THE LANCET, Jan. 4th (p. 69) and 18th (p. 199), 1896.

<sup>2</sup> See THE LANCET, July 31st (p. 284), August 14th (p. 415), and Sept. 4th (p. 622) and 18th (p. 745), 1897.

place to place. In respect to organisation, Birmingham presented, it seemed to me, the same disadvantages as does a new and prosperous colony. It was peopled to a large extent by men who had rushed in from the outside, who had no local ties, who did not desire to make the town their permanent home, or who came exclusively for the sake of higher wages and better monetary prospects. Where there is an abnormal rush for wealth the work of organisation is always difficult, and, as a case in point, trade unionism is much weaker in the United States of America than in England; it is likewise weaker in Birmingham than in other parts of the kingdom where the local industries have developed in a more stable manner. Or, to give a wider example, the rapid growth of modern industrialism and commercialism throughout Europe broke up the ancient guilds. These considerations led me to say<sup>3</sup>: "Among such a population it is difficult to spread altruistic ideas; it is a wild endeavour all round after business each for himself, and but few pause to consider what are their duties to society. This spirit also animates more or less—let us hope very much less—the medical profession and therefore it has been more particularly difficult to group the medical men together and to get them to put their personal interest in the background so as to defend the position of the profession as a whole." The remarks gave offence at the time to a prominent member of the profession practising in Birmingham, but the only argument that he adduced really tended to prove my contention. He urged that such great public spirit had been shown by the inhabitants that Birmingham had acquired the reputation of being the best governed city in the world. Undoubtedly the municipality of Birmingham has been induced by its electors to take the initiative in respect to several very important public enterprises. It will, however, be noticed that wherever voluntary organisation is weak there will be found the loudest demands for State or municipal interference. The workers of England, as compared with the workers of the continent, have been the last to demand State interference in regard to their economic conditions; but then they possess the strongest and best organised trade unions. On the other hand, the members of the medical profession are as yet but feebly organised, and therefore on all sides it is urged that the General Medical Council should interfere or that the law should be enlarged so as better to protect the profession. In these economic questions medical men are not different from other classes of the community. The lessons of history apply to them as to other mortals, and they must likewise yield in some degree to the social influences by which they are surrounded. It is very certain that medical men after a prolonged residence in such towns as Eastbourne or Yarmouth will have ideas different from those entertained by practitioners who have lived in centres of commercial and manufacturing enterprise such as Glasgow or Birmingham. It should be possible to study and to record such differences without giving offence to anyone.

Fortunately, within the last two years so great a change has taken place in Birmingham that it may be qualified as being, in its way, quite a little revolution. Though insisting that the economic conditions prevailing in Birmingham were not favourable to the work of organisation, I nevertheless gave a very lengthy account of the widespread and skilful organisation of the Hospital Saturday Fund. In this I did lay myself open to a charge of inconsistency, but my critic failed to see this point. The explanation of such a contradiction rests on the fact brought forward in my opening remarks that revolutions often come from a class above that mainly affected. It was not the people concerned, it was not the poor and the working classes who organised the Hospital Saturday Fund. Its present success is due mainly to the eloquence, indomitable energy, and consummate organising capacity, not of a workman, but of Mr. Smedley, who is an accountant. Alderman Cook and other gentlemen and business men have also helped in the task, and what the workmen are now able to do for themselves is due to the teaching which they received from those who stepped out of a higher class to help them. The Hospital Saturday Fund, which started in 1874, was at first merely a collection made principally among working-men on a certain day in the year. During the first years the sums raised varied from a little more than £3000 to a little less than £5000. It was not till

after 1885, and when Mr. Smedley appeared on the field, that the whole system of collection was altered and so extended that five years later, in 1891, the amount collected had more than doubled, and was equal to £11,000. The collection made on Hospital Saturday represents but a small fraction of the total sum obtained, which now exceeds £18,000. This is gathered in by penny weekly collections enforced by social and moral pressure in nearly all the factories and workshops of Birmingham. When I wrote last on the subject I pointed out that in 1895 the medical charities, the hospitals of Birmingham, had a yearly income of about £45,000 including the £10,000 given by the Hospital Saturday Fund, and that, with the balance remaining, this fund had already organised convalescent homes and nursing institutes of its own. It then occurred to me that if the Hospital Saturday Fund were to withdraw its support the hospitals would be on the verge of bankruptcy. Circumstances might arise which would lead the managers of this fund to prefer to establish hospitals of their own, under their exclusive management, with a paid staff, just as they had already successfully done with regard to their own convalescent homes. The existing hospitals would then be in sore difficulties and to prevent such a contingency many concessions had to be made.

This, however, has not yet been attempted, but the proposed creation of the Consultative Institute was a step in this direction. Not content with possessing its own convalescent homes and its own trained nurses the committee of the Hospital Saturday Fund determined to have its own staff of consultants. Again this was a movement that did not spring from the workmen but from a class above them. It was not the suggestion of the workman; it was a proposal originally made by Mr. Arthur Chamberlain. This gentleman, who is a wealthy local manufacturer and company director, was one of the leading members on the committee of management of the Women's Hospital. Nor does he seem in this matter to have been at first particularly concerned about the working classes and the poor generally. On the contrary, he had for a long time been using his best endeavours to persuade the staff of the Women's Hospital to give advice to a better class of patients. Anxious, perhaps, to increase the income of the hospital he proposed that the better class of patients should be charged a fee of 5s. and that half of this sum should be paid to the medical staff and the other half reserved to help in covering the working expenses of the hospital. But to the honour of the medical staff it must be recorded that they repudiated this essentially commercial proposal. They were not willing to be thus employed as instruments for competing against their brothers in the profession. The hospital to them remained a charitable institution and not a commercial enterprise. It was after the failure of this scheme that Mr. Arthur Chamberlain addressed himself to the committee of the Hospital Saturday Fund and urged that they should form a consultative institute. So great, apparently, was Mr. Arthur Chamberlain's desire to bring the members of the profession, and especially the consultants, under the thralldom of commercial laws and methods that he even offered to be personally responsible for half the financial loss if the enterprise failed to pay its expenses. The idea was that a staff of consultants should be appointed as the servants of the institute at a salary of £500 per annum. The outlay was to be met by half-guinea fees which the patients were to pay, not to the medical men, but to the institute for each consultation. Of course, if such an institute possessed a competent medical staff private consultants would lose many of their patients who actually paid their guinea fees and could well afford to do so.

Thus, most fortunately for the interests of the profession at large, a blow was aimed not, in this instance, at the poor and underpaid general practitioner, but at the highest, most prosperous, and best paid medical men. The great difficulty in the work of organisation has been due to the indifference and the ignorance of the more prosperous medical men, and notably of the consultants. They often do not know or have forgotten what the poorer general practitioners have to endure. The battle of the clubs does not affect them because they have no club patients. They likewise are not deeply concerned in the abuse of hospitals, for if sufferers go there who can pay 1s. 6d. or 2s. 6d. in fees these are not the class of patients whom the consulting physicians or surgeons of the hospitals are in the habit of attending. Therefore the economic difficulties that beset the

<sup>3</sup> See THE LANCET, July 31st, 1897, p. 284.

majority of the profession do not affect the few who are exceptionally prosperous. Consequently, the latter have no personal need of joining militant medical unions formed to deal with these economic problems, and this has always been one of the greatest obstacles in the way of the organisation of the profession. Here, however, in Birmingham the interference of Mr. Arthur Chamberlain has most happily removed this very serious stumbling-block. He has provided a grievance where no grievance existed, and thus has brought into line the very men who were the most difficult to move. There were about 50 medical men in Birmingham who claimed to be consultants or specialists, and they at once determined to make a stand against the formation of the proposed Consultative Institute. They met together, they appealed to the Lord Mayor to intercede between them and the Hospital Saturday Fund Committee, and they explained that they were themselves quite willing to give advice for half a guinea to poor persons who could not afford to pay more. Indeed, this was already a very usual practice; therefore there was no need of a consultative institute unless to obtain advice at a cheaper rate for those who could afford the guinea fee and to convert independent medical men into the paid servants of an institute managed by a lay committee. But in taking such action the consultants felt that they needed the support of the whole profession. Therefore they summoned a general meeting at which it was decided that anyone who accepted service in the pay of the Consultative Institute should be boycotted by the whole profession. Thus brought together, however, the medical practitioners of Birmingham were not content to discuss merely the question of the Consultative Institute. This was a grievance which concerned more especially the consultants, but the general practitioners had grievances of their own just as urgent and far more numerous. They were quite ready to act in union to defend the interests of the consultants, but they also, and very naturally, desired to employ the force thus acquired in defence of their own interests. Hence it came about that a proposal was made to found a permanent medical union dealing with all questions affecting the economic and ethical interests of the profession. The first meeting—a comparatively small one—was held at the Victoria Hall, Aston, and it was then resolved to summon all the general practitioners within a radius of five miles to meet at the Grand Hotel, Birmingham, so as to decide whether a union should be established. About 100 practitioners attended this second meeting. The proceedings were throughout most enthusiastic, and it was then resolved to form the Birmingham and District General Practitioners' Union. A committee was elected to draft rules and as a result the new society was formally constituted on Oct. 1st, 1899. The second annual meeting held by this union has already been described\* and it was then stated that it numbered 253 members. The work of organisation has, therefore, at last proved successful even in Birmingham. To me, who saw and described four and five years ago the state of disunion and chaos that then prevailed in the ranks of the profession, this great change appears in the light of a small revolution. But, as I remarked in my opening observations, it is a revolution that originates from the higher ranks of the profession. It was not till the consultants had put their shoulders to the wheel and given the necessary impetus that the movement gathered strength and became really successful. The dual principle, action and reaction, finds in these events another illustration of its truth. But for Mr. Arthur Chamberlain's interference in the affairs of the medical profession the state of disunion prevailing in its ranks might have continued to this day. The action which he took on one side produced reaction on the other side, and thus the Birmingham and District General Medical Practitioners' Union has been called into being.

(To be continued.)

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

### *Another Liverpool Expedition to West Africa for the Study of Malaria.*

Dr. Charles Balfour Stewart sailed from Liverpool for West Africa on Nov. 30th, under the auspices of the Liverpool School of Tropical Medicine, to investigate further

the causes of malaria. He will proceed at the outset to Sierra Leone, in order to study the methods at present adopted there with such success by Dr. Logan Taylor. He will first attack the disease in the town of Cape Coast Castle, where there is now a considerable mortality amongst Europeans. He will have full charge, under Major R. Ross's directions, of the operations on the Gold Coast. The *modus operandi* will be that of drainage of the ground and clearing out broken vessels which may hold water by means of large gangs of native workmen, as is done in Freetown, and by other means to effect sanitary improvements. Dr. Stewart has been engaged by the Liverpool School for one year, but he will probably remain as long as his services are needed to carry on the important work on the Gold Coast. The health conditions of the gold-mines will be a further object of his attention, as the school authorities have instructed him to visit the mining districts where possible. His movements, however, will be largely determined by the wishes of the Governor of the Gold Coast. Efforts for the eradication of malaria will thus shortly be general all along the West Coast of Africa from Gambia to Lagos, three of these colonies, Gambia, Sierra Leone, and the Gold Coast, being dealt with by the Liverpool School of Tropical Medicine. Dr. Stewart has done important work in India in the matter of plague. He also acted as assistant to M. Haffkine at the malarial research laboratory at Bombay.

### *The Proposed Fellowship for the Promotion of Physical Research at University College, Liverpool.*

Mrs. George Holt and Miss Holt have generously made the offer to the council of University College to found a Fellowship to promote research in physics to be associated with the name of Dr. Oliver Lodge, the late Professor of Physics at the College, in commemoration of his services to the College, to the city, and to science. The Fellowship will be tenable for one year, re-election being allowed, but it may not be held by one person for more than three years in all. Its annual value will be £100. or more. A prize to be called the "Oliver Lodge Prize" has also been established by Dr. Lodge's friends and late colleagues, to be awarded annually to the best student in physics in the third year of the honours course. Both offers have been gratefully accepted by the council. Detailed plans and specifications for a new laboratory for the department of physics, now in charge of Professor Wilberforce, will be shortly placed before the council of the college for their approval.

### *Memorial to the late Sir Henry Tate, Bart.*

The Dowager Lady Tate has given a donation of £1000, in memory of her late husband, Sir Henry Tate of Liverpool, to the Queen Victoria Jubilee Institute for Nurses, to be added to the sum given by her late husband which is used for the benefit of the Queen's nurses themselves in times of sickness.

### *Liverpool Boards of Guardians and Epileptic Patients: Proposed Conference.*

Provision for the proper accommodation of sane epileptics is urgently required at the three Liverpool workhouses, present conditions being altogether inadequate and unsuited to the treatment of that class of patients. The matter has been the subject of frequent discussions of late at the three boards of guardians of Liverpool, Toxteth, and West Derby. The Blackburn Union have addressed a communication to the three boards of guardians, asking them to send representatives to a conference of Lancashire unions to be held, if possible, in Blackburn, to discuss the entire question. The Liverpool Select Vestry and the Toxteth Board of Guardians have decided to agree to the request. I have not been able to discover the intentions of the West Derby Board in the matter.

### *The Lancashire Asylums Board.*

At the recent annual meeting of the Lancashire Asylums Board held in the County Hall, Preston, the chairman (Alderman W. S. Barrett) moved the adoption of the report of the deputation appointed to wait on the Commissioners in Lunacy with reference to the board's agreement that the Winwick Asylum should be wholly devoted to chronic cases and filled exclusively by transfer from the other asylums. The report stated that the deputation urged that chronic cases should be allowed to be sent direct to Winwick Asylum from workhouses or their own homes, thus avoiding the expense of first sending them to one of the other

\* THE LANCET, Nov. 30th, 1901, p. 1536.

asylums. The Commissioners, however, contended that if chronic patients were received into Winwick Asylum direct advantage would be taken to send patients other than chronic and for whom there was no proper accommodation, thus placing the medical superintendent in the invidious position of having to decline to admit them. That being so, they could not see their way to alter the original agreement.—Mr. H. R. Ley, the medical superintendent at Prestwich Asylum, has resigned owing to failing health.—Mr. F. Perceval, the medical superintendent at Whittingham Asylum, has been transferred to Rainhill.

#### *The Dangers of Wearing Flannelette.*

Presumably on account of the alarming number of recent deaths of children in Liverpool owing to the ignition of flannelette garments, the Watch Committee have received a communication from the Home Office calling attention to the frequent fatal burning cases which took place in the city through the ignition of young children's clothing. The matter was referred to the Fire Police Sub-Committee for consideration.

Dec. 10th.

### WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

#### *Isolation Accommodation in Herefordshire.*

THE special industries of Herefordshire—hop-growing and fruit-culture—attract to the county during two or three months in each year several thousands of the poorer classes from the populous towns in the neighbouring counties of Staffordshire and Warwickshire. The risk of infectious diseases being introduced is therefore very much greater than in rural districts where no such immigration takes place. In the whole of Herefordshire only one sanitary authority has deemed it necessary to provide a permanent isolation hospital, and the county council has taken no steps, as it is empowered to do by the Isolation Hospitals Act, 1893, in the direction of ascertaining whether sufficient isolation accommodation exists in the county. On Dec. 7th a discussion took place at a meeting of the Hereford Rural District Council upon a proposal which was made by the chairman of the board of guardians to establish three cottages in different parts of the district into which infectious cases could be removed. The novelty of the scheme lay in the suggestion that when the nurses, who would live in the cottages, were not occupied with nursing cases of infectious disease their services should be available either as district nurses or as workhouse nurses. It is to be regretted that the proposal was not accepted, and a very heavy responsibility will rest upon those members of the council who opposed it if they do not assist in some way in providing means for isolating infected persons in the district.

#### *Swansea General Hospital.*

The board of management of the Swansea General Hospital decided on Dec. 4th to erect a second theatre for minor operations at a cost of £200. Further alterations, which it is estimated will cost £1300, were also resolved upon. These include two isolation wards, additions to the nurses' home, a rearrangement of the dispensary, and a detached out-patient department having two consulting-rooms, three dressing-rooms, a nurses' room, and a waiting-room to accommodate 100 persons.

#### *Colwyn Isolation Hospital.*

The Colwyn Bay Urban District Council has decided to erect an isolation hospital at a cost of £5700. The buildings will include a separate administrative block and two ward pavilions having a total accommodation for 16 patients.

#### *Cardiff Water-supply.*

Nearly the whole of the water for the supply of Cardiff and Penarth is obtained from the Breconshire hills and the decreased rainfall on the gathering grounds during the present year has materially diminished the amount of water in the reservoirs. In November a rainfall of only four inches was recorded, or exactly one-half of that recorded during November, 1900. The total storage capacity amounts to 1,000,000,000 gallons, and in May of this year there were in the four reservoirs 970,000,000 gallons, an amount which was reduced by Dec. 1st to 796,000,000 gallons. The total daily consumption averages 5,000,000 gallons, equal to about 27 gallons per head of the population. Although Cardiff is

practically a town provided with water-closets, there are a large number of houses without a flushing apparatus.

#### *Water-supply of Glamorganshire.*

The Sanitary Committee of the Glamorgan County Council has instructed the county medical officer of health to report in June next upon the water-supplies of the county. The only complete report hitherto made has reference to the Rhondda district, where there is a population one-fifth that of the whole county, and was compiled by the medical officer of health for that district. In some of the colliery districts the supply is lessened owing to the subsidences which have taken place through the working of the mines, so that gathering grounds which formerly produced large quantities of water are now of comparatively little value.

Dec. 10th.

### SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

#### *The Victoria Infirmary, Glasgow.*

THE annual report of the governors of the Victoria Infirmary, which was issued on Dec. 3rd, gives satisfactory evidence of the activity and efficiency of the institution. The only qualification is provided by the balance-sheet, which shows a deficit for the year amounting to over £3500. To meet this it has been necessary to draw upon legacies and other sums which belong more properly to the capital account. The year has been marked by the erection of a new pavilion which provides several small wards for isolation purposes, two additional operating-rooms, a laboratory, and a room for the treatment of skin diseases by the Finsen and other allied forms of treatment. The expense of the appliances for this last-mentioned purpose, as well as the provision of a complete installation of a Roentgen-ray apparatus, has been undertaken by Mr. Archibald Walker, a member of the committee of management. The governors draw attention to the fact that the requests for admission to the hospital continue to be far in advance of the accommodation afforded, the numbers waiting for admission frequently reaching the total of 100. In these circumstances they express the opinion that the extension of the hospital must soon be undertaken. The building of a new wing will cost, it is estimated, from £25,000 to £30,000, and an appeal for this sum will shortly be made to the public. A further expense which cannot long be avoided is the provision of a new out-patient department, the demand for which is becoming increasingly urgent. At the annual meeting on the motion of the Lord Provost the report was adopted. A new feature of the management was provided by the election of two ladies to the governing board. This point at one time threatened to produce some degree of controversy, but in the end unanimity was secured and the ladies were appointed with enthusiasm.

#### *Glasgow Royal Infirmary.*

It is announced that, thanks to the generosity of a few gentlemen, the Royal Infirmary has been presented with a new and complete installation of medical and surgical electrical apparatus. The equipment of the hospital in this direction has for some time been well above the average, mainly owing to the special interest taken in the department by one or two members of the staff. The new installation will include arrangements for obtaining both high-potential and high-frequency currents as well as apparatus necessary for the treatment of lupus by various forms of light rays. Finsen's method has been for some time in operation at the hospital and both it and the x-ray and other electrical methods are to be presented in their most modern form. The whole installation has been arranged so that it can be transferred to the new hospital whenever that building is ready for its reception. The office of superintendent to the infirmary is advertised as about to become vacant. The salary is to be £500 per annum, with board and free house, coals, and light.

#### *Glasgow New Small-pox Hospital.*

The proposal to erect a new small-pox hospital at Lethanmill appears likely to lead to some controversy. At a recent meeting of the district committee of the Lanark County Council it was pointed out that the site of the hospital was in close proximity to the reservoir from which a large district, involving some of the Glasgow suburbs,

receives its water-supply. During the discussion some very energetic phrases were applied to the corporation's proposal, and it was agreed to communicate to the Local Government Board an expression of the committee's disapproval of the selected site.

Dec. 10th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

*The late Mr. William Smyth, L.R.C.S. Irel., of Burton Port.*

THE melancholy death of Mr. W. Smyth of Burton Port and Arranmore Island from typhus fever has given rise to a feeling of admiration for his heroism and of widespread sympathy with his family, left poorer by his loss. While conveying some fever-stricken patients in an open boat over the four miles which separate the island from the hospital on the mainland Mr. Smyth contracted typhus fever from which he died. A subscription list, headed by the Presidents of the Royal College of Physicians of Ireland and the Royal College of Surgeons in Ireland, has been opened and many donations have already been received. Letters of sympathy, with subscriptions, have also just been received from His Excellency the Lord Lieutenant, His Eminence Cardinal Logue, and His Grace the Duke of Abercorn. A sum of over £400 has already been subscribed in Belfast.

*Honours to the Irish Hospital Corps.*

On Dec. 7th his Excellency the Lord Lieutenant formally presented medals to the Irish Hospital Corps who have recently returned from South Africa. The members of the corps assembled in the Upper Castle Yard, under the command of Sir William Thomson, their surgeon-in-chief. The Lord Lieutenant, who was accompanied by the Duke of Connaught and Lady Cadogan, delivered an interesting address in which he highly praised the staff of the hospital and the work which they had accomplished at the seat of war, expressing at the same time his regret at the unavoidable absence of Lord Iveagh, to whose magnanimity and benevolence the organisation of the hospital was entirely due. His Excellency took the opportunity of calling attention to the brilliant services of the late Sir William MacCormac during the time of war and alluded pathetically to the self-denying work recently performed in Ireland by Mr. William Smyth of Donegal "who met his death the other day under such painful and yet under such glorious circumstances." Sir William Thomson, in reply, thanked his Excellency on the part of all the members of the corps, and conveyed the apology of Lord Iveagh for his quite unavoidable absence. The members of the surgical and medical staff who received decorations were: Sir William Thomson, Mr. G. Stoker, Dr. Coleman, Dr. Friel, and Dr. Thomas Edwards.

*The Ulster Medical Society.*

The second public meeting of the session 1901-1902 was held in the Belfast Museum on Dec. 5th, the President, Professor W. Whitla, M.D., occupying the chair.—Dr. W. B. McQuitty showed two patients suffering from Myxœdema and gave details of three cases illustrated by photographs showing their condition before and during treatment.—Dr. A. Fullerton read notes of a case, illustrated with photographs, of a child with Penile Hypospadias and Cleft Scrotum and discussed the surgical treatment.—Professor J. L. Smith and Dr. J. S. Darling showed the Kidneys and Bladder from a case of Enlarged Prostate.—Dr. V. G. L. Fielden showed an apparatus for the Continued Administration of Nitrous Oxide and Oxygen.—Dr. T. S. Kirk described a Modification of Thiersch's Method of Skin-grafting.—Dr. Charles O'Neill read a paper, illustrated with lantern slides, on the Biological Purification of Sewage.—In the discussions on these communications the following took part: the President, Dr. A. B. Mitchell, Professor J. W. Byers, Dr. W. Calwell, Dr. A. Dempsey, Dr. J. Rusk, and Dr. H. O'Neill.

*The Royal Victoria Hospital, Belfast.*

The shareholders of the Oceanic Steamship Co. (better known as the "White Star" line) have decided to honour the memory of Mr. T. H. Ismay, the late chief of the line, by giving £10,000 to the Liverpool Seamen's Pension Fund (which was established by Mr. Ismay in 1887), and also by giving £10,000 towards the endowment of a ward in the Royal Victoria Hospital, Belfast, to be called the "Thomas

Henry Ismay Ward." By these two munificent gifts the connexion of the "White Star" line with Liverpool (where the head offices of the company are located) and with Belfast (where, in the great yard of Hartland and Wolff, the ships of the line were built) is emphasised. Shortly before his death Mr. Ismay was made an honorary freeman of Belfast.

*Queen's College, Belfast.*

Professor J. Symington has been appointed registrar of Queen's College, Belfast, in place of Professor J. M. Purser, resigned.

*Belfast District Lunatic Asylum.*

In his report as inspector of asylums Sir G. P. O'Farrell points out that at the day of his visit there were 713 patients at Belfast, 150 at Purdysburn, and 62 at Ballymena; and inasmuch as the old asylum only provided legitimate accommodation for 440 patients it would be evident how greatly overcrowded the institution was, and it was only by the excellent administrative arrangements and by keeping the patients as much as possible in the open air that this serious overcrowding had not prejudicially affected the health of the inmates. The committee had arranged to meet this overcrowding to some extent by building two villas on the Purdysburn estate. Sir G. P. O'Farrell says that he was pleased to find every part of the asylum clean and orderly. The dietary was satisfactory and suitable to the needs of the patients, and the amusement of the patients continued to receive due attention. Dr. R. A. L. Graham, the junior assistant medical officer, continued to take great interest in pathological work. The medical books were carefully kept and the general management of the asylum, the inspector reports, bore distinct evidence of the zeal and ability of the medical superintendent (Dr. W. Graham) in the discharge of his duties.

*The late Sir William MacCormac.*

The greatest sorrow was felt in Belfast on Dec. 4th, when the very sudden death at Bath of Sir William MacCormac was announced. His close connexion with Belfast was brought out in your full obituary notice.—At a meeting of the Ulster Medical Society held on Dec. 5th, on the motion of Professor Byers, seconded by Dr. Dempsey, the following vote of condolence was passed in silence and ordered to be entered on the minutes of the society and a copy to be sent to Lady MacCormac:—

That the members of the Ulster Medical Society desire to take this the earliest opportunity of expressing their great regret at the loss they have sustained through the sudden death of Sir William MacCormac, Bart. Originally an ordinary, and afterwards an honorary, member of the Ulster Medical Society, he took the deepest interest in its affairs and the members have followed with pleasure and pride the successive stages of his brilliant career since he left Belfast. The son of a distinguished Belfast medical man, Sir William MacCormac always maintained the highest traditions of the profession. The members of the Ulster Medical Society wish to express their sincere sympathy with Lady MacCormac in her present deep trial.

At a meeting of the board of management of the Royal Victoria Hospital held on Dec. 7th, on the motion of the Chairman (Mr. William Crawford), seconded by Professor Byers, a vote of condolence was passed with Lady MacCormac on the death of her distinguished husband who had been house surgeon, surgeon, and consulting surgeon at various times to that institution.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

*Reports upon Epidemic Diseases.*

AT the meeting of the Academy of Medicine held on Nov. 26th M. Landouzy read the report of the commission upon epidemic diseases. The report laid great stress upon the absolute incompleteness of the returns furnished by the various prefects. The figures which are given as to the different contagious diseases, in conformity with the law of 1892, are very incomplete, and most of the reports give no statistics either as to the incidence of a disease or its fatality. Influenza is responsible for a large number of deaths by reason of complications involving suppurative affections. Cerebro-spinal meningitis is fairly common, but small-pox is rare and almost unknown in certain districts, as for instance Bordeaux, where vaccination is rigorously carried out. Wandering pedlars have imported this disease into certain districts and

M. Landouzy maintained that vaccination and revaccination should be carried out in the case of such persons. The death-rate from diphtheria has fallen considerably, thanks to the very early use of Roux's serum. A certain number of cases of typhoid fever are put down to infection by the inhalation of dust. The report further draws attention to the necessity for distributing information as to general and personal hygiene in all scholastic establishments. The report also asks for the creation of a sanitary inquiry into the health of both the civil and the military sections of the community. Information on these points is much wanted to prevent the spread of disease by patients who leave the hospitals before they are completely cured. For instance, when a tuberculous patient is allowed to return home his family ought to be told of the various measures necessary to prevent him from becoming a focus for the spread of the disease. Three very interesting reports were sent in by Dr. Kermorgan, Inspector-General of the Colonial Medical Service. One dealt with yellow fever in Senegal, one with tuberculosis in the colonies, and the third with infectious disease in the colonies.

#### *The Physiological Effects of Balloon Ascents.*

At the meeting held on Nov. 25th M. Gaule laid before the Academy of Sciences the result of some researches which had been undertaken by himself with a view to ascertain whether the results of a balloon ascent were comparable with those obtained at a high altitude on land—e.g., at the top of a mountain. The most notable of these is a marked augmentation in the number of red corpuscles. Viaux and sundry observers who followed him have ascertained that at a high altitude there is a great increase in the number of red corpuscles. Thus in the Cordilleras at a height of 4000 metres, Viaux found 8,000,000 red corpuscles per cubic millimetre. M. Gaule wished to see whether in a balloon ascent, where ascension is very rapid and entails no muscular exertion, a similar phenomenon would occur. He made two investigations at heights of 4200 and 4700 metres and found in himself 8,000,000 red corpuscles per cubic millimetre. Further, M. Gaule at a height of over 4000 metres made some blood-films stained after Ehrlich's method with eosin and hæmatoxylin. He found numerous red corpuscles which showed a nucleus coloured blue by the hæmatoxylin. This nucleus was in many instances segmenting, and also groups of three or four corpuscles were seen as if they had undergone subdivisions. Similar preparations made before the ascent showed no such appearances. M. Gaule therefore considers that at high altitudes there is an actual formation of red corpuscles and that this takes place with great rapidity. At the following meeting M. Tissot and M. Haillon gave an account of researches on a somewhat analogous subject. On Nov. 21st they undertook some researches at various altitudes into the physics and chemistry of the respiration. Experiments were made at the following heights: 1350 metres, 2600 metres, and 4450 metres in the case of M. Tissot, and at 1700 metres and 3500 metres in the case of M. Haillon. The chemical phenomena of the respiration did not vary appreciably at these different altitudes. The respiratory rhythm, however, was greatly modified. Although the total quantity of air entering the lungs was less the number of respirations was not sensibly altered. It would thus appear that at high altitudes the air is purer and more completely used.

#### *The Fatal Accident at the Lariboisière Hospital.*

I have already acquainted your readers<sup>1</sup> with the details of the fatal accident at the Lariboisière Hospital, owing to the mistake of a nurse who administered chloride of zinc as an enema. The court of first instance has sentenced the matron of the hospital to two months' imprisonment and the director of the hospital to 15 days' imprisonment as being responsible for the accident, with right of appeal in both cases. The nurse was given three months' imprisonment, also with right of appeal, but she accepted the sentence. The ninth division of the Court of Appeal, before which came the cases of the matron and the director, has just delivered judgment. The nurse alone was considered guilty. The judgment stated that the vessel from which the nurse drew the fluid employed for the enema was labeled "chloride of zinc" sufficiently legibly for the court to read it, and that the error was that of the nurse alone. The matron and the director were acquitted.

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

### *The Agglutination of Tubercle Bacilli and its Diagnostic Value.*

At a meeting of medical officers of consumption hospitals Professor Koch recently read a paper on the Agglutination of Tubercle Bacilli and its Diagnostic Value. In this paper, which has been published in the *Deutsche Medicinische Wochenschrift*, he said that cultures of the bacilli of enteric fever, cholera, and bubonic plague agglutinated by the addition of blood serum of patients suffering from these diseases and that this fact was of great diagnostic importance. Dr. Arloing and Dr. Courmont had described a method of causing tubercle bacilli to become agglutinated, provided that they had been cultivated on potatoes, but their method had not proved to be trustworthy. Professor Koch therefore proceeded in another way, of which the following is an outline. The essential is that weighed quantities of pulverised cultures of tubercle bacilli are mixed with a solution containing 0.5 per cent. of carbolic acid and 0.85 per cent. of sodium chloride and then diluted with the same fluid to 1000 times the weight of the dry culture. This test fluid is agglutinated only by the serum of a tuberculous animal, the serum of non-tuberculous animals having no influence on it. The agglutination is especially marked when one part of serum is mixed with nine parts of test-fluid, but is perceptible when one part of serum is mixed with 150 parts of test-fluid. Professor Koch then examined the blood serum of different species of animals. He found that in 28 normal rabbits out of 30 the serum had no agglutinating action; the same was the case in goats, asses, dogs, and cattle, with which in only very few instances did agglutination take place. The blood serum of horses, 10 of which were examined, showed considerable spontaneous agglutinating power in mixtures of one part of serum with 25 and even with 50 parts of test-fluid. He then experimented on the artificial increase of the agglutinating power of the blood serum. The serum of goats which had been injected subcutaneously with cultures of tubercle bacilli showed after a few injections agglutination when the proportions of serum and test fluid were 1 to 50 and even 1 to 100; with rabbits the proportions varied between 1 to 100 and 1 to 400; and with horses the proportions were 1 to 200. Professor Koch said that he had reason to believe that animals in which the agglutinating action was increased by injections of tubercle bacilli were at the same time immunised; so that the degree of the agglutination corresponded to the degree of the immunity obtained. The experiments on this subject were, however, not yet finished. He then injected serum of high agglutinating power into tuberculous patients in the hope of obtaining a curative effect, but hitherto without any satisfactory result. He found that the serum was unable to agglutinate the bacilli of diphtheria, enteric fever, and bubonic plague, but that the bacilli of *perlsucht*, tuberculosis of fowls and of fishes, and butter bacilli, which when stained showed the same resistance to acids as tubercle bacilli, were agglutinated by it. Conversely, when animals were immunised by injections of this kind of bacilli their serum was able to agglutinate the bacilli of human tuberculosis. Professor Koch then examined the blood serum of tuberculous and non-tuberculous persons. Among 30 non-tuberculous persons there were five whose serum had an agglutinating power; among 78 consumptives there were five whose serum caused agglutination when mixed with test-fluid in proportions of 1 to 50 or 1 to 25, and there were 14 whose serum acted similarly when the proportions were 1 to 10. There was, in fact, no very marked difference between the serum of both categories and the method was therefore of no use for the diagnosis of tuberculosis. Attention was then drawn to the fact that in the advanced stages of tuberculosis the agglutinating action did not increase, as was the case in plague, enteric fever, and cholera. The cause was, in his opinion, that in the latter diseases substances (alexins) were produced in the blood which conferred immunity to subsequent attacks and that it was owing to the alexins that the agglutination of the bacilli took place. In tuberculosis such substances were not present (an infection by tuberculous virus predisposed to subsequent attacks of tuberculosis) and agglutination therefore did not occur. Professor Koch some years ago, as

mentioned in THE LANCET of April 10th, 1897, p. 1057, described a method of obtaining a certain degree of immunisation, and he employed a modification of this method for the purpose of seeing whether the agglutination was thereby increased in tuberculous patients. In the modified method recently adopted the whole quantity of a pulverised culture of tubercle bacilli was injected and the amount injected must be sufficiently large to produce a rise of temperature of from 1° to 2° C., just as with the old tuberculin of 1890. The injections were then repeated at intervals of from six to eight days and the amount injected was increased till it reached from 20 to 30 milligrammes. The result was that the agglutinating power of the serum was considerably increased in this way but that it decreased when a smaller quantity of bacterial culture was injected. If, notwithstanding the increased injection there was a decrease in the agglutination, intravenous injections must be given. Among 75 patients treated in this way it was found that the blood serum of 65 produced agglutination when mixed with quantities of test-fluid varying from 25 to 300 times its weight and that there were only nine the serum from whom gave no result, the patients being all in an advanced stage of tuberculosis. He was of opinion that it was possible to produce in these cases a sufficient quantity of alexins by this method. That the agglutination was really an indication of the immunising action of the injections might be concluded from the fact that with the establishment of agglutination the general health and the objective symptoms of the patients showed an improvement. Fever was not a contra-indication as regards the injections, for in several cases the fever was found to disappear in the course of the treatment. Finally, Professor Koch recommended that the injections should be continued for at least six months, being given at considerable intervals till the tubercle had disappeared from the sputum.

#### *Deaths of Eminent Medical Men.*

Professor von Liebermeister, a very distinguished teacher of clinical medicine, died in Tübingen (Württemberg) on Nov. 24th. Born in 1833 he studied medicine at Greifswald University and after having become qualified was appointed an assistant to Professor Niemeyer, one of the most celebrated clinical teachers of that time, with whom he went to Tübingen, still in the capacity of his assistant, and subsequently became professor of medicine at the University of Basle in Switzerland. After the death of Professor Niemeyer Professor von Liebermeister succeeded him in the chair of clinical medicine at Tübingen which he held till his death. His principal work was on the theory of fever and the treatment of enteric fever. He was one of the first physicians who used the cold-water treatment in this disease. He was also the author of a book on diseases of the liver.—Dr. Löhlein, professor of obstetrics and gynaecology in the University of Giessen, died on Nov. 24th. He was born in 1847 and after having qualified at Berlin he became assistant to the late Professor Schröder, then chief surgeon to the university lying-in hospital. In 1888 he was appointed ordinary professor at Giessen. His published works treated of rachitic conditions of the pelvis, eclampsia, and osteomalacia. It was owing to him that systematic courses of instruction were made compulsory for registered midwives and that homes were established where women could stay after their confinement.

Dec. 9th.

## Obituary.

SURGEON-GENERAL ROBERT HARVEY, C.B., D.S.O.,  
M.D., LL.D. ABERD., F.R.C.P. LOND.,  
DIRECTOR-GENERAL OF THE INDIAN MEDICAL SERVICE.

In our last issue we recorded the sudden death at Simla of Surgeon-General Robert Harvey, Director-General of the Indian Medical Service, thus bringing to an unexpected end a varied, brilliant, and successful career, at a moment when his tenure of office was drawing to its close and he was ripe for further distinction and honour. Surgeon-General Harvey was among us in England only the other day, apparently in the best of health and spirits, and ready, able, and willing to bring his keen mind to bear on the important questions raised by the reorganisation scheme of the sister service as it affects the department of which he was the head.

Robert Harvey was born at Aberdeen on March 10th, 1842, being the eldest son of Alexander Harvey of Broomhill, Aberdeenshire, Regius Professor of Materia Medica in the University of Aberdeen. He received his general education under private tutors and began his medical studies at the early age of 16 years, taking out courses of lectures both at Aberdeen University and at Glasgow University; he finally took his degree with honours in 1863.

After graduating Robert Harvey's special abilities as a student secured him an appointment as resident accoucheur to the Birmingham General Dispensary and after holding this post for a year he entered the Army Medical Department, taking the second place among 72 competitors. A purely military career, however, did not offer sufficient attractions to a man of his temperament and versatility and in 1865 he entered the Indian Medical Service, landing in India at the end of that year. Immediately after his arrival he took part in the Bhutan campaign of 1865-66, earning a medal and clasp. From 1866 to 1871 he was residency surgeon to the Eastern Rajputana Agency, in which latter year he volunteered for the Lushai expedition, and on its conclusion he served with the Central India Horse for four years. At the expiration of this period he was appointed civil surgeon of Simla for two years (1876-77) and thus began that brilliant period of civil employment by which probably he will be chiefly remembered in India. In 1878 he was offered, and accepted, the post of Sanitary Commissioner for Lower Bengal, filling up spare time by rescuing from oblivion the valuable records of medico-legal work annually buried in the official returns of that province. In recognition of the value of this work he was in 1879 made a Fellow of the Calcutta University. On the retirement of Dr. Edmonstone Charles in 1880 Robert Harvey was appointed professor of midwifery in the Medical College of Calcutta and obstetric surgeon to the Eden Hospital, then almost completed, an institution which by his energy and devotion he succeeded in making the finest and most beautiful building of the kind in India. As a teacher he proved himself to be clear, forcible, and incisive, showing perfect mastery of the subject in which he had already distinguished himself. At this time he entered on a very successful career of private and consulting practice, for which his kindness, his tact, and his professional and general attainments rendered him eminently suited, and wealth and honours began now to be showered upon him. In 1882 he was made a Doctor of Laws of the University of Aberdeen, in 1883 honorary surgeon to the Viceroy, and in 1885 an Honorary Fellow of the British Gynaecological Society. In 1889 he obtained the Membership of the Royal College of Physicians of London by examination. For a short time, also, he officiated, in addition to his other duties, as Principal of the Calcutta Medical College.

By that rule which compels a member of the Indian Medical Service at a certain stage in his career, either to resign his commission and the civil duties for which he is perfectly fitted by ability and inclination, or to accept promotion to the administrative grades, Robert Harvey was obliged to give up civil employment and to return to military duty, and he was accordingly appointed principal medical officer at Peshawur in 1890, and from 1891 to 1893 he acted in the same capacity with the Punjab Frontier Force, during which time he took part in the Miranzai and in the Isazai expeditions, being mentioned in despatches and obtaining the Distinguished Service Order. At this period there occurred a severe and fatal epidemic of cholera at Srinagar in Kashmir, and Surgeon-General Harvey was sent to inquire into and to advise regarding it. For this service he received the thanks of the Governor-General of India in Council.

For a short time in 1893-94 Surgeon-General Harvey returned to civil employment as inspector-general of civil hospitals in Lower Bengal, when he was largely instrumental in bringing to a successful issue the project of an International Medical Congress. This congress was held in Calcutta in December, 1894, and he was appointed its president. At this time, also, the Fellowship of the Royal College of Physicians of London was conferred on him. In 1895 he returned to military employment in the capacity of principal medical officer to the Punjab command, receiving the Jubilee medal in 1897, and the Companionship of the Bath in 1898 for the success with which he conducted the medical arrangements for the Tirah campaign in which he took part.

In 1898 Surgeon-General Harvey rose to the highest appointment in the department to which he belonged and of which he had long been one of the most distinguished

officers—that of Director-General of the Indian Medical Service. During his incumbency of this post India was overwhelmed with famine and plague, and the anxiety and work which these combined calamities entailed on the man who was responsible for the efficiency of the medical arrangements not only for the teeming 300,000,000 of the people of India, but to prevent the conveyance of the pestilence from its ports, must have told severely on a constitution at no time robust and which had been weakened by severe illnesses. These labours doubtlessly contributed to the fatal result of that last illness of which intelligence has so recently arrived. Of Robert Harvey it may truly be said that he was ever lavish of his strength, whether the call upon it was made by his friend, by his patient, by his duty, by his department, or by the Government which he served, and that he was ever actuated only by the highest codes of personal and professional honour. He died at his post, honoured, decorated, and regretted.

Surgeon-General Harvey married Emmie Josephine Drayton, daughter of J. Drayton Grimke, of Ashley Grange and Charleston in the United States. He has left a widow, but no children. In accordance with his wish his body was cremated.

#### HENRY PIERS, M.R.C.S. ENG., L.S.A.,

DEPUTY INSPECTOR-GENERAL OF HOSPITALS AND FLEETS (RETIRED).

DEPUTY INSPECTOR-GENERAL PIERS died at his residence, Burnham, Somerset, on Nov. 30th, in his eighty-fourth year. He received his medical education at Guy's Hospital, taking the qualifications of M.R.C.S. Eng. and L.S.A. in 1840 and 1841 respectively. In 1846 he entered the medical department of the Royal Navy, and served first on the East Coast of Africa, and subsequently in the Arctic Expedition sent in search of Sir John Franklin and his party, and for the discovery of the North-west passage round America. Mr. Piers was on H.M.S. *Investigator* which sailed with H.M.S. *Enterprise* from Plymouth in January, 1850, he being rated as assistant surgeon and Mr. Alexander Armstrong being surgeon. The expedition, as it will be remembered, failed to find Sir John Franklin, but succeeded in discovering the North-west Passage. On his return Mr. Piers received the Arctic medal and afterwards was stationed on the Pacific Coast, chiefly at Vancouver's Island and for a short time in the West Indies. Later, as Deputy Inspector-General of Hospitals and Fleets, he held appointments in Ireland and at Chatham. On leaving the Royal Navy Mr. Piers settled in Burnham where he was highly respected. He was for many years the honorary secretary of the local branch of the Royal National Lifeboat Institution, to which he rendered valuable assistance. The deceased gentleman leaves a son, Major Piers, who is at present invalided home from Cashmere. The funeral took place on Dec. 5th at Barrow Churchyard, near Burnham, amid many tokens of sympathy.

#### JOHN DAVIES HARRIES, M.R.C.S. ENG., L.S.A.

THROUGH the death of Mr. J. D. Harries from pneumonia on Nov. 29th the medical profession in Shropshire loses one of its oldest and most respected members. Though born in Shrewsbury in the year 1835 Mr. Harries came of an old Pembrokeshire family. After serving an apprenticeship with Mr. Henry Keate of Shrewsbury he entered as a student of King's College and became M.R.C.S. Eng. in 1857 and L.S.A. in the year following. In 1860 he was appointed surgeon to the Salop County Gaol, a position which he held at the time of his death. He was also surgeon to the Shrewsbury Penitentiary, honorary surgeon-extraordinary to the Salop Infirmary, and he took an active interest in the British Medical Association as the representative upon the central council of the Shropshire and Mid-Wales branch. Mr. Davies was on the commission of the peace for the borough of Shrewsbury, a trustee of the borough charities, in the administration of which he was particularly interested, and for 25 years, until 1890, he was a member of the Shrewsbury Corporation.

THE Middlemore Post-Graduate Lecture, an annual lecture under the Middlemore Trust, will be delivered at the Eye Hospital, Birmingham, on Thursday, Dec. 19th, at 4.30 P.M., by Mr. H. Eales, senior honorary surgeon to the institution, who has chosen for his subject, "Some Functional Disorders of Vision."

## Medical News.

UNIVERSITY OF CAMBRIDGE.—At the congregation held on Dec. 5th the following medical degrees were conferred:—

*Doctor of Medicine*.—J. Cropper, Trinity; H. W. P. Young, Gonville and Caius; and S. E. Denyer, C.M.G., Queen's.

*Bachelor of Medicine*.—A. T. Fraser, Gonville and Caius.

*Bachelor of Medicine and Bachelor of Surgery*.—F. K. Weaver, Trinity; T. Gillespie, St. John's; and A. C. Ingram, St. John's.

Mr. Edmund Owen and Mr. Mansell Moullin have been appointed Examiners in Surgery and Dr. D. Hood Examiner in Medicine for the current Third M.B. Examination. Mr. H. B. Roderick, Emmanuel, has been appointed Demonstrator of Surgery under Dr. J. Griffiths.

FREEMASONRY.—*Rahere Lodge, No. 2546*.—An ordinary meeting of this lodge was held at the Frascati Restaurant on Dec. 10th. W. Bro. P. S. Abraham, W.M., being in the chair. Mr. Walton R. Read was initiated into Freemasonry. W. Bro. J. Peplow Cartwright, P.G.R. Shropshire, was elected a joining member. Bro. Edge was admitted to the second degree and Bro. Keown to the third degree. The Worshipful Masters of the Middlesex Hospital Lodge, the Chère Reine Lodge, the London Hospital Lodge, and the Cheselden Lodge were elected honorary members of the Rahere Lodge during their year of office. The jewel of a S.G.C. was voted by the lodge to W. Bro. the Rev. Sir Borradaile Savory, Bart., and of a Deputy G. D. C. to W. Bro. Gripper, I.P.M., on the occasion of their appointment to Grand Office by H.R.H. the M.W. Grand Master. A sum of 10 guineas was contributed out of the lodge funds to each of the three Masonic charities. The brethren and their guests afterwards dined together.

#### BRITISH MEDICAL TEMPERANCE ASSOCIATION.

A meeting for medical students was held on Dec. 5th, in the Governors' Hall of St. Thomas's Hospital (by kind permission of the Treasurer). Dr. H. G. Turney, dean of the medical school, presided. In opening the conference he said that he thought the medical profession rather lagged behind public opinion on the subject of temperance. Abroad the reverse was the case. The alcoholic habit was an endemic disease here and was responsible for an amount of disease and death which it was difficult to appreciate. The death certificates in this country did not adequately indicate its extent, but in Switzerland a system of State certification had revealed that during the last 15 years one in 10 males and one in 50 females died from some disease connected with alcohol. In Prussia alone in 1895 over 10,000 people were being treated for the alcoholic habit. This was a problem which it was the special duty of the medical profession to work out. Among those who took part in the discussion which followed were Dr. J. J. Ridge, Dr. C. R. Drysdale, Mr. F. Churchill, and some of the students.

HARVEIAN SOCIETY OF LONDON.—The annual dinner of this society was held on Nov. 28th in the Regent Saloon of the Café Monico. The chair was occupied by Dr. David B. Lees, the President, and 77 members and guests sat down to dinner. Amongst those present were Sir Thomas Barlow, Sir G. Anderson Critchett, Mr. H. G. Howse, Dr. W. H. Allchin, Mr. Howard Marsh, Mr. Alfred Cooper, Mr. Watson Cheyne, Dr. J. Dundas Grant, Mr. G. P. Field, Mr. Edmund Owen, Mr. Noble Smith, and Mr. C. R. B. Keetley. The usual loyal toasts having been proposed by the President, Dr. Allchin, President of the Medical Society, proposed "Success to the Harveian Society," briefly sketching the career of the society from its foundation in 1831 and pointing out the various causes which rendered it such an attractive society.—Dr. Lees responded for the society.—Mr. Keetley then proposed "The Sister Societies" and "Our Guests," drawing a fancy picture of what the profession might become in a few years' time should the members adopt trade union principles in their work.—Mr. Howard Marsh, President of the Clinical Society, responded for the sister societies and Mr. Howse responded for the guests.—"The President" was proposed by Mr. Noble Smith, Dr. Lees replying, and in his speech proposing "The Honorary Secretaries," to which toast the senior secretary (Mr. Hubert C. Phillips) replied.—In the intervals between the

speeches a selection of excellent music under the able direction of Mr. Herbert Schartau was rendered. The artists were Master Harold Davis, Mr. William Fell, Mr. George Stubbs, and Mr. Valentine Hill.

On Dec. 6th, at the Victoria Hall, Weston-super-Mare, Dr. H. A. Ballance delivered an interesting lecture, entitled, "Experience in South Africa while with the Imperial Yeomanry." The rector (the Rev. Prebendary de Salis) presided and the proceeds are to be devoted to the building fund of the proposed sanatorium at Winsley.

**DIPHTHERIA IN GLAMORGANSHIRE.**—At the meeting of the Sanitary Committee of the Glamorgan County Council held on Dec. 6th Dr. W. Williams, medical officer of health of the county, reported that at Cwmavon 100 cases of diphtheria had been notified from January to September, with nine deaths, and that at Aberkenfig 38 cases of diphtheria had occurred, of which 13 (or 33 per cent.) had proved fatal.

**DURHAM UNIVERSITY MEDICAL GRADUATES' ASSOCIATION.**—Under the auspices of the Southern Division of the association the autumnal dinner was held at the Café Monico on Dec. 5th. Dr. Frederick S. Palmer, the president of the association, was in the chair and about 60 members and guests were present. Music was provided by Mr. F. Peachey, Mr. Aspinall, and Mr. F. Ross, and formed a pleasant feature in a successful evening's entertainment.

**VACCINATION PROSECUTIONS.**—At Abertillery Police-court on Dec. 6th two parents were summoned to show cause why they had not paid fines, amounting to £2 10s., respectively, imposed in March last, for failing to comply with the Vaccination Act. The local anti-vaccination society defended, and a plea of "conscientious inability" was raised. The magistrates ordered distress warrants to be issued, to be suspended for a month, or in default seven days' imprisonment as first-class misdemeanants.

**THE LATE DR. W. ROBERTSON.**—The inhabitants of Glanton and district (Northumberland) have erected, by public subscription, a handsome memorial stone in Bolton churchyard to the memory of the late Dr. W. Robertson of Glanton. Dr. Robertson, who died in May last at the ripe age of 80 years, practised for 54 years in the district. He took a great interest in the public affairs of the neighbourhood and was honoured and esteemed professionally and socially by all who knew him. His decease is much regretted.

**WORKMEN'S COMPENSATION ACT.**—At the Cardiff County-court on Dec. 6th a somewhat singular action was brought under the Workmen's Compensation Act. The plaintiff was a woman whose husband is at present in a lunatic asylum and the defendants were the Mountstuart Dry Dock Company. The man was injured in June last whilst at work on a ship in Roath Dock, but there was no evidence as to the actual accident as he was found unconscious in the hold. Whilst under treatment at the Cardiff Infirmary insanity supervened, probably caused by the accident, and it became necessary to remove him to a lunatic asylum. An order was made by consent for £1 per week during incapacity.

**IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.**—The autumn general meeting of the above association was held on Nov. 27th at the Hotel Cecil, London, Dr. William Alexander of Liverpool, the President, being in the chair. There was a large attendance of members. The council reported that Mr. P. J. Freyer, who had held for four years the post of metropolitan honorary secretary, had been appointed chairman of council in succession to Dr. T. Gilbert Smith whose period of office had expired. Mr. Stewart proposed, and Dr. W. H. Bourke seconded, and it was carried by acclamation, that the heartiest thanks of the association should be accorded to Dr. Gilbert Smith for his valuable services at the head of the executive during the last three years. The meeting then adjourned. The members and their guests to the number of 102 sat down subsequently to dinner in the Victoria Hall. The guests of the evening were Sir Charles Crosthwaite, K.C.S.I., late Lieutenant-Governor of the North-west Provinces of India, and his Honour Dr. J. A. Rentoul, K.C., M.P. The toasts were commendably few. The proposers and those who responded included the guests

of the association, the Hon. H. B. Lefroy (Agent-General for West Australia), Mr. Atherley Jones, K.C., M.P., Inspector-General Lloyd, Mr. C. B. Ball, Inspector-General Turnbull, and Surgeon-Captain R. R. Sleman (senior medical officer, C.I.V.). Songs, recitations, and humorous sketches were given by Miss Jessica Leeson, Miss Elsie Southgate, Mr. J. L. Shine, and Mr. Arthur Helmore. Mr. Dunn and Mr. Norfolk Megone accompanied.

MR. G. MELLIN has placed at the disposal of the Prince of Wales's Hospital Fund for London a quantity of Mellin's Food equivalent in value to £10,000 to be distributed among London hospitals at the rate of £2500 worth per annum.

**CARDIFF INFIRMARY.**—Two amateur dramatic performances are to be given at the Theatre Royal, Cardiff, on Dec. 18th and 19th, by gentlemen connected with the various insurance companies of the town, the proceeds of which are to be devoted to the maintenance of an "insurance cot" in the Cardiff Infirmary. Last year, when the scheme was initiated, the sum of £125 was raised for the purpose.

**THE ROYAL NATIONAL PENSION FUND FOR NURSES.**—The authorities of the above fund have issued a souvenir of the recent reception by Her Majesty Queen Alexandra of the Pension Fund nurses at Marlborough House which took place in July last. The fund owed its inception to Sir Henry Burdett and to the generosity of Mr. Junius Morgan, Mr. E. A. Hambro, Lord Rothschild, and Messrs. Anthony Gibbs and Sons, and was incorporated in 1888. Over 9000 nurses have joined it and the souvenir before us will be a pleasant reminder to the members of the Fund of the interest taken in their career by the highest in the land.

**PREVENTION OF TUBERCULOSIS.**—A meeting was held in Plymouth on Dec. 3rd, under the auspices of the Devon and Cornwall Branch of the Association for the Prevention of Consumption and other Forms of Tuberculosis, to consider the desirability of establishing a sanatorium for the open-air treatment of the consumptive poor of Devon and Cornwall. The Mayor of Plymouth presided, and amongst others present were the Earl of Mount Edgcumbe, Mr. J. W. Spear, M.P., Dr. H. Davy (Exeter), Dr. R. H. Clay, Dr. E. Fox, Dr. W. Webber, and Dr. F. G. Bushnell. On the proposition of the Earl of Mount Edgcumbe it was unanimously resolved that it was desirable to establish a sanatorium in the neighbourhood of Plymouth and a representative committee of the two counties was appointed. It was mentioned that an eligible site on Dartmoor had been offered.

**THE ST. JOHN AMBULANCE BRIGADE.**—The Osborn challenge shield, which was competed for on Oct. 26th, in the grounds of the Charterhouse, was first offered for competition in 1900 by Mr. S. Osborn, the chief surgeon of the metropolitan corps. The conditions of the competition are that each division of the metropolitan corps may send a team of four men, accompanied by four other members of the division to act as patients, and that each member of the team shall treat an individual injury and the team collectively a case. Improvised appliances only are used. The following were the competing teams in order of merit: (1) South Metropolitan Gas Company; (2) East Ham; (3) East London; (4) Causton; (5) Merton and Wembley. Recently the honorary surgeons of the metropolitan corps of the brigade gave a complimentary dinner to their chief surgeon, Mr. S. Osborn. Mr. J. Brown presided. Mr. J. Cantlie, in proposing the health of the guest, remarked that the constitution of the service was exactly parallel to the old organisation of the Army Medical Corps. That system had much in it that was admirable. The fact that the surgeon was free to devote his attention to professional work in the corps and to leave the organisation, equipment of transport, and the transport itself to other workers had much to recommend it, but it required great tact and judgment to attach medical men to the brigade and yet to give them no power or voice in the command or direction of their corps. Medical men were easily dealt with when it was a question of giving their services, and so long as the surgeons of the brigade through the tact and discretion of the chief surgeon were considered and treated by the authorities with the courtesy which they believed to be their due so long would the present régime continue and there would be no necessity for taking the step which their brethren in the army were compelled to take;

and what was necessary for military might become by injudicious management at any moment necessary for civil ambulance organisation. He sincerely trusted that Mr. Osborn might long hold his present position of chief surgeon to the metropolitan corps. Mr. Osborn in his reply, after referring to the organisation of the corps, said that in the matter of work with improvised material there was still much to be desired. It was for this work that he had given a challenge shield in the hope of improvement and getting the men to show their ingenuity. They relied too much upon their book and muddled up the information they got out of it. At the close of the dinner it was decided that there should be an annual dinner of the honorary surgeons of the metropolitan corps.

**AN INTERESTING PRESENTATION.**—On Dec. 9th the board-room of the General Hospital, Birmingham, was the scene of a worthy tribute to one of the best friends the hospital has had since the time of the original founder, Dr. Ash. The chair was taken by Lord Howe, who, on behalf of some 208 subscribers, presented to Sir John Holder a portrait of himself, painted by the Hon. John Collier, and a replica of the same to Lady Holder. A silver casket, containing an illuminated address with the names of the subscribers, accompanied the presentation. The address expressed recognition of Sir John Holder's personal devotion to the best interests of the hospital in addition to the financial support so unceasingly and liberally given during the years occupied in the planning, building, and fitting up of the institution. Sir John Holder acknowledged in feeling terms the pleasure with which he received the presentation, and stated his high appreciation of the help that his colleagues on the board of management had always given to him during the past 11 years. Eleven years ago the idea of building a new hospital was originated by a gift of £25,000 from Miss Ryland; the scheme grew beyond expectation and has culminated in the beautiful and appropriate hospital as it now stands.

#### Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

- ARMSTRONG, W. B., M.B., C.M. Glasg.,** has been appointed Certifying Surgeon under the Factory Acts for the Kirkintilloch District.
- BARFORD, A. M., M.D., L.R.C.P., M.R.C.S.,** has been appointed Anaesthetist to the Throat Hospital, Golden-square.
- BENNETT, WILLIAM B., M.R.C.S. Eng., L.R.C.P. Lond.,** has been appointed Honorary Surgeon to the St. George's Hospital for Diseases of the Skin, Liverpool.
- BERSFORD, EDWIN H., M.R.C.S., L.R.C.S. Lond.,** has been appointed Medical Superintendent of the New Metropolitan Asylum, Tooting Bec.
- BEVAN, ARTHUR, M.B. Lond.,** has been appointed House Physician to the Hospital for Sick Children, Great Ormond-street.
- CLAYTON, JOHN CECIL, L.R.C.P. Lond., M.R.C.S. Eng.,** has been appointed House Surgeon to the Bristol Eye Infirmary.
- COLLINS, E. TREACHER, F.R.C.S.,** has been appointed Visiting Ophthalmic Surgeon to the Metropolitan Asylums Board Ophthalmia Isolation Schools at Brentwood and Swanley.
- CUNNINGHAM, JOHN, M.B., C.M. Glasg.,** has been appointed Certifying Surgeon under the Factory Acts for the Stewarston District of Ayrshire.
- CUTHBERTSON, J. O., M.B., B.Ch. Oxon.,** has been appointed Senior House Surgeon, Radcliffe Infirmary, Oxford.
- DALY, JOSEPH P., M.D., M.Ch. R.U.I.,** has been appointed Certifying Surgeon under the Factory Acts for the Monasterevan District of the county of Kildare.
- DARLEY, A. R., M.D. Dub.,** has been appointed Medical Officer of Health for Daventry.
- GUNN, C. B., M.D. Edin.,** has been appointed Certifying Surgeon under the Factory Acts for the Peebles District.
- HARDENBERG, E. J. F., M.R.C.S. Eng., L.R.C.P. Lond.,** has been appointed Junior Resident Medical Officer to the North-west London Hospital.
- HUNTER, WILLIAM, M.B., C.M. Aberd.,** has been appointed Government Bacteriologist to the colony of Hong-Kong.
- MCGAVIN, LAWRIE, F.R.C.S.,** has been appointed Clinical Assistant in the Throat Department of Guy's Hospital.
- MEACHEN, G. NORMAN, M.B., B.S. Lond., M.R.C.P. Edin.,** has been appointed Honorary Physician to the St. Pancras and Northern Dispensary.
- MUSCHAMPE, R., L.R.C.P. Edin., L.R.C.S. Edin.,** has been appointed Medical Officer of Health for the Yeading Urban District Council.
- NYHAN, DENIS, L.R.C.P. Edin., L.R.C.S. Edin.,** has been appointed Certifying Surgeon under the Factory Acts for the Brynmawr District of Brecknockshire.
- PAKES, WALTER C. C., D.P.H. Cantab., F.C.S.,** has been appointed Analyst and Bacteriologist to the Transvaal Government.
- PERCIVAL, F., M.R.C.S., L.R.C.P. Lond.,** has been appointed Medical Superintendent of Prestwich Asylum.
- PERBOTT, CHARLES JOHN, L.R.C.P., L.R.C.S. Irel.,** has been re-appointed Medical Officer of Health for the Kingswood Urban District Council.

PRITCHETT, G. W. MORRIS, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Senior Resident Medical Officer to the North-west London Hospital.  
 SMARTT, WALTER, F.R.C.S., L.R.C.P. Irel., L.M., has been appointed Medical Officer and Public Vaccinator to the Tarporley District of the Tarvin Union.  
 WALLACE, STANLEY, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Medical Officer of Health of the Town of Skegness, Lincs.

## Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

**BIRMINGHAM GENERAL DISPENSARY.**—Resident Surgeon, unmarried. Salary £150 per annum, with rooms, fire, lights, and attendance.  
**CHELSEA, BROMPTON, AND BELGRAVE DISPENSARY, 41, Sloane-square, Chelsea, S.W.**—Honorary Surgeon.  
**DEVONSHIRE HOSPITAL, Buxton, Derbyshire.**—House Surgeon and Assistant House Surgeon. Salary, House Surgeon £100 per annum, Assistant £50 per annum, with apartments, board, and lodging.  
**EYE AND EAR INFIRMARY, Liverpool.**—House Surgeon. Salary £80, with residence and maintenance.  
**GLASGOW ROYAL INFIRMARY.**—Superintendent. Salary £500 per annum, with board, residence, &c.  
**GREAT NORTHERN CENTRAL HOSPITAL.**—Assistant House Surgeon for six months. Salary at the rate of £30 per annum, and board.  
**HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.**—Resident House Physicians for six months. Honorarium of £25.

The Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies under the Factory Acts as Certifying Surgeons at Tarporley, in the county of Cheshire; at Wick, in the county of Caithness; at Whitechurch, in the county of Hants; and at Earl Shilton, in the county of Leicester.

## Births, Marriages, and Deaths.

### BIRTHS.

**COLEMAN.**—On Dec. 3rd, at Beaufort House, Castle-street, Reading, the wife of Maurice W. Coleman, M.B. Lond., of a son.  
**SAVERY.**—On Dec. 2nd, at 4, Mount Park-road, Ealing, the wife of Frank Savery, M.R.C.S., L.R.C.P., of a daughter.  
**WILSON.**—On Dec. 3rd, at Elstree Cottage, Bushey Heath, Herts, the wife of Daniel Wilson, M.A., M.D. Queen's Coll., Cork, of a son.

### DEATH.

**HARVEY.**—On Dec. 1st, at Simla, Surgeon-General Robert Harvey, C.B., D.S.O., F.R.C.P., LL.D., Director-General of the Indian Medical Service, eldest son of the late Dr. Alexander Harvey, Regius Professor of Materia Medica in the University of Aberdeen.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## Notes, Short Comments, and Answers to Correspondents.

### PURE UREA IN THE TREATMENT OF TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—Dr. H. Harper's papers on the treatment of tuberculosis by the administration of urea (see THE LANCET of March 9th, p. 694, June 15th, p. 1672, and Dec. 7th, 1901, p. 1567) are particularly interesting, and more especially so from the fact that I believe a M.D. was about 30 years ago struck off the roll of the College of Physicians for recommending boia constrictor's urine (which is especially rich in urea) in cases of the same character. I cannot say that I believe much in the hereditary transmission of phthisis or in the milk-conveyance theory, since the inhalation of the dried tubercle-laden sputum accounts better than anything else both for the disease attacking one after another of the same family and also for the appearance of isolated cases. In the treatment of phthisis there is no question that what we have to do is to improve as much as possible the vital powers of the patient and to render him more capable of resisting the action of the bacillus. The use of urea should certainly have a wide and extended trial.

I am, Sirs, yours faithfully,

Bexhill-on-Sea, Dec. 9th, 1901.

F. P. ATKINSON.

### A NEW RENDERING.

WE extract the following reply to a correspondent from the *Echo* of Dec. 9th:—

(16) DOMESTIC MEDICINE BOOK.—I saw advertised in the *Chronicle* a book upon domestic medicine by Cassell and Co. I have pleasure in stating this in reply to "Family Man." I also suggest that "a man who is his own lawyer has a fool for his client," and that if for "lawyer" the word "doctor," and if for "client" the word "patient" be substituted, the proverb is equally correct, perhaps more so.

Quite so. And as we have often found fault with the replies to medical questions in lay journals it is only fair that when we totally agree with an answer we should publicly record the fact.

### "LOOKING BACK."

To the Editors of THE LANCET.

SIRS,—With reference to Jonah's residence in the whale's belly (see THE LANCET, Nov. 30th, p. 1519) the theory that he was very much alive during his sojourn in his host would be unhesitatingly affirmed by the unknown author of the "Prayer of Jonah while in the Belly of the Whale." This "prayer" used to be recited with great gusto by my old schoolmaster who learnt it when a lad in Scotland. I can only recall the first verse:—

"O Lord, how dismal is this place!  
 I've neither coal nor candle,  
 And nought I see but fish's tripe  
 And greasy guts do handle."

I am, Sirs, yours faithfully,

Harley-street, W., Dec. 4th, 1901.

WILLIAM RUSHTON.

### FRIENDLY SOCIETIES AND THEIR MEDICAL AID INSTITUTIONS.

To the Editors of THE LANCET.

SIRS,—My letter to you on the above subject in THE LANCET of Nov. 30th, p. 1554, was simply to demonstrate "the legal position" of an institution of this character as contrasted with "an insurance and medical aid friendly society" where canvassing, &c., is permitted. Mr. J. B. Pike characterises my letter as insolent. I have submitted it to several medical gentlemen who agree that it is courteous in its tenor and a marked contrast to the malignant spirit with which it has been answered. I happened to be on the committee deputed to meet the members of the General Medical Council. Before and after fully explaining our position we were treated with the greatest courtesy and kindness—just what we expected from members of the noblest and greatest of professions. I confess we are not faultless and in many instances medical men are inadequately rewarded for their services, but the spirit in which Mr. Pike discusses the subject will never tend to conciliate the clubs and their surgeons. Mr. Pike flies off at a tangent: he says that the institutions are not self-supporting, for in case of accident or severe operation they fall back on the hospital and its surgeons. To this I say emphatically they are self-supporting, and the reason why they seek the hospital aid occasionally is because they contribute largely in the aggregate towards its existence. Every employé at factories and warehouses in all our big provincial towns is compelled to contribute a small sum weekly. In Bradford, Leeds, Hull, Manchester, &c., no mean sum is contributed. In all the colliery districts the same rule exists. The employés are the thrifty workmen and workwomen who form 95 per cent. of the members of a friendly society's medical institution!

I am, Sirs, yours faithfully,

Dec. 9th, 1901.

C. W.

## FEES FOR INSURANCE EXAMINATIONS.

To the Editors of THE LANCET.

SIRS.—My experience with the Century Insurance Company, Edinburgh, may act as a warning to others. The company advertises itself as being specially suitable to the requirements of medical men. I was asked to examine a candidate for sickness insurance. The examination required was unusually rigorous, including physical examination, testing urine, chest measurements, &c. The report consisted of three sides of foolscap and about 60 questions had to be answered. A fee of 10s. 6d. was sent to me, and though I have protested I have been unable to get my usual fee of one guinea for insurance examinations.

I am, Sirs, yours faithfully,

Nov. 12th, 1901.

CYCLOPS.

## THE PREPARATION OF HUMANISED MILK.

To the Editors of THE LANCET.

SIRS.—Can any of your readers kindly tell me the different methods of preparing humanised milk and the different ways of sterilising milk, as well as refer me to reliable literature where these prepared milks are contrasted with raw cow's milk in the feeding of children?

I am, Sirs, yours faithfully,

Dec. 3rd, 1901.

GLASGOW.

## AN ADVERTISING PRACTITIONER.

IN THE LANCET of Jan. 19th, 1901, p. 224, we compared the wording of the circular which we print below with the methods of a certain quack so-called medical alliance. On that occasion we withheld the medical man's name, but stated that we should give him full publicity if his methods remained unaltered. We have now received another complaint from a correspondent who occasionally finds the circular in his letter-box.

"Consultation, with or without medicine, One Shilling;  
Medicine 6d.

Examination, with or without certificate, Half-a-crown for Clubs,  
Insurances or other Societies.

At home Nine to Eleven o'clock every morning, at Three  
o'clock every Afternoon; and Seven to Eight  
o'clock every evening.

Sundays after 6 o'clock. Forenoon by Appointment.  
Medicine and Attendance, Half-a-crown each week or part of a  
week.

No further charge for the remainder of the week. Seven days to  
the week, commencing at any time.

Vaccination, One Shilling; from Calf Lymph, Half-a-crown.

Teeth Extracted One Shilling each; Painless,  
Half-a-crown.

Teeth Stopped Half-a-crown each; and Artificial Teeth, One  
Guinea the Set.

Visiting Payments after Ten o'clock at Night, and before  
Eight o'clock in the Morning, according to time  
and distance.

Attendance includes Visits when patients are not able to attend at  
the Doctor's Surgery.

Midwifery, Accouchements, Confinements, Half-a-guinea, Fifteen  
Shillings, One Guinea and Two Guineas, according to agreement  
beforehand, when half the fee may be paid. The fee includes One  
week's after attendance and medicine.

Drugs, Medicines and Proprietary Articles at Cash Prices.

Diseases of Women and Children attended.

Apply—

DR. SARGENT,

Physician, Apothecary, Accoucheur, and Surgeon,

7, STATION ROAD, BRIXTON,  
LONDON, S.W.

Teeth Extracted at any hour guaranteed painless.

The above are only for Cash payments, paid in advance."

## A SUGGESTION FOR TREATMENT.

To the Editors of THE LANCET.

SIRS.—I have seen a similar case of bronchial asthma that is described by your correspondent, "M.B. Lond.," in THE LANCET of Nov. 30th, p. 1554, practically cured by giving the "glycérophosphate de soude," Robin, by subcutaneous injection—one dose per diem for a week or two. The preparation is to be obtained in London from Mr. Jozeau, chemist, 49, Haymarket, S.W.

I am, Sirs, yours faithfully,

Dec. 9th, 1901.

W. HARLE.

To the Editors of THE LANCET.

SIRS.—"M.B. Lond." in THE LANCET of Nov. 30th, p. 1554, might find one drachm of paraldehyde useful, with a second dose in about an hour of from 30 to 45 minims if necessary.

I am, Sirs, yours faithfully,

FREDERIC P. HEARDER.

West Riding Asylum, Wakefield, Dec. 10th, 1901.

## HÆMATURIA AFTER EATING LAYER.

To the Editors of THE LANCET.

SIRS.—Would any of your readers—Irish especially—kindly say if in their experience the eating of laver, or slöke, has been followed by hæmaturia? as an aged patient here has heard that this is so, particularly if it be eaten before frost. He had partaken of it for some days (as he had often done with impunity) and intense hæmaturia suddenly occurred with no local or general symptom and most obscure etiology.

I am, Sirs, yours faithfully,

Winchester, Dec. 10th, 1901.

W. M. HARMAN.

## THE CASE OF THE LATE MR. W. K. BROCK.

To the Editors of THE LANCET.

SIRS.—May I ask you very kindly to acknowledge the following sums received in answer to the appeal for the family of the late Mr. W. K. Brock:—Mr. Snook (Weymouth), £1; Anon. (Northampton), 10s.

I am, Sirs, yours faithfully,

Dec. 9th, 1901.

JONES, Hon. Sec.

## UNCLEANLY MILK.

MR. W. HOGGEN, of Child's Hill, writes to us to point out that, while dairy inspectors are very particular as to the condition of the dairies and the cowsheds, making every inquiry into the drainage, air capacity, and flooring of the latter, they do not take into consideration the state of the cow. He points out that, in his personal experience, too many cows are kept in a dirty condition so that in the act of milking a certain amount of dust and filth from their hides must fall into the pails. This, of course, is a condition of things that could easily be remedied by grooming the cow. Mr. Hoggen says that the life of the milking cow is much prolonged by steady attention to its personal cleanliness.

F.R.C.S.—King Edward's Hospital is a hospital for sick and wounded officers and its name was given by His Majesty's personal order. The hospital has been open for nearly two years, and upwards of 200 officers have received assistance there. It is situated in Grosvenor-crescent, and the patients, who are officers not well off, have their expenses paid by the ladies whose house it is. Amongst the medical men who have given their services gratuitously to the institution are Sir T. Smith, Sir R. Douglas Powell, Sir F. Treves, Sir W. Bennett, Mr. A. A. Bowlby, Mr. A. D. Fripp, Mr. G. H. Makins, Mr. Cheate, and others.

Enquirer.—The medical profession takes no general view upon the questions, while the correspondence that might be opened by the publication of "Enquirer's" letter is too voluminous to contemplate. The British Medical Temperance Association, the Church of England Temperance Society, and other temperance bodies will supply pamphlets, &c., upon application, giving various views upon the points. In 1888 the late Dr. George Harley communicated several papers to our columns upon "Moderate Drinking," which contain particulars that might be of interest to "Enquirer."

M.A., M.B., M.R.C.P.—The persons concerned in exploiting the so-called "cure" are, of course, quacks. No fear of outraging professional opinion will deter them from their practices of deluding the sick. It is so unlikely that any readers of THE LANCET will become their victims that we do not think it worth while to give space to exposing them. Possibly an amended Medical Act will enable the policeman to play a part in dealing with such persons.

Jeckry.—The Medical Defence Union might take up the case for one of its members. The General Medical Council cannot, of course, act upon private information; they must have evidence brought before them in a formal way and properly supported before they can prevent such abuses. The conduct described, if not actually "infamous in a professional respect," would certainly not be approved by the General Medical Council.

Scotie.—We do not consider such matters "all rot," as everything that tends to promote harmony among the medical men in a locality is of importance to the whole medical profession. B's wife need not be bound in the least, unless she or her husband so wishes, by B's professional relations with A.

A. N.—Medical opinion does not endorse to any extent the views of the author. Yet it is right that these views should be published, as all intelligent endeavours to solve a problem of the first importance to the human race ought, in our opinion, to be made known.

X. Y. Z.—Such circulars are very usually sent out. Care must be taken to send them only to persons whose names are actually upon the books of the vendor.

Fair Play.—The question is a purely legal one. In purchasing a practice conditions are usually imposed to prevent the situation described by our correspondent.

Bacchus.—The appointment is legal. It cannot matter whether the selected man applied for the post or was himself applied to.

B. T. U.—We do not consider in all the circumstances that the proposed fee of £2 2s. is too high.

A. O. should consult her medical adviser. We do not prescribe or suggest treatment.

Subscriber can describe himself as "L.R.C.P., L.R.C.S. Edin., Dentist."

Luz.—The information could be obtained at the British Museum.

J. G. P.—(1) No; (2) no; (3) yes; (4) no.

R. G.—Yes.

## METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

**THE HOSPITAL FOR SICK CHILDREN** (Gt. Ormond-street, W.C.).—4 P.M. Dr. Poynton: Cretinism and Allied Conditions.

**FRIDAY (20th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Dr. N. MacLehose: Clinique. (Eye.)

## EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

## MANAGER'S NOTICES.

## TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newspapers (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.	TO THE COLONIES AND ABROAD.
One Year ... .. £1 12 6	One Year ... .. £1 14 8
Six Months ... .. 0 18 3	Six Months ... .. 0 17 4
Three Months ... .. 0 8 2	Three Months ... .. 0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

During the week marked copies of the following newspapers have been received:—

Manchester City News, Southend Standard, Sunday Times, Public Health Engineer, Reading Mercury, Liverpool Mercury, Coleraine Herald, Macclesfield Times, Macclesfield Courier, Westmorland Gazette, Daily Despatch (Manchester), Kendal Mercury and Times, Dundee Advertiser, Bradford Observer, Yorkshire Post, Alliance News (Manchester), Vegetarian, Glasgow Herald, Manchester Guardian, Times of India, Pioneer Mail, Herald of Wales, Citizen, Spalding Press, Surrey Comet, Evesham Standard, Hertfordshire Mercury, Mining Journal, City Press, Local Government Chronicle Daily Express, Sanitary Record, Plumber and Decorator, Brighton Times, Railway Herald, Western Advertiser (Yeovil), Hastings and St. Leonards News, Surrey Advertiser, Local Government Journal, The Welshman, Middlesbrough Daily Gazette, Sussex Courier Derby Express, &c.

Subscriptions (which may commence at any time) are payable in advance.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

## THE PRACTICE OF MEDICINE AND ORIGINAL RESEARCH.

*Delivered before the West Kent Medico-Chirurgical Society on Dec. 6th, 1901,*

By JAMES F. GOODHART, M.D., LL.D. ABERD.,  
F.R.C.P. LOND.,  
CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

GENTLEMEN,—The years since 1834, when he first qualified whose long and honourable career this annual address is intended to commemorate and emphasise, are crowded with events in the progress of medicine. But it is not that thought that will be the burden of my theme to-night; it is rather this, how happy must he be, how rich must he feel, to whom it is given to be able to look back upon the wealth of experience that 67 years at least in the practice of medicine must have brought. And the one pity in it that I can see at the present moment is that Prior Purvis cannot deliver his own oration and unload himself for our benefit of his stores of knowledge. Would, indeed, that it were possible. How gladly should we listen to the richness of his knowledge.

"But how shall letters and paper  
Imprison the breadth of Life?"

\* \* \* \* \*  
Nay, how should a volume hold it,  
Inscribed with a human pen?"

And as this cannot be—for experience is largely incorporated with oneself and cannot be imparted—we must imagine what the story of his life would tell; and one thing we may be sure that would be revealed, would be the truth of the thought, that the practice of medicine all along is an original research. It is on that account that I have chosen it as the subject of my address, and I am the more impressed with its appropriateness because it was but the other day that the President of the British Medical Association, no doubt with that modesty that so much becomes a great position, delivered practical medicine bound hand and foot and cast it into the chamber of death. "Pondering," he says, "over medicine as it stands to-day the main fact that strikes me is how much more it owes to the biologists and the men of pure science than to the so-called practical men. The practical man is indispensable, but he is not, like the great biologists, a high priest of the Arcana of Nature." I to-night, in a position of greater freedom and less responsibility, am inclined to see in indispensability no more than the privilege I share in common with, say, the undertaker. But for the man of medicine I will certainly claim no less than that he is on an equality with the great biologists; and that all of us may be, all of us ought to be, some are, let us hope, these high priests of the Arcana of Nature. I shall therefore contend to-night that we all may be, in our daily round of seeing and treating patients, in observing and combating disease, as truly scientific workers in advancing the progress of knowledge as those who are called the prosecutors of original research. "Scientific work" at the present day seems to me to be understood to apply only to research divorced altogether from the practice of medicine and carried on in the laboratory of the chemist and the physiologist. Now, while yielding to none in my desire to see "pure science," as it is called, and as I have defined it, better paid and therefore more generally practised than it is at present, I am not prepared to admit by silence that the man who spends laborious days and nights in his laboratory is the only really scientific worker or the only man who in the future is to be of any real use in the development of medical knowledge. On the contrary, I am prepared to maintain something nearly the very opposite of that—viz., that the practitioner is the man who very often plans the coach, and that the function of the worker in the laboratory is to drive in the bolts and to put on the varnish. In other words, those engaged in the practice of medicine have often been, possibly have always been, and certainly in the future may again be, the

No. 4086.

pioneers who by their observations suggest the lines that the workers in the laboratory take up and follow to their conclusion. They may not drive the nail home to an epoch-making discovery—for it is, indeed, one of the injustices of progress that only he who does so drive it home; who makes, as it is said, a discovery, acquires the credit—but they fill their niche in the world's economy and help discovery on.

No more use for the practical man? Is our use in the future to be no more than this—that we are to carry out the orders of the worker in the research laboratory? Surely the history of medicine points quite another moral. What about Bright and renal disease? It might well be wondered how far back in the century we still should be in relation to the malady that bears his name if Bright, the practical man, had not by his clinical observations and his observations in the post-mortem room pointed the clear way to future observation. Others may come after—the chemist, the physiologist, and so on—and point out further facts in the causation of the disease and differentiate from out of one now common group several varieties of distinct diseases, but Bright, the great clinical observer, showed them the way—he led them like Moses to Mount Pisgah, showed them the promised land, and said, Go forward and possess it. In the same way Wilks, who is really the father of all the careful work that has been done in England in the deadhouse, George Johnson, and other early pathologists, taught us more fully the distinctions between the various post-mortem changes. Others, for aught we know, may come after and drive home the further knowledge that this form of disease is due to a germ; perhaps that to some degenerative change; that to a pure inflammation, if there be such a thing. But the earlier observations have still pointed the way and set in process the thought and the line of investigation which eventuate in the final result. Then think of Jenner and Stewart—was there ever a better instance of a practical man than the late Sir William Jenner?—these two by their observations at the bedside and in the post-mortem room "discovered" the differences between typhus fever and typhoid fever, and it may well be maintained that they are the fathers of all that has been added to our knowledge since that day. And very interesting is it, to my mind, to think that typhus fever has practically disappeared from among us by the light of pure hygiene and common sense or ever the great biologists could get a finger in the pie. To find the germ of typhus fever now were but to find a missing link in the imperfect record of disease; unless, indeed, it be now only under the influence of the night. For of epidemics also is it true, "The night cometh in which no man can work."

It is much the same with malaria—a disease that has already disappeared from large tracts of country by the ordinary operation of hygienic laws. And it will be particularly interesting to watch what the bacteriologist will do now that his chance has come of attacking it from the inmost recesses of its origin. Take, again, the observations that have rendered the name of Addison imperishable in the annals of medicine. Addison was a great bedside teacher if ever there was one. He was a man of insight, of presence, and of speech, and by no means what one would now call a great biologist. He also, like Bright, captured a fortress far afield, from which even yet no great advances have been made although many patient workers are striving to open out new ground from his the original focus of discovery.

Another good illustration is to be found in vaccination, for who can doubt that for its usufruct one must count all the work that has been done of late upon the treatment of disease by animal extracts. The great biologists did not elaborate these out of their own heads. They had had the suggestion before them for years. Many a one must have seen the possibilities that this treatment of one of the specific fevers suggested in other directions, but the time was not yet ripe in other ways for what might seem dangerous experiments, and so the discovery, so far as it opened up lines of treatment other than that for the especial diseases, slumbered until Pasteur and Lister came along. Pasteur, by absorbing and regenerating the idea, opened it out and sent it along with all its possibilities in the treatment of microbic disease in general, and Lister helped largely to this end by showing how it could be carried out safely, and also with precision, which was necessary for the formation of reliable conclusions. From these two have come down in ever-increasing volume all the work that has been

B B

done in pure cultures, attenuation of virus, toxins, and anti-toxins, and so on, and although Pasteur was certainly one of the great biologists, Lister is the practical surgeon, and derived his chief inspiration, I imagine, from what he saw in the wards.

And at the risk of wearying you I would fain give one more illustration, and that shall be myxœdema. I take it that there is no disease that has given a greater stimulus to the treatment of disease in modern times than this, and what is its history? Sir William Gull first called attention to it as a retinal state in the adult woman, a description that is strictly accurate. Dr. W. M. Ord worked at its chemistry and gave it the name of "myxœdema." Kocher, a German surgeon, found that in the removal of thyroids for disease his patients became myxœdematous. Mr. Victor Horsley produced the disease experimentally in monkeys by the same practice; and the records of necropsies showed that in those who died from the disease the thyroid body was in a state of atrophy; and Dr. George Murray and Dr. Hector Mackenzie suggested the remedy of introducing thyroid substance into the tissues and the food. A great body of work, and of the most far-reaching effect in all sorts of directions other than those of the one special disease, worked out almost entirely by practising physicians and surgeons from clinical observation.

Now let these few examples serve to show that, at any rate in the past, the man of practice has been the pioneer, and assuredly what has been in the past will be again. The man at the bedside and the worker in the laboratory have each their special work to do. And to my mind the function of practice is to throw light on functional and common ailments, to track disease behind its many feints; to be keen to see in the kaleidoscope of symptoms the one disease that determines all; the distinctions that exist between superficial resemblances; the affinities that link up together things that, maybe, are apparently diverse; to be able to keep the mind constantly on the look out for the straws that tell the direction of the wind, and thus be able to suggest associations to the undiscerning, or lines of profitable research to those who are ready and capable of taking them up. But to do this is often to go far ahead of your facts—it is, indeed, to cultivate the imaginative side of your intellect, and that is to expose yourself, maybe, to the finger of scorn of the so-called scientist. But there is no need to set to work upon a purely imaginative basis; a quick and receptive mental attitude has often ere now got an insight of the future, has set further work going to prove or to refute, and so has acted, so to speak, as the spermatic element in the infant Discovery. Imagination is not necessarily unscientific—it may be science on the edge of a precipice if you like—but carefully handled it is an indispensable link in the chain of research, and it is the link, I think, that you and I are most concerned to use. Many a man can catch and add an idea to the general stock who has neither the time nor the special skill necessary to carry a problem to its conclusion. And at the bedside I doubt if one can be too inductive in the contemplation of disease, the forces of nature are so inextricably interwoven. The delight of our calling is surely not in being a mere prescriber of drugs but in keeping a plastic and sensitive mind alert to note how little details in what we may even judge to be but trivial diseases fit in with, and bear upon, the larger questions of the grouping and the treatment of disease in general; to watch how function is modified here or there, how this or that drug acts in this or that case or individual, how this vital resistance plays you false and that assists you in your endeavour to unravel the true relation between supposed cause and effect, so that in all we may obtain a better knowledge of disease and a better hold on it with each case ended. This is the attitude that constitutes the scientific mind and which renders the practice of medicine a pleasure even amid its constant sorrow and care. The unscientific mind thinks only in terms of cure—I cured this with A and that with B; I did this and I did that. Methinks the humility of the "*Deus volens*," once so common and now almost lost, breathed a more scientific spirit, for it recognised the intervention of unknown values that might interfere with the soundness of our conclusions. And, oh, these hidden quantities! How stimulating they are and how perplexing and inscrutable they are likely to remain. And it is in these so-called trivial diseases, the common objects of the medical shore, that our danger comes of sinking into that complacency—that is, unto death. And yet in each and all of them how much there is that we do not know; how much that if we did know would not only illuminate themselves but many other kindred states.

Let us look for a moment or two at one or two of them. Take the first that comes before me as I think over the subject of this address. A man comes into my room and he tells me that he is so "slack." If I examine him perfunctorily and finding no disease give him a tonic and send him on his way I do all that is expected of me, and so far as he is concerned I may or may not do him any good, but I shall certainly have done myself harm, because there has been no true intelligence in the process and at most I have performed a sort of mental chuck-farthing. If, on the other hand, the complaint wakes up a responsive interest in the listener, how then? The mind sparks out into glimpses of many possibilities, the embers of a common complaint become vivid with life, and slackness then represents to you, perhaps, the effect of a thunderstorm, perhaps a father or a mother with the megrims, or the gout, perhaps a great anxiety, perhaps a fortune ill-gotten in the sense of having been too early sought and won, perhaps a kiln in which the draught induces waste, perchance the dampers keep production low, perhaps some early heralding of grave disease. And then to pass from further possibilities you turn to your other great function of relief or cure. Then one soon learns how completely inefficient are tonics to effect our purpose. And then, again, the mind goes out in questionings as to the nature of nerve force and its method of production, and one wonders whether perhaps, some day, electrical and nervous energy will approach each other more closely; and one longs for a jar of that magnetic vitality which one mind now and then unquestionably seems capable of infusing into another—an influence, it seems to me, that has of late become appreciably more real and conceivable since wireless telegraphy has come within the compass of investigation and experiment.

Let me next take swooning as one of the functional states that is well worth a study and yet one in which our ideas are very elementary, not to say too often erroneous. The common notion is undoubtedly that when a man faints the heart has gone wrong—a cause and effect that are seldom indeed coexistent. Swooning is *cerebral* and not *cardiac* and, as all here well know, it is often epileptic. But this also is but a bald and imperfect statement, for the condition is one that is interesting in the extreme, both as regards origin, affinities, and prevention. For the purpose of this address I have examined my notes of all the cases of swooning that have come under my notice—say in the last 16 years. There are 156 of them. I am sure I am correct in saying that most of them came because they took swooning to mean heart weakness, but only 10 of them had any cardiac trouble of any kind, and even of these in only three or four, if so many, could the heart, though at fault, have had anything to do with the faints. The list shows conclusively the nervous origin of swoons. It is now the overworked and anxious stockbroker who swoons, the neurotic woman, the sufferer from tinnitus aurium, from gouty vertigo, the patient with Ménière's disease, the epileptic, and now and again a case turns up that is rich with suggestion as to the cause of swooning. Here is one. A man, aged 54 years (and that reminds me that I had thought that swooning was an affection of women, but it is not so; in my cases the males slightly preponderate), had been very healthy till lately, but had taken to being very giddy, and one day, walking, he was taken with "a dreadful attack"; he became quite collapsed, and it was with difficulty that they got him into a shop—for he could not move—and gave him some brandy, and after a time his son, who was fortunately with him, got him home. I could find absolutely no disease, but he had a remarkably livid nose and ears, and his fingers were prone to die. And I cannot help thinking that his brain goes blue like his nose and ears, for I have notes of several similar cases—girls who swoon with remarkably blue hands and who have chilblains in cold weather; for example, a girl, 21 years of age, whose feet are always so cold that she requires a hot bottle in her bed. She has suffered from chilblains and of late she had had three or four faints. Here is another note of a woman, 31 years of age, who swoons. She has no headache or drowsiness. She sometimes vomits after insomnia. She has a good deal of close brain work and cold extremities always. I found no disease, but a peculiar erythromelalgic or Raynaud-like condition of the hands. I know of others who swoon from a violent cough. Now couple this experience, which I say is by no means uncommon, with the following observation by a medical friend upon his own person. I had been writing to him about a doubtful case of epilepsy and he writes back: "It will be useful if I give you my own personal experience."

As an overgrown boy of 19 or 20 I went to skate one very cold winter's day, left home, walked half a mile through the cold, and stood in the station waiting-room before a warm fire. The next thing I was conscious of was finding myself lying on a bench feeling awfully ill. I was told that I had suddenly fallen to the floor and almost knocked down a burly man in my fall. I have often since then experienced a tendency to swoon on coming out of the cold into the warm. My idea was that the sudden relaxation of the cutaneous vessels, previously strung up by the cold, was the cause of this fainting, the supply to the brain being for the moment switched off. Once or twice on such occasions I have found my left thumb twitching, and have had to beat a hasty retreat and keep a sharp grip upon myself. For treatment, in others, I trust more to valerian and valerianates than to bromide."

This case seems to me to be an unusually suggestive one, for no doubt the phenomena do seem to correspond to an occurrence such as is here suggested, and when we remember that what might seem to be very parallel occurrences are met with outside the body—where, though even here but poorly, they can be studied or, at any rate, observed—such as Raynaud's disease, erythromelalgia, dead fingers, and so on—it seems not unreasonable to suppose that we have a common group of diseases of the peripheral circulation which in the future we may be able to control by drugs. I would lay stress on this because this group has a close relationship to epilepsy, whereby its importance is considerably enhanced. For surely the great desideratum in this dread disease is a something that shall in a moment give the sufferer a greater grip over himself or still the rising storm. To avert an occasional explosion we now benumb the activity of the cerebral centres for long periods together, which cannot but be a harmful and wasteful procedure.

Closely related to this is another condition that strikes me as one that the practical man can advance by careful clinical observation—it is vertigo. You are frequently called upon to prescribe for giddiness, and in books you find it described as a symptom that is sometimes due to ocular and sometimes to aural disturbances, which does not seem to help one much. Giddiness, like swooning, is always a cerebral phenomenon. Sometimes it is a mild malady that owns some passing cause probably of toxic origin. In old people it is said to be chiefly gouty, and then it is never of much importance, although it often distresses its subject for fear that it may indicate commencing brain disease, a threatening of a stroke, and so on, which it hardly ever does. Sometimes it is a grave affection, associated then with the severer forms of migraine, with deafness and tinnitus. In most of these the room suddenly goes round, the ground seems to rise rapidly, till it seems to strike one in the face, and then the person falls. So suddenly do some of these attacks come on and pass off that it is hard to say what has happened—whether, indeed, there has been a temporary swoon or not. Some of these cases are, no doubt, closely akin to epilepsy, but their real nature is sometimes very puzzling. Not so long ago a lady was brought to me for an attack of which the following is a *résumé*. She was well past middle age; she had had a tumour removed from her breast, which was thought to be cancerous but proved not to be so. She was suddenly seized in the middle of the night with intense pain in the region of her heart and all the use in her legs went. The attack was over so quickly that she had not time to call. She had another attack while waiting in the street. Suddenly, without any pain this time, her legs gave way, and she slid down on to the pavement. She described herself as panting, shaking all over, everything falling from her hand, but she did not lose consciousness. It was impossible to be sure what was the nature of these attacks, but, on the whole, I inclined to their being cerebral and not cardiac. She returned to see me some five weeks later, having had no more attacks, but she still had a constant pain in her heart though noise worried her, and her head was "all of a whirl." The heart was excitable, but no more. After a few more weeks she had an undoubted epileptic fit, and I now hear that there are signs of a cerebral tumour. So that you see in the subject of grave giddiness a wide range of diseases is involved—at one end migraine and then in linked series come Ménière's disease, epilepsy, and cerebral tumour to arouse the interest and to keep the mind alert. Even in the milder forms that occur in old people and are called "gouty" there is this of interest—that you can never be sure whether remedies will cure in any given case, for vertigo is rather prone to hang

about, to the worry of the sufferer and to the detriment of our reputation. It, like swooning, must, I think, be largely a matter of peripheral spasm; it also is a common object of the medical shore; the general practitioner is the one under whose ken it mostly comes; he has only to observe and to think about his many cases and he can hardly fail to add to our knowledge of the subject.

And having spoken of swooning and vertigo and taken the view of their nature that I have done, it is natural that I should pass on to other conditions of the peripheral circulation that you must see many of and therefore have some opinions about. And first in this regard let me say a word about the pulse. Think of all the pulses you have each of you felt; if each time you feel a pulse you do it with your full understanding, what an extensive experience is comprised within these four walls to-night and how much you must know about many moot conditions. But I have no doubt whatever that were this a discussion I could at once traverse one of the innate ideas of many by saying that I am no great believer in the *weak* pulse. I am often told by Mr. A or Mrs. B that he or she has such a very poor or weak pulse. And the implied suggestion that almost invariably is conveyed in that fact is that it is an indication of the impaired vigour of the heart that is behind it. And it seems reasonable enough. But think about it; and is it so? I will not say that he who sets store by a weak pulse and treats his patient upon the deductions that spring therefrom is altogether wrong; but I will say this, that for one case where a weak pulse is an indication of disease there will be a hundred in which it is no indication at all, and I think that I am more often right in saying, when anyone comes to me, and tells me that his medical attendant says he had such a weak pulse, "A very good thing for you! a weak pulse is an earnest of longevity, and you will not die from apoplexy"—save only that you must be sure about the weakness, for a weak pulse is sometimes a strong pulse—that is, a high tension pulse—but because it is a small pulse it is mistaken for a feeble pulse. Now I have thought over this matter over and over again, making the preliminary admission that I must be wrong in my opinion, for a weak or feeble pulse must be a valid indication of the condition of the heart. And yet the more I think of it the less can I see in the smallness of volume of a pulse any reliable indication of the vitality or nutrition of the heart. It is so sometimes, no doubt, but for my own guidance this sometimes has been chiefly in cases of acute illness, such as fevers, where in the course of the daily watching you have found the pulse alter and become soft or small and unsteady, an alteration that probably takes count of several details and not of the mere matter of feebleness.

When I look back upon all my experience of weak and feeble pulses, if I except the case of the very old and the dying where the extreme compressibility makes even observation difficult and goes with what is obviously extreme exhaustion—a condition that is certainly not so very uncommon—there is only one case that stands out in my memory as a pulse where I was sure that its weakness betokened a danger that was not otherwise discernible. And that case is instructive, for the patient was not yet old. He was sitting up in bed and in no distress. He was able to talk to us in a natural voice and with clear and vigorous intellect. His medical attendant had seen him in two or three attacks of sudden syncope when on merely moving out of bed he had gone grey and pulseless and appeared to be dying and I had seen him after one of these attacks when his pulse was so soft as to be hardly discernible and it was obviously sometimes better and sometimes worse within the few seconds of the examination. There was nothing very special about the heart—I do not think that there was any murmur—but we were convinced from his attacks and from the state of the pulse that there must be some very serious structural change in the muscular wall of the heart and we prognosticated accordingly. And so it fell out that there were three of us at the next day's consultation, and being interested in this question of weak pulses I endeavoured to extract from our senior what value he attached to this pulse from which I had drawn so grave a verdict, and I distinctly recollect being disappointed at his not taking much notice of it and drawing his conclusions (decidedly more favourable than we had come to) entirely from the state of the heart. I am sure of this, that if ever there was a pulse denoting a desperate state of the heart this was that case, and the patient died within 24 hours in

another of his attacks; and yet here was one of us paying little heed to the pulse, which clearly means that weakness for him had very little meaning. I hope, therefore, that no one listening to me to-night tells his patients that they have a weak pulse and a poor circulation, leaving them to imagine that their pump is wearing out—a conclusion that seems very reasonable and in 999 times out of 1000 very wrong. Thus I doubt if I should ever order a patient stimulants on the mere strength of a feeble pulse. I should need to take stock of many other points besides the mere one isolated symptom. Perhaps one would except certain pyrexial states, for in these one may suppose that one approximates nearest of any to dealing with the muscular power of the heart direct, for the pyretic state is liable to paralyse the subsidiary forces of the circulation and thus the peripheral current may become a reliable gauge of the condition of the heart. But possibly some may think that as I take so little stock of the feeble pulse as an indication of the state of the heart I must apply the same reasoning also to the strong pulse, and equally ignore the value of that. But I do not do anything of the kind, for I suppose that the peripheral control of the circulation as regards diminution is a much more direct one than its power of propulsion and, moreover, a strong heart may possibly overcome or modify the forces of the peripheral circulation, and so what I deny to the feeble pulse I allow to the strong pulse, for I think that it is a very valuable indication of the work that the heart is doing. And yet, as if to bear out my present contention that the pump and the conduits are in a large measure independent of each other, I have occasionally come across cases—I wonder whether anyone here has noticed the same fact—where the pulse has been a full hard pulse suggesting a labouring large heart, and when one turned to that organ one has found, as far as one could gauge it, that it was a poorly-acting and possibly feeble organ. Such cases are by no means common and they are not easy to explain, but I suppose that they are due to some capillary obstruction which, while inappreciable to the onlooker, is sufficient to overfill the vessels behind and perhaps to hamper the central organ. It is also possible that the heart, while giving no signs of enlargement or of labour, is yet involved in the one and the other, for it cannot be too often insisted upon at the present day that it is sometimes impossible to say if the heart be enlarged and that feeble sounds are hardly of more value than a feeble pulse. Take also that very interesting matter of persistently slow and quick pulses—a fit subject truly for an active-minded man. How little we know about them except the appalling fact that no remedies that are at hand will, for certain, make a quick heart go slow or a slow heart go quick. What a confession of incompetence, but it is the fact, digitalis and a few other drugs notwithstanding. Nay, what is more, we deliberately turn away from what little we might know and talk and act in that contradiction to it. No fact, for example, is more certain than that the most common cause of a tachycardia is cerebral excitement, no fact is more certain than that a common cause of bradycardia is cerebral disease, and yet we talk of either as a disease of the heart, and attempt to control it by remedies that act upon the heart. Bradycardia may perhaps sometimes be dependent upon a dilated and diseased muscle, but I expect it is far more often due to some local disease or toxin in the bulb which we as yet know nothing about.

Passing from these to murmurs produced in the cardiac area, let me speak not so much about special murmurs as about the observation of murmurs. No class of cases is more common in general practice, and if we only sit ourselves down with a level head to observe these unnatural sounds you that have the chance of more or less continuous observation of cases over a long range of time may find it possible to add much to our knowledge. First, as regards their disappearance: it is generally and reasonably held that certain murmurs, the hæmic, for example, disappear: but there are plenty of these innocent or non-valvular murmurs shall we call them? that do not go, for all our treatment, and yet the patient is much the better in general health and maybe seems quite well. Next, as regards position, we are accustomed to think in terms of four valves with a very occasional interpolation of a congenital exception, and outside this our thoughts hardly ever roam. But if you observe for yourselves, without any undue subservieney to the opinions of those who have taught you, you must come to the conclusion that murmurs are by no means uncommon where the characteristic souffle is exactly like the murmurs that

you are accustomed to think are caused by valvular disease of the common kinds and yet which you cannot quite fit in with any of them. It seems to me to be difficult to escape the conclusion that exocardial murmurs may simulate endocardial ones very closely and that they are much more common than most of us are inclined to admit. One other point I am inclined to insist upon is the variability of murmurs. I am not now alluding to the case where, the patient being seriously ill with heart disease, a murmur is sometimes present and sometimes absent—you all know of these cases and are accustomed to draw certain inferences therefrom as to the condition of the heart muscle.—I am alluding to a commoner and less noted variability where the murmur changes or disappears in the course of one examination and in response to some ordinary change of the position of body. Of the first class there is the common case of the nervous man or woman under examination where the heart is beating very rapidly and a loud murmur is heard with the first sound more or less in the position of the impulse. You listen on and the heart quiets down and the murmur quite disappears, to reappear, however, if anything again disturbs the heart in the course of the examination. The other group is where examining the patient standing you hear only the natural sounds of the heart; you put him recumbent on the sofa and the heart becomes cantering in its action with a more or less loud systolic murmur about the region of the impulse. Sometimes it is the other way about, but much less often so, where nothing is heard in the recumbent position and a murmur over the impulse when the patient is sitting or standing. Now I gather that there are those who think that a bruit heard under what may be called these partial conditions is nevertheless likely to mean some weakness of the muscle, and therefore to be, at any rate for the time, a real disease of the heart. I, on the contrary, should contend that murmurs that alter much in character, or come and go in accord with a change of the position of the body, are seldom of any importance. For my own part, I think that many of them must be produced outside the heart and in the lung adjacent to the impulse, and I think so because there is another very common systolic murmur that is often heard in women and in anyone who is not of the robustest type of physical development, which cannot, I think, be anything else from the characteristics that it shows. It is a systolic murmur like the others, and it is heard at the impulse and round into the axilla and even into the back sometimes. But its peculiarity is this, that it is heard in puffs only, two or three together, each puff quite distinct from the others, nearly always either at the end of inspiration or of expiration, and at other times the sounds are absolutely healthy. It certainly has no significance as regards the heart.

There are yet one or two other common conditions that may not inaptly be mentioned here in connexion with the group of circulatory disorders from which I have drawn my illustrations to-night. One of these is what I can only call puffiness. I am sure that it is a condition you are all familiar with, it is such a very common complaint. I dare say some might think that it is a symptom met with in hysterical women, but I think that opinion would be derived from the mood of complacency that I have already alluded to. I consider puffiness to be a real condition, although I am quite ready to admit—indeed, this is to me its real feature of distinction—that it is very difficult to substantiate this by our rough tests of pitting. I remember some years ago a woman who came to me several times complaining of this puffiness, and I could never make out that there was any real oedema. It was chiefly round about her eyes, but before very long it grew worse, and then there was no doubt that the case was one of myxœdema and it developed into a well-marked case. Naturally I have never forgotten that mistake, and whenever I hear of a woman complaining of puffiness, myxœdema is my first thought. But it is by no means always an indication of that disease. It is sometimes an indication of anæmia, and sometimes it is a curious state that is impossible to explain. Take the last case that I have in my remembrance. A woman who has lived a healthy life, and who has been healthy, slowly begins to lose her energy and to feel tired, and to get, as she expresses it, “so puffy” and so fat. Her eyelids are particularly noticeable, but it is not alone these, for her hands and feet feel stiff and uncomfortable. I examined her several times and I could not detect anything certain, but I *did* think that her complexion was a little pink and yellow, and that perhaps the lower

lids were a *little* puffy. I thought from her appearance that perhaps there might be some myxœdematous state behind it, and therefore put her on thyroid tabloids, but I cannot say with any striking result, although she expressed herself as better. I examined her urine, and found that it contained a little albumin—a mere trace. She got a little better but by no means well, so she was sent to a water cure, and there she lost all her feelings of fatigue, regained her walking powers, the albumin disappeared from her urine, and she came back quite well. So she continued for many months—till the other day, in fact—when back she came again on account of the same symptom, that she was again becoming puffy, “all over the body” as she expressed it. And again I failed to find anything that I could recognise as œdema, but again there is a return of a trace of albumin in the urine. And I have no doubt that her sensations are a true intelligence to her, that I cannot approach in delicacy. But what is this puffiness that she detects with such precision? I am inclined to think that it is some lymphatic or capillary difficulty, and that, owing to some fault in her juices, the parenchymatous processes of supply and absorption do not go on quite so readily as in health; and that this difficulty is recognised by the patient as a certain stiffness of the tissues. You have all, I doubt not, seen similar cases, for they are not by any means uncommon; and for myself I think that they are of considerable interest and well worth an attempt to unravel them when they occur. I once saw a little infant who suddenly became œdematous all over the body. There being no albumin in the urine, I turned to the diet to see if in that I could find any cause, and then I was told that for some reason or other, I forget now what, the child had been cut off all its milk and had been fed upon extraordinary quantities of broth.

And, mind you, it is out of the habit of closely observing common things that new diseases come. A new disease is always old, for even if, as I myself believe must be the case, diseases alter as their environment, this can only be a gradual process; new maladies do not jump into existence, and long ere they are discovered they have lain neglected or unrecognised before our faces. Cases of osteitis deformans, that curious enlargement with softening and curvature of the bones, identified now and for all time with Sir James Paget's name, were lying in our museums and records years before he signalled them, and out of Paget's description has, I doubt not, come a further interest in the bones and a fuller description, almost amounting to a like new discovery of acromegaly. Infantile scurvy, now associated with Sir Thomas Barlow's name, is to be found as an isolated case described by Sir Thomas Smith as “hæmorrhagic periostitis” at a much earlier date. Actinomycosis of to-day is surely the same disease described long ago by Dr. Vandyke Carter as “Madura foot.” And who can doubt that when the time is ripe the same careful observation along the wayside of medicine will separate out other new diseases as that in the past has done? It is hardly wise to forecast the future in this respect, but it does not require much prescience to foretell that the field of pyrexial disorders is as yet by no means worked out, and for that reason I am glad to read of “the fourth disease” because it shows that a careful observer has his eye along this line and is attempting to re-open a but half-worked mine.

I do not think that we are enough alive to this search for new diseases. A good many of us are inclined to say “Fudge!” if such a thing is suggested, but the idea at any rate is a most energising one. I saw but the other day what was to me a new disease. It was in a large school in which both measles and influenza were rife and many children were down with each. In the course of these three boys at least, developed a markedly hectic fever with a deep coppery efflorescence of the skin which soon passed on into a condition of dermatitis not inaptly described as “crackling.” But in addition to this there took place a sudden development of a fine capillary bronchitis that rendered the patients quite cyanotic and killed two children, one in less than 12 hours and the second in a somewhat longer time. In the third case recovery took place. I suppose it would be enough for most people to say in general terms that these children all suffered from an acute septic poisoning, and there let the matter rest, but I think that the cases become much more interesting if we let our minds roam over the supposition, not unlikely to be true, that we had here a new disease, and possibly a hybrid between influenza and measles. There is, at any rate, this much to be said in favour of this

hypothesis, that there are few diseases that could be named that, if they could be made to breed together, would be likely to produce a more uncanny offspring, for both are of the worst possible febrile type. All *old* diseases, too, become of a sort new in their personal form, by reason of the individuality that they then put on, and I think that epidemics have many a curious and instructive tale to tell, if only we could read, of this production of sports and thus new diseases. But I suppose that, like sports, they most often show their inveterate tendency to reversion, and thus we are not heavily burdened with fresh ailments.

One other condition also will I mention, because it has, to my mind, the making of a new disease within it, and this is what has generally been introduced to me as “phlebitis,” but I am by no means sure that all the cases which I have seen and which have been supposed to be of this nature are rightly included under one heading. The commonest form of the disease, and perhaps that to which there is the least exception to be taken, is where a man or a woman is suddenly taken with intense pain in one calf, some swelling that perhaps quickly subsides, and the complaint is said to be an attack of “gouty phlebitis.” A case of this kind, taken as it stands, I should hardly be prepared to question, and very likely the name correctly conveys the nature of the malady, but such cases by no means always end up thus simply. It has several times happened in my experience that after being laid up for four or five weeks with a leg of this sort—the length of time being determined by the fear of the medical man that if the leg be allowed to droop or move a plug will be dislodged and pulmonary embolism result—suddenly there comes a similar attack in the other calf, and then another six weeks is required; and I have known the process to be repeated in other parts of the body and limb, and a period of months to be occupied in keeping the patient out of danger of embolism. In one of these cases the so-called vein process was accompanied by pain and swelling in some of the joints, and after being ill for many months the patient ultimately plumped out in her cellular tissues in such a way that she was supposed to have myxœdema. She was accordingly treated with thyroid extract but without much, if any, result, and when a committee of us sat upon her not long afterwards the body of opinion was against her having myxœdema, and I think no one was bold enough to give the disease a name. Another case I well remember, that also began in the calf of the leg, as I have described these others to do, and then other attacks followed in one and the other leg, but what was most remarkable was: that spread about, I think, both legs, but chiefly the right, in the course of the long saphena veins, there were large, hard, red, intensely painful, bubo-looking masses that I felt sure would require to be opened. I suggested that a surgeon should be called in for that purpose, but after giving a dreadful lot of pain for several weeks they all took their departure by natural effort. At the onset of this case I fell in with the routine diagnosis of phlebitis, but the subsequent course of events convinced me that it was of a different character and that it was in reality a lymphangitis. I am, indeed, now inclined to doubt whether there be such a disease as multiple phlebitis, and to think that we have a disease of the lymphatics that has not as yet received any adequate attention.

And then there comes the great question of the treatment of disease. It also falls well into line with all that I have said as regards cultivating a habit of minute observation, but I should make this one qualification—viz., that whereas I have contended that in suggesting to oneself possibilities as regards the causes and affinities of the processes of disease one can hardly be too imaginative, I should like to insist that one cannot be too reticent in the advocacy of remedies; it is hardly possible to be too critical in our judgment of an apparently favourable result. But with this damper on special enthusiasms how alive with interest becomes the most vulgar subject. Contrast the two systems of the treatment of disease—the scientific, shall we call it? and the penny-in-the-slot system in any common ailment—let us say constipation. By the one we set ourselves to determine as near as may be the cause of the malady, and that takes us over the man's whole life, his work, his exercise, his recreation, his nervous energy, his food, his very temperament and being, and one rises from the study a physician of larger mind and a more finished competency to treat disease. On the penny-in-the-slot plan we may hit out a success, but we do not reach the low level from which I started, for we are not

even indispensable, for the patent-pill man might have done as well or better.

Such, then, are some of the many subjects that might be selected to exemplify the constant need that there is of a never-relaxing scrutiny of the common aspects of practice. And in parting with my subject let me say that although practical medicine is essentially scientific both as regards its means and aims it is possible, alas, to degrade it to a trade. Not often this in the present day, when all men are so well educated and for the most part keen in their work. But we take it up with an obligation, and that is to prove all things as far as may be possible, and then to record our thoughts by means of such societies as this. I know that after a day of toil from very weariness of the flesh it is difficult indeed to put pen to paper, or even to have any thought at all, but I believe the main difficulty to be other than this—viz., that so many are unduly critical of the amount of their knowledge. Remember, then, what you are. Assert yourselves, and take your proper precedence by virtue of your right, as being men engaged all day long in contact with active disease. Speak up, and be assured that what you have to say is well worth listening to: there is far too prevalent a tendency to silence the individual judgment in face of the last new dictum of science, and thus it is that many a poor gem passes muster for lack of the polish that criticism would give, and which the mature experience of the practical man is so well able to afford.

### MODERN METHODS OF VACCINATION AND THEIR SCIENTIFIC BASIS.<sup>1</sup>

By S. MONCKTON COPEMAN, M.A., M.D. CANTAB.,  
F.R.C.P.,

LECTURER ON PUBLIC HEALTH, WESTMINSTER HOSPITAL.

I DESIRE in the first place to express my appreciation of the compliment you have paid me in asking me to open a discussion on modern methods of vaccination. The subject is one which cannot fail to be of special interest at the present moment, seeing that for the first time for a considerable number of years London is experiencing an epidemic of small-pox which, although thus far of insignificant extent relative to the total population, may not improbably, with the advent of winter, assume grave proportions unless energetic measures for its suppression are adopted. I desire to include under the title that has been chosen for the subject of discussion all methods that have tended to increase the amount and to improve the value and efficiency of vaccination, especially as carried out under official auspices at the present day—to include, therefore, all methods, experimental, legal, and administrative, which have been, and are being, employed with the objects that I have mentioned. But in order the better to appreciate the precise value of such modern methods it is necessary in the first instance to digress a little in order briefly to review, under these various headings, the history of vaccination from a period antecedent to the time when the operation first gained official recognition in this country.

As is, of course, well known, the introduction of vaccination dates from the publication in 1798 of Dr. Edward Jenner's historic pamphlet, the original draft of which had shortly before been rejected by the Royal Society. It is doubtless true that Dr. Jenner had been to some small extent anticipated by Jesty and others in the employment of the virus of cow-pox as a prophylactic against small-pox, but he it was who first realised the possibility of carrying on the disease through a series of human beings, by transferring the contents of the vaccine vesicles from arm to arm, and who by his strenuous advocacy of the methods introduced by himself first brought the matter prominently before the public. Early in the following year (1799) an extensive series of public vaccinations were initiated in London, mainly as the result of which Dr. Jenner was enabled to state in 1801 that "upwards of 6000 persons had been inoculated with the virus of cow-pox, and that the far greater part of them had since been inoculated with that of small-pox and exposed to its infection in every rational way that could be devised,

but without effect." For this rapid extension of the practice of vaccination Dr. Jenner was not a little indebted to the activity and enthusiasm of Dr. Pearson of St. George's Hospital and Dr. Woodville of the Small-pox Hospital, who, when Dr. Jenner's stock of original lymph had come to an end and opportunity for replenishing it did not immediately offer, were enabled, as the result of their discoveries of outbreaks of cow-pox in various parts of London, to start independent series of vaccinations. In 1802 Dr. Jenner's discovery was brought to the notice of the Legislature, with the result that a committee of the House of Commons, after examining a number of witnesses eminent in the profession, issued a report entirely corroborative of Dr. Jenner's statements. In 1806, again, in consequence of an address to the King voted by the House of Commons, the Royal College of Physicians of London were instructed to inquire into the matter. Concerning the outcome of this inquiry, which extended over some nine months, it is stated in the Appendix to the Report of the Select Committee on Vaccination of 1871 that "the College of Physicians feel it their duty strongly to recommend the practice of vaccination. They have been led to this conclusion by no preconceived opinion but by the most unbiased judgment, formed from an irresistible weight of evidence that has been laid before them." Sir John Simon has placed it on record that in consequence of this report, which was presented to the House of Commons in July, 1807, "the public mind was apparently quite satisfied on the subject, and from this period begins to date the almost universal vaccination of children of the educated classes in this country."

In 1809 the so-called National Vaccine Establishment was founded, of which Dr. Jenner was first appointed Director, although he shortly after resigned the post. From this period onwards, in spite of a certain amount of opposition, the practice of vaccination became gradually more popular. But notwithstanding the fact that the value of the operation received ample recognition from Parliament, by whom its discoverer was substantially rewarded, it was not until the year 1840, in which the first Vaccination Act was passed, that the subject was dealt with by legislative enactment. By this Act, which was to some extent amended in the following year, every inhabitant of England and Wales was afforded the opportunity of obtaining vaccination at the public cost, although the question as to whether any person availed himself of its advantages or not was left entirely to his own option. Another important provision of this Act was that the operation of small-pox inoculation, which prior to the introduction of vaccination had obtained a considerable hold on the populace, was now prohibited, the transference of small-pox virus from one person to another being made a penal offence.

Not until 13 years later, in 1853, did vaccination become compulsory. The Act passed in this year made provision for the establishment of stations in each of the districts into which guardians and overseers were required to divide their unions and parishes in order to afford increased facilities for vaccination of the poorer classes. At these stations medical officers were to attend to perform the operation, and again for inspection of the result, and parents or others having charge of children failing to cause them to be vaccinated, or subsequently to vaccination omitting to have them taken for inspection, rendered themselves liable to a penalty. Certain further enactments, to which specific reference is unnecessary, came into force in 1852 and 1861. Six years later, in consequence of certain difficulties having arisen, more particularly in regard to the enforcement of penalties, a Bill to consolidate and amend the law relating to vaccination was brought before the House of Commons. This, after reference to select committees of both Houses, was passed and received the Royal assent on August 12th, 1867. Hardly, however, had it become law before strenuous opposition to its provisions was raised, Parliament being eventually petitioned to repeal it. Under these circumstances a Select Committee to which reference has already been made was appointed in the session of 1871 to inquire into the operation of the Act. As the result of careful consideration of the evidence brought before them the committee reported that in view of the great, though probably not absolute, protection afforded by vaccination against attacks of small-pox, together with the almost absolute protection against death from that disease, it was the duty of the State to endeavour to secure the careful vaccination of the whole community. They were further of opinion, however, that multiple penalties should not be imposed in the case of the

<sup>1</sup> A paper read before the Royal Medical and Chirurgical Society on Dec. 10th, 1901.

same child. These suggestions were embodied in a Bill which passed the House of Commons, and after amendment in the Upper House, involving some disagreement between the two legislative assemblies, became law in 1871. By this Act the Local Government Board was substituted for the Poor-law Board and the Lords of Her Majesty's Privy Council in the administration of the Vaccination Acts, and the powers of the Board were extended. Under the provisions of this Act and a further Act of 1874 the Local Government Board in October of the latter year issued an Order regulating the appointment, tenure of office, duties, and remuneration of vaccination officers and also the institution and conduct of proceedings by them. In February, 1887, an Order dealing with the duties of public vaccinators was issued by the Board, and in February of the following year (1888) yet another Order altered the age-limits at which revaccinations could be performed at the public expense.

Meanwhile, however, opposition to vaccination had been steadily increasing, and the administration of the Vaccination Acts became more and more difficult. Thus, although in the year 1872, the first year for which complete returns were made after the passing of the Act of 1871, the number of children in England and Wales whose vaccination was not finally accounted for amounted to but 5.1 per cent. of the total number of births, and the same percentage was unaccounted for in 1883, subsequent to this date the percentage of cases not fully accounted for mounted gradually higher and higher. It was under these circumstances that Mr. Ritchie, the then President of the Local Government Board, came to the conclusion that further investigation of the whole subject from every possible point of view was desirable, and accordingly, in May, 1899, a Royal Commission was appointed, consisting of 15 members, under the presidency of the late Lord Herschell. The terms of reference were as follows: to inquire and report as to (1) the effect of vaccination in reducing the prevalence of, and mortality from, small-pox; (2) what means, other than vaccination, can be used for diminishing the prevalence of small-pox and how far such means could be relied on in place of vaccination; (3) the objections made to vaccination on the ground of injurious effects alleged to result therefrom, and the nature and extent of any injurious effects which do, in fact, so result; (4) whether any, and if so what, means should be adopted for preventing or lessening the ill-effects, if any, resulting from vaccination, and whether, and if so by what means, vaccination with animal vaccine should be further facilitated as a part of public vaccination; and (5) whether any alterations should be made in the arrangements and proceedings for securing the performance of vaccination, and in particular in the provisions of the Vaccination Acts with respect to prosecutions for non-compliance with the law. After sittings extending over a period of six years the Royal Commission published their final report in August, 1896. Once again the value of vaccination as a protection from small-pox was re-affirmed, the actual amount of such protection being declared to depend on the efficiency and thoroughness of the operation and its repetition after an interval of from seven to 10 years. Injury following on the operation was declared to have been insignificant in the past, and under better precautions which should be adopted in the future was likely to disappear completely. Certain suggestions also were put forward as to the best means of popularising vaccination and as to alterations in regard to the infliction of penalties on defaulters and the affording of a loophole to the "conscientious objector."

Before the Royal Commission I had the honour of giving evidence, mainly in reference to the outcome of research work which I had been carrying on for several years previously. This work had dealt with methods of testing the potency of various kinds of lymph, whether of human or bovine origin, and its relative protective powers against the virus of small-pox, and more particularly with the question of the purification and preservation of vaccine lymph derived from the calf. Years before, the occurrence of certain fatal cases of erysipelas following on vaccination in the practice of the then public vaccinator at Norwich, concerning the origin of which an official inquiry was held at the time, had, boy though I then was, made a great impression on me. When commencing work on the subject of vaccination the remembrance of this unfortunate event caused me to turn my attention to the possibility of avoiding the accidental transference of erysipelas and other diseases from one child to another, in the operation of vaccination, by the substitution of some preparation of animal lymph for the arm-to-arm

method of vaccination with human lymph which, prior to the passing of the Vaccination Act of 1898, was the only method officially recognised outside the metropolis. On making inquiry into the matter I found that there prevailed very commonly an idea that the use of crude calf lymph was undesirable, for the reason that it "took" more strongly than human lymph, that, in other words, more reaction and more generally "bad" arms were believed to be likely to result in persons vaccinated with lymph of bovine origin. In the course of a lengthy series of bacteriological inoculations of different culture media, from various samples of vaccine lymph, carried out originally in the hope of isolating the specific contagium of vaccinia I found that my culture tubes were apt to show abundant growth of micro-organisms which proved to be in no sense peculiar to vaccine lymph, consisting in part, indeed, of forms apparently identical with certain microbes commonly associated with suppurative processes. Moreover, a further point was noted that in plate cultures inoculated from specimens of fresh calf lymph the number of individual colonies which resulted was almost invariably much greater than in similar plate cultures, the nutrient medium of which had been inoculated with an equal quantity of fresh human lymph. And it appeared to me not improbable that this fact might have relation to the observed tendency of calf lymph to "take" strongly to which I have already referred, and might be due in turn to the greater difficulty in keeping clean the skin of the calf as compared with that of a child. The further fact was also noted that when vaccine lymph of either bovine or human origin was stored for any length of time in capillary glass tubes, the opacity which usually resulted after a longer or shorter period (an occurrence usually associated with deterioration of the efficiency of the lymph for purposes of vaccination) was caused, in large part at any rate, by an enormous multiplication of extraneous micro-organisms, which found in the serum of which the liquid portion of the lymph consisted a favourable medium for their continued growth and multiplication.

With the object of obtaining, if possible, inhibition of these extraneous micro-organisms without injuriously affecting the specific contagium of vaccinia, and thus providing myself with material of more hopeful nature for the purposes of my research, I carried out, some 12 years ago, a series of experiments which were first demonstrated to the International Congress of Hygiene in 1891 and subsequently to the Royal Commission. The results have since been set out fully in the Milroy Lectures for 1898. To these experiments, therefore, it is unnecessary for me on the present occasion to refer in detail. Suffice it to say that eventually the desired result was obtained by submitting the epithelial pulp of the vaccine vesicle, after careful trituration, to the continued action of a sterilised 50 per cent. watery solution of chemically pure glycerine for about four weeks, such treatment having the effect of at first inhibiting, and ultimately destroying altogether, the numerous extraneous micro-organisms originally present in the lymph material. Later it became apparent that such an emulsion, if preserved and stored under favourable circumstances, of which a low temperature and protection from light are of special importance, was usually capable of retaining its efficiency as vaccine unimpaired for considerable periods. Still further investigations proved that not only was it possible to kill off all the bacteria ordinarily to be found in crude lymph material, but also the streptococcus of erysipelas and the bacillus of tubercle, even when for experimental purposes these micro-organisms had been added in relatively huge quantities to the lymph-pulp prior to glycerination. Thus was gradually elaborated the method of ensuring the bacteriological purification of vaccine lymph to which the Royal Commissioners make reference in their final report, and which as the result of further investigations carried out at their suggestion on behalf of the Government has now been officially adopted in this country for the purposes of public vaccination.

In order to make adequate provision for the manufacture of glycerinated lymph on a sufficiently large scale it became necessary to revise and largely augment the arrangements previously in force under the auspices of the Government. Thus the Animal Vaccine Establishment in Lamb's Conduit-street, which had been founded in 1881 under the direction of the late Sir George Buchanan and Dr. Cory mainly for the performance of vaccinations direct from calf to arm, was entirely renovated in order to comply with modern aseptic requirements and provision was made for the accommodation

of a largely increased number of calves. Also additional premises were leased from the British (now the Jenner) Institute of Preventive Medicine and what are now known as the Government Lymph Laboratories were founded. My late official chief, Sir Richard Thorne, and I had previously, at the instance of the Government, made a tour of inspection of the principal vaccine establishments on the continent, more especially those under Government control in Germany, where we found that the methods devised by myself had already been adopted. As the outcome of the practical experience thus acquired, supplemented by the results of a somewhat similar, although less extended, series of visits made by Dr. F. R. Blaxall subsequently to his appointment as bacteriologist to the Department, the laboratories were equipped as far as possible with everything in the way of apparatus and accessories that appeared likely to prove useful in commencing operations on a large scale. Exactly how large that scale was to prove, however, we hardly realised at the time, and very considerable augmentation of the modest staff with which the work was commenced and large expenditure for the installation of additional instruments have been found necessary, in order to ensure the enormous demand for lymph being met as promptly and efficiently as is now invariably the case.

The methods employed by the Government<sup>2</sup> in the production, preparation, and storage of vaccine lymph and the work performed by the staff may briefly be described as follows.

1. *Vaccination of the calf.*—Calves of suitable age (from three to six months), breed, and condition are placed in a quarantine stable for a week. Their health being ascertained to be satisfactory they are transferred to the Animal Vaccine Establishment. Each calf on admission is examined as to its general health, is weighed, and its temperature taken, a record as to these points being kept. When required for vaccinating purposes the calf is strapped to a large tilting table, and the lower part of the abdomen, extending as far forward as the umbilicus and backwards into the flanks, is carefully shaved. This shaven area is first washed with a 5 per cent. solution of carbolic acid or lysol, then well syringed with tap-water, and finally cleansed with sterilised water. The moisture from such washing is removed from this shaven area, and from the adjacent skin, by means of sterilised gauze sponges. By these means it is found that this area of skin can be freed from micro-organisms, as evidenced by absence of growth on surface agar-agar or gelatin culture media inoculated with scrapings. The calf is then vaccinated with glycerinated calf-lymph introduced into the skin in numerous parallel linear incisions by a sharp scalpel, previously sterilised, which is dipped from time to time in the vaccinating fluid. The incisions are designed to penetrate the epidermis and to open up the rete malpighii, if possible without drawing blood, and as they are made additional glycerinated lymph is run in along the whole length by the aid of a sterilised blunt instrument, such as an ivory or bone spatula. The inoculation of the incisions is effected immediately they are made, otherwise the lips of the wound are apt to swell and to close the opening. After vaccination the calf is removed from the table and is then so stalled in a stable as to prevent any injury to the vaccinated surface. The temperature of this stable is not allowed to fall below 60° F.

2. *Collection of the vaccine material.*—After five days (20 hours) the calf is again placed on the table and the vaccinated surface is thoroughly washed with soap and warm water, gently rubbed over by the clean hands of the operator. It is again washed with tap-water and finally cleansed with sterilised water. Next, any crusts that may have formed upon the vesicular lines and any epidermal debris are removed by the careful use of a sterilised india-rubber pad. Superfluous moisture is absorbed by sterilised gauze sponges. At this stage the site of each incision should present a line of continuous vesiculation. The skin having been put firmly on the stretch the vesicles and their contents are collected with a sterilised Volkmann's spoon, each line being treated in turn and scraped once only, care being taken that the edge of the spoon does not touch the neighbouring line of vesicles. In this way the vesicular pulp is removed without admixture of blood. The pulp obtained by the above procedure is received into a previously sterilised stoppered bottle of known weight. The abraded skin-surface of the

calf is gently washed with warm water and dusted over with starch powder or boric acid powder. The animal is then removed from the table and is weighed. Nearly all calves show a considerable gain in weight during their stay at the station and during the vaccination process. Each calf is then transferred to the slaughter-house attached to the Islington Cattle Market and is there slaughtered. A complete examination is made on behalf of the Board of the carcass and all the viscera by a veterinary surgeon especially appointed for the purpose. A report of this examination is received at the laboratories next morning. No lymph is used for any vaccination of the human subject until the animal in question is certified to have been healthy.

3. *Glycerination of the vaccine material.*—The bottle containing the lymph pulp from each calf is taken to the laboratories where the exact weight of the material is ascertained. The pulp is next transferred to a triturating machine, that employed being either one invented by Dr. Chalybäus of Dresden or a modified form of it. All the parts of the machine which come in contact with the lymph pulp are previously sterilised by prolonged steaming. The vaccine material, just as it is derived from the calf, is then passed through the machine, which is worked by an electric motor. When the pulp has been triturated in this way the amount of subdivision which it has undergone can be ascertained by suspending a loopful of the ground-up material in a watch-glass containing distilled water. If the trituration has been effectual such suspension should show only the minutest particles of pulp, causing the water to appear merely cloudy. The pulp is then passed through the machine a second time, together with six times its weight of a sterilised mixture of 50 per cent. of pure glycerine in distilled water. The resulting mixture is then once more passed through the machine, thus producing a fine and intimate emulsion. At this stage a loopful of the emulsion is withdrawn with a sterilised platinum needle and agar-agar plates are established in order to estimate both the number and the quality of the micro-organisms present in the lymph.

4. *Storage of the emulsion.*—The emulsion is next received into conical glass receptacles previously sterilised. By means of a stopcock at the apex of the cone the glycerinated lymph is run into small sterilised test-tubes capable of holding from four to 10 cubic centimetres. Each tube is filled as completely as possible, so that very little air remains in contact with the emulsion. It is plugged with a sterilised cork and sealed with melted paraffin which has been rendered aseptic with carbolic acid, and is then placed in a dark, cool cupboard or ice-chest. Week by week agar-agar plates are established from the emulsion with the result that the number of colonies is shown to diminish successively in the several plate cultures. At the end of a month the plates rarely show colonies of any sort.

5. *Use of the lymph at the Animal Vaccine Establishment prior to distribution.*—When the stage is reached at which agar plates show no growth after inoculation with the emulsion, samples of the lymph are drawn up into capillary tubes and despatched to the Animal Vaccine Establishment for the vaccination of children. The results of these vaccinations are recorded a week later, and from the number and size of the vesicles obtained an estimate is made as to the potency of the lymph.

6. *Transference of the glycerinated lymph to capillary tubes for distribution.*—When the lymph of a given calf has been shown to be satisfactory the bulk of it is transferred to sterilised capillary tubes by means of special tube-filling machines worked by water power. These tubes are next sealed in a small gas flame, every care being taken to prevent overheating of the lymph during the process. These sealed tubes are then stored in an ice-chest in boxes in such numbers that any quantity demanded up to some 6000 tubes per diem can be despatched at once to the National Vaccine Establishment at Whitehall, whence the lymph is distributed to public vaccinators.

7. *Recording the results of vaccinations by public vaccinators.*—Each public vaccinator receives in response to application made to the National Vaccine Establishment a consignment of lymph together with a schedule in which to record the results of its use, and these schedules, after having been examined at the National Vaccine Establishment, are sent to the laboratories. The schedules indicate the series number of the lymph, the date of its despatch from the National Vaccine Establishment, the name of the public vaccinator to whom it was supplied, the number of tubes sent, the dates when the several tubes were used, the

<sup>2</sup> Report of the Medical Officer to the Local Government Board, 1899.

number of persons vaccinated, the number of scarifications made, and the number of vesicles obtained. All these details are recorded at the laboratories, and from the last two items information as to the success which has resulted, both as regards individuals vaccinated and insertions of lymph made, is obtained and set forth, both in full and in the form of a percentage. In addition to these records a register is kept stating the particulars of the calves employed, the details of the lymph obtained from each calf, including the results of the bacteriological examinations, the results of the use of the lymph at the Animal Vaccine Establishment, and also the number of tubes of each series despatched to the National Vaccine Establishment.

During the first year of operations nearly 500,000 tubes of glycerinated lymph were sent out from the Government laboratories. Notwithstanding the difficulties that had naturally to be overcome in the inauguration of work of a character entirely new to practically all those engaged upon it, the success attending the use of the lymph at the hands of public vaccinators throughout the country was distinctly gratifying, the returns made by them to the National Vaccine Establishment showing that a case-success of 93 per cent. and an insertion-success of 83 per cent. had been attained. With a recent lymph series concerning which in the course of my work it became necessary to make special inquiry, and which had been distributed to 160 public vaccinators, the case-success and insertion-success were found to be 98 per cent. and 93 per cent. respectively. And at the present time it is by no means an unusual experience at the laboratories for returns showing complete case-success and insertion-success to be received.

Under the provisions of the Vaccination Act, 1898, which came into force in January, 1899, for a period of five years, and of the Vaccination Order (1898) of the Local Government Board, numerous changes in connexion with vaccination administration and with the performance of the operation were introduced in addition to the supersession of arm-to-arm vaccination by the use of glycerinated calf lymph. Thus whereas by the Vaccination Acts of 1867 and 1871 the parent or person having the custody of any child was required to procure its vaccination within three months of birth, this period by the Act of 1898 has been extended to six months. Again, no parent is now liable to a penalty under the compulsory clauses of the Vaccination Acts who affords proof that he has within four months of the birth of a child satisfied a stipendiary magistrate or two justices in petty sessions that he conscientiously believes that vaccination would be prejudicial to the health of the child. Moreover, in no case can proceedings now be taken more than twice against a defaulting parent—namely, once under Section 29 of the Act of 1867 and once under Section 31 of the same Act provided that the child had reached the age of four years. When first propounded the so-called "conscience clause" was received with a storm of opposition, more particularly on the part of the medical journals, but it is now, I think, generally admitted that the clause has justified its existence, since its operation has practically done away with "martyrdom" and so has weakened to no slight extent one of the principal weapons in the armoury of the anti-vaccinationists.

The operative procedure in public vaccinations was formerly based on the necessity of carrying on a weekly series of transferences of vaccine lymph from arm to arm, this method having been originally introduced as the best means then attainable of insuring the activity and comparative purity of the lymph. In large urban districts, therefore, vaccinations were performed week by week throughout the year, while in small towns and rural districts quarterly or half-yearly periods, each comprising several weeks, usually sufficed. In the latter cases material for starting the series was generally obtained by vaccinating one or more infants a week previously, and if fresh lymph for this purpose could not be obtained from a private case or through the good offices of a neighbouring practitioner a few doses of human or calf lymph stored in tubes or on points respectively were provided on application being made to the National Vaccine Establishment. Again, for the purposes of arm-to-arm vaccination the provision of stations, to which children were brought, first for the performance of the operation and again after a week's interval for inspection of the results, was an essential. The occasional hardships to the mothers and a somewhat remote possibility of danger to the children involved in being taken long journeys to a vaccination station in bad weather, or arising from the collecting together in one room of a number of children and adults, one or more of whom

might happen to be suffering at the time from some infectious disorder, are a few of the reasons which appeared to render a change in this regulation desirable; as a matter of fact, it would appear that nothing but good has arisen from the substitution of domiciliary for station vaccination, coupled, as it is, with the use of glycerinated calf lymph, "or such other lymph as may be issued by the Local Government Board." It may here be mentioned, however, since the fact appears to be comparatively unknown, that it is not essential for a public vaccinator to employ the lymph issued by the Government unless the parent or person in charge of the child exercises his right of insisting on its use. But the public vaccinator "must not employ lymph supplied by any person who does not keep an exact record of its source," and in any case he "must keep such record of the lymph he uses for vaccinating" as will enable him always to identify the origin of the lymph used in each operation. Further, the operator is enjoined never, when he has unsealed a tube of lymph, to attempt to keep any part of its contents for the purposes of vaccination on a future occasion. Moreover, he is required to use an artificial blower for the purpose of expelling the lymph instead of applying his mouth to the tube.

Two other sections of the "Instructions to Vaccinators under Contract" in the third schedule of the Vaccination Order of 1898 are of special importance. One of these refers to the aseptic precautions with which every stage of a vaccination should be carried out. "These should include (1) the cleansing of the surface of the skin before vaccination; (2) the use of sterilised instruments; and (3) the protection of the vaccinated surface against extraneous infection, both on the performance of the operation and on inspection of the results." The other section to which I would specially refer requires that whenever possible four separate, god-sized vesicles, or groups of vesicles, not less than half an inch from one another, must be produced, and that in any case the total area of vesiculation resulting from the vaccination should not be less than half a square inch. As regards the standard thus set up and insisted on in the case of those vaccinators whose work comes under periodical inspection at the hands of the Medical Inspectors of the Local Government Board, it may at once be admitted that there is no special magic in the particular number "four." But an area of half a square inch having been recognised in the report of the Royal Commission as probably the least extent of vesiculation absorption from which is capable of affording adequate protection to the individual against subsequent invasion by small-pox, the regulation requires that this area should be distributed over four insertions, mainly for the reason that experience has shown that less inflammatory reaction and less permanent destruction of skin tissue are likely to ensue than if the attempt be made to secure the same area by means of a less number of insertions of lymph.

This leads us to the consideration of what constitutes "efficient" vaccination. The answer may be summarised as follows: the clinical activity and bacteriological purity of the lymph employed for vaccination; the skilful performance of the operation itself; the making an adequate number of insertions of lymph over a sufficient area; the observance of precautions needful for ensuring strict asepsis, both at the time of vaccination and subsequently until the vaccination wounds are soundly healed,—all these are matters to be regarded as essential to "efficient vaccination." But, as has been well said by a writer in the *Edinburgh Review*, "even after efficient vaccination a slow progress away from safety and towards danger is inevitable and revaccination at least once after childhood is necessary if protection is to be maintained."

Much care has been exercised of late not only by the Government but also in many of the trade establishments, especially on the continent, in the preparation of the glycerinated calf lymph which in public and private work alike is now almost universally employed in this country. But this lymph, although under proper conditions usually capable of retaining its potency for many weeks or months, nevertheless under certain circumstances, at present imperfectly understood, is liable to become rapidly weakened and even eventually to become altogether inert. Possibly the condition of the calves from which the lymph is obtained, especially as regards their general health and the suppleness or the reverse of their skin, or exposure of the lymph to the action of light or to a high temperature are of special importance. Consequently in order to ensure the best results from its use it is not only

necessary that great care should be exercised in its manufacture, but it is also advisable that the lymph should be employed for vaccination as soon as possible after bacteriological examination has demonstrated its freedom from suppurative and other extraneous micro-organisms. We unfortunately at present possess no test of the efficiency of lymph other than the clinical one, and it is further of interest in this connexion that samples of lymph capable of affording fair results on the calf may fail to cause equal response when employed for vaccination of the human subject. It is therefore of importance that, as is invariably done in the case of the lymph issued from the Government laboratories, every batch should be tested on children before being distributed for general use.

As regards the carrying-out of the operation itself, it is somewhat unfortunate that there exists no official definition of what constitutes a "successful vaccination," and in consequence it is open to any practitioner to give a certificate of successful vaccination in cases where but one minute vesicle may have been produced. It is to be feared that such certificates are too frequently given, and it cannot be too strongly urged that vaccination of this sort involves incomplete protection. The standard laid down by the Local Government Board, to which reference has already been made, has for the most part proved easily attainable in practice, and it is much to be desired that in private as in public work the attainment of this standard should be aimed at in every instance. The suggestion has been made that in the form employed in certifying to the success of a vaccination the medical man performing the operation should be required to state the number of insertions of lymph made and the number of vesicles, or groups of vesicles, resulting therefrom. But it does not appear that the value of such a regulation would be very great in the absence of a further regulation requiring that all vaccinations, public and private alike, shall conform to a definite standard. The further suggestion has been made that every medical man should become a public vaccinator to the extent that he should have the right of claiming a fee from the public funds for every vaccination performed by him provided that he was willing that his work should be subject to inspection on behalf of the Government. But the originators of this idea can hardly have realised the magnitude of the inspectorial staff that would be required if such an arrangement were to be put in force.

The treatment of the arm at the time of vaccination and subsequently during the progress of the case is another subject which has aroused considerable controversy and concerning which much divergence of opinion would appear to exist. Thus in some quarters the initial cleansing of the arm is said to be objected to by the parents as a reflection on the care, or want of care, on their part as regards the condition of their children, but in general it is found that a little tactfulness in explaining the difference between ordinary and surgical cleanliness has sufficed to overcome the difficulty. In addition to this aspect of the case the friction employed in the process is of value in causing a slight capillary dilatation which undoubtedly contributes to the success of the operation. Water, soap-and-water, spirits of wine, or antiseptic solutions of greater or less potency containing boric or carbolic acids, lysol or perchloride of mercury, for instance, are employed by different operators for the purpose. Of these in all probability a warm solution of boric acid is the most generally useful, a stronger antiseptic such as corrosive sublimate, unless removed by the subsequent use of sterilised water or alcohol, being liable to exert a somewhat deleterious effect upon the lymph. The method to be employed at the operation and during the maturation of the vesicles for the protection of the vaccinated area from extraneous infection has not been defined by the regulations, for the reason that it appeared probable that each man would best attain the desired end by the same methods that he would ordinarily employ in the treatment of any other case of minor surgical injury. As was to be expected, therefore, the means adopted for the protection of the vaccination wounds have been very various and different trade firms have undoubtedly reaped an extensive harvest by the introduction and energetic advertisement of special dressings of one and another kind. In Paris, at the time of my official visit, a semi-transparent material known as "*taffetas Marinier*," not unlike thin isinglass plaster, and which adheres to the skin when moistened with water,

was, I found, invariably employed to protect the vaccinated area during the first few days following the operation, and a somewhat similar substance advertised by an English firm is, I believe, at present utilised to a considerable extent in this country. But during the second week of the process it is essential that some dressing of an absorbent nature should be employed, as it is during this period that oozing from the vesicles occasionally supervenes. The means employed for retaining the dressings in position are almost as numerous as the latter themselves. At the Government station in Lamb's Conduit-street a dressing composed of a couple of layers of boric lint, kept in place by means of pieces of rubber strapping which do not entirely encircle the arm, is applied at the time of vaccination and this is replaced by another exactly similar dressing when, a week later, the case returns for inspection of the result. But whatever be the nature of the dressing the free use beneath it of a dusting powder of boric acid has a most beneficial effect in preventing any undue amount of inflammatory reaction.

Concerning the nature of the instrument best adopted for the purpose of vaccination I desire to offer a few remarks. Here again each operator will probably attain the greatest measure of success with that instrument to the use of which he has been accustomed. But, speaking generally, the less complicated it is the better. Again, it is desirable that it should be formed entirely of steel so that it may be readily sterilised by boiling or by heating to redness in the flame of a spirit lamp, the first method being preferable as not tending to injure the temper of the metal. Possibly the best and certainly the simplest form of instrument is the ordinary triangular-headed surgical needle, which possesses the advantage that on account of its small cost a fresh one, if thought necessary, can be employed for every operation. It is curious to find, on turning to the old literature of small-pox inoculation, how all the processes of vaccination were originally copied from those which the inoculators had gradually elaborated. It was of course to these practitioners that Dr. Jenner was indebted for the model on which he framed his method of arm-to-arm vaccination, and in connexion with my choice of an instrument I was specially interested to find that Dr. Emanuel Timoni in a paper on the practice of inoculation among the Turks, presented to the Royal Society in 1716 by Dr. Woodward, makes the following statement: "These punctures ..... succeed best in the muscles of the arm. .... The needle is to be a three-edged surgeon's needle; it may likewise be performed with a lancet."

The manner of operating which affords the most generally successful results consists in blowing out the lymph from the capillary tube in which it is stored on to the surface of the skin at different points, the number and situation of which must correspond with those of the vesicles which it is desired to obtain. The skin, put slightly on the stretch, is then gently scarified, *through each droplet of lymph*, with the needle or other instrument, first in one direction and then in another, more or less at right angles to the first, the drawing of blood being avoided as far as possible. In this way the corium or superficial layer of the skin is thoroughly opened up and in some measure removed and thus the emulsion is brought into intimate relation with the cells of the true skin beneath. Operating in this fashion and employing lymph of normal potency, it is quite easy to obtain an area of vesiculation satisfying official requirements. Many operators, I find, reverse the procedure somewhat, first making their scarification and then rubbing on the lymph. But whether it be that some of the minute scratches are thus closed up as the lymph is applied, or whatever else the reason, certain it is that the results obtained are usually by no means comparable with those following on the method of scarification *through* the beads of lymph previously dropped upon the skin.

The operation having been completed, it is well to avoid too great haste in applying the protective dressing, especially if this be of the nature of an absorbent pad or if it be impregnated with some powerful germicide, as in the case of sal-alembroth wool. Some little time necessarily elapses before complete absorption of the vaccine emulsion and the exuded lymph has taken place, and to insure the best results a little exercise of patience is essential. With the object of hastening this period of drying I some time ago devised a method of removing the glycerine from the lymph emulsion after such time as bacteriological tests showed that it had fulfilled its purpose of destroying extraneous micro-organisms,

and replacing it with an equal amount of an inert fluid of similar specific gravity. But the more rapid drying of the vaccinated area thus obtained appeared hardly to compensate for the extra trouble involved in the special preparation of the lymph.

When every care has been taken to protect the arm during the progress of the vaccination and to prevent the premature detachment of the crusts the amount of permanent scarring of the skin which remains may be astonishingly slight. This is, I think, one of the results of modern methods of vaccination to which as yet attention has hardly been sufficiently directed, although in the future it is likely to prove a matter of considerable importance. There can be little doubt but that the huge and deep scars which not infrequently resulted from the vaccinations of former years were due to some extent to excessive destruction of skin tissue by micro-organisms other than that specific to vaccinia. If this be so, then it becomes apparent that persistence of such large and deep scars, practically throughout life, does not necessarily afford evidence that any equivalent degree of immunity against the infection of small-pox is enjoyed by their possessor. To this fact attention has been called in a recent communication to the *British Medical Journal*, although the writer propounds a somewhat different interpretation of the facts which he has observed.

The question naturally arises as to whether appreciable advantage to the community can be proved to have resulted from the adoption of our more modern methods of vaccination. It is for several reasons somewhat difficult to give as yet any very definite answer, although such statistics as are at present available are decidedly encouraging. There can be no doubt that the operation of the most recent Vaccination Act has been accompanied by a very considerable increase in the number of vaccinations performed, although it should be borne in mind that this increase is, in some degree at any rate, to be accounted for by the vaccination of cases previously in default, a source from which it is unlikely that the figures can be continuously augmented. None the less, however, it is matter for satisfaction that the vaccination of these outstanding cases should have been secured. From a return presented to the House of Commons on August 6th, 1900, which is the latest available source of information, we learn that in the year 1899, the first during which the Act of 1898 was in force, the number of certificates of successful primary vaccinations received showed an increase of 169,035, or no less than 33.8 per cent. over the figures for the previous year, the totals for the two years being 500,314 in 1898 and 669,349 in 1899, respectively.

But there is another source from which we may learn something as to the value of modern methods of vaccination. I refer to the annual reports of the Registrar-General under the heading, "Deaths attributed to Cow-pox and other Effects of Vaccination." For a series of years deaths thus registered averaged one every week for the whole of England and Wales, but whereas in 1889 and 1892 the actual number of deaths included under this heading was 58 and in 1893 it was 59, in 1900 the figures had sunk to 25. For England and Wales the statistics for the first three-quarters of the present year are not as yet available, but, thanks to the courtesy of Dr. J. F. W. Tatham, I am able to state that in London during that period only two deaths occurred in which vaccination was referred to in the certificate. In this connexion also it may be mentioned that at the last dinner of the Public Vaccinators' Association Dr. G. Danford Thomas was able to state that, contrary to his experience in former years, he had not had occasion in the course of his duties as coroner to hold an inquiry into a single case in which death was alleged to have been in any way due to vaccination since the date on which the Act of 1898 came into operation.

A couple of years hence the whole question of vaccination must again occupy the attention of the Legislature, by which time we may perhaps hope to have made further advance both in our methods and in the results obtained therefrom. For there is no finality in scientific work, and if in connexion with the subject under consideration much has already been accomplished in the past there are still undoubtedly many points awaiting elucidation in the future.

In conclusion, I desire briefly to call attention to a matter which has always aroused keen controversy and which just now must needs be of special interest—the question, namely, as to the relationship of vaccinia to small-pox. For, not unfrequently, the difficulty experienced by myself and many other investigators in attempts to transmit human small-pox

to bovines, whether cows or calves, has been cited as a reason for regarding with distrust the theory first expounded by Dr. Jenner, that cow-pox, whether carried through the horse as intermediary host or not, was originally derived from small-pox in the human being. But a great deal, at any rate, of the small-pox which was prevalent during the time that Dr. Jenner lived and wrote was of that comparatively mild variety which, under the name of "inoculated small-pox," was intentionally produced in healthy subjects, with the object of thereby conferring protection against subsequent attack by the disease in virulent form. So mild, indeed, at times were the results of inoculations in the hands of such operators as Adams and the brothers Sutton that no obvious effect was observed, with the exception of the local vesicle arising at the site of insertion of the small-pox virus, and the patients suffered but little inconvenience. Many of them doubtless, therefore, would be capable of following their ordinary avocations, which would hardly be possible in the case of persons contracting small-pox in the ordinary way, among whom the disease was apt to exhibit such virulence as to account for the death of perhaps 50 per cent. of those attacked.

Not only were the effects following on inoculation comparatively mild, but the disease in this form was intentionally brought into many country districts which otherwise might not have become invaded. In the light of these facts, it has for some years past been borne in upon my mind more and more convincingly that it was not improbably from the inoculated form of small-pox, rather than the ordinary variety, that much of the cow-pox in the pre-vaccination era was derived. It is not difficult to understand how that the cracks so often found on the udders of a cow might become infected by a milker with fingers contaminated by contact with the inoculated sore upon his arm.

I determined, therefore, if possible to put the matter to the test, and learning that in Nubia and in certain parts of India the inoculation of small-pox is still carried out, I made numerous endeavours to obtain the necessary material, but unfortunately, up to the present, without success.

In default of inoculated small-pox in the human subject I made trial of the monkey, which my previous work had shown to be readily susceptible to the disease, the various phases of which in this animal closely resemble those observed in man. The experiments were commenced in 1898 and the small-pox material has been obtained from cases coming under observation during outbreaks of this disease at Middlesbrough, Glasgow, and London. In each of three separate series of experiments the human small-pox lymph or pulp was first inoculated directly on calves and, in every instance, so far as could be observed, with altogether negative results. But with monkeys success was as invariably obtained, and when, after one or more passages through this animal, the contents of the local inoculation vesicles were employed for insertion on the calf, an effect was now produced which, after one or more removes in that animal, was indistinguishable from typical vaccinia. Moreover, from the contents of vesicles raised in this manner on the calf a considerable number of children have in turn been vaccinated, and afterwards kept under observation for about a couple of months. Every such vaccination "took" normally and in no case was any bad result subsequently observed by myself or by the parents of the children, no "generalisation" of the eruption occurring in any instance. (A series of photographs of monkeys, calves, and children was shown on the screen.)

The point of interest in these experiments is found in the fact that whereas the human small-pox material employed could not be got to "take" directly on the calf, nevertheless results typical of ordinary vaccination were obtained when the strain of lymph, after inoculation with it of a series of monkeys, was again transferred from the inoculation vesicles on this animal to the epidermis of the calf. Interesting corroboration of my results has recently come to my knowledge in which the use, on calves, of lymph from the vesicles of cases of human inoculated small-pox has afforded opportunity, in Burmah, of originating, on several different occasions, strains of excellent vaccine lymph.

Earl's Court-square, S.W.

**LUUACY IN DEVONSHIRE.**—At the meeting of the Exeter Corporation Asylum Committee held on Dec. 11th it was decided that draft plans for additional accommodation for 50 patients should be presented to the Commissioners in Lunacy for approval.

OBSERVATIONS ON THE ETIOLOGY AND MORBID ANATOMY OF TUBERCULOUS MENINGITIS.<sup>1</sup>

By EDMUND CAUTLEY, M.D. CANTAB., &C.,  
PHYSICIAN TO THE BELGRAVE HOSPITAL FOR CHILDREN; ASSISTANT  
PHYSICIAN TO THE METROPOLITAN HOSPITAL.

FOR the data of this paper I have taken the records of the last 27 cases of tuberculous meningitis which have been under my care during life and have been subsequently examined in the dead house (vide Table). Though the number is too small to justify dogmatic statements on any one point, the results obtained from the inquiry are sufficiently definite to enable me to bring before you certain deductions as to the etiology of the disease.

1. *The age distribution.*—The following table shows the age distribution:—

Age in years.	Males.	Females.	Total.
0 to 1 ... ..	0	3	3
1 „ 2 ... ..	5	1	6
2 „ 3 ... ..	2	3	5
3 „ 4 ... ..	1	3	4
4 „ 5 ... ..	2	2	4
5 „ 10 ... ..	4	1	5
—	14	13	27

No less than 22 out of the 27 cases occurred during the first five years of life and only five during the second five years. This result confirms those of other observers that the disease is most common under five years of age. Some writers state that it is rare during the first year and give statistics in support of their statements. Others find it frequent during the first year. It is not always clear, from the figures quoted, whether the statements are based on cases diagnosed during life or only on those which have been verified after death. If the figures are based on clinical records only it is probable that the frequency of the disease during the first year would be over-estimated, on account of the difficulty in invariably making an accurate diagnosis between the simple posterior basal meningitis, which is unduly prevalent during the first year of life, and true tuberculous meningitis. My own figures show that the distribution of the cases during these first five years is fairly equal for the different years. There is no preponderance of either sex—14 males to 13 females.

2. *The influence of heredity.*—In recent years it has become customary to ascribe very little importance to heredity in the production of tuberculous affections, except in so far as the sufferers are exposed to direct infection from association with a tuberculous relative, or may inherit a peculiarity of constitution which renders them susceptible to such infection. It is well known how difficult it is in hospital practice to obtain accurate family histories and that all statements as to the occurrence of “consumption” in the parents or other relatives must be viewed with suspicion. The results obtained on this point are opposed to the theory of heredity but must not be too strongly insisted upon. In 22 of the cases it was definitely stated in the notes that there was no history of phthisis in the parents or other children. Of the remaining five cases a few facts may be given. In only one case was the mother stated to be affected.

CASE 14.—The patient was a female, aged 6 months. The mother was said to be very ill with “consumption and bringing up blood.” The child was only nursed for one week and was then brought up on condensed milk. She had been taken out of doors very little. She died with symptoms of tuberculous meningitis, and there were found, in addition, tuberculous consolidation of the upper lobe of the left lung, a cavity in the upper lobe of the right lung, general dissemination throughout the lungs, and a few tubercles in

the spleen. No note was made as to the condition of the mediastinal or mesenteric glands.

No better instance could be given of probably direct infection from the mother through the respiratory tract. The next four cases also illustrate the possibility of direct infection from a parent.

CASE 2.—The patient was a female, three years and nine months old, who died after an illness of 19 days' duration. Tubercles were found in the meninges, liver, and spleen. No caseous glands were found. The cribriform plate of the ethmoid was carious. While the child was ill the father was an in-patient at the Brompton Hospital for Consumption.

The case suggests strongly that infection took place through the nose. To quote Osler: “In those instances in which no primary focus has been discovered it has been suggested that the bacilli reach the meninges through the cribriform plate of the ethmoid from the upper part of the nostrils, but this is not probable.” It is certainly not probable that the meninges can be infected by this route unless disease of the bone is first set up. The possibility of direct infection is present in the next case, which also presents another point of interest, to be subsequently discussed—namely, the influence of injury in the production of the attack.

CASE 1.—The patient was a female, aged two years and six months, who died after an illness of 17 days' duration. After death there were found basal meningitis, with only a few tubercles in the meninges, and no evidence of a tuberculous focus. A few pleural adhesions were present at the apex of the right lung. The child had a fall three weeks before the onset of the symptoms. The father was said to be “consumptive” and a sister was at the time in the Brompton Hospital for the same disease. It is a question whether the tubercles in the meninges were the primary cause or secondary to a basal meningitis set up by the fall.

The other two cases presented interesting features. In both the father was said to be “consumptive.”

CASE 19.—The patient was a male, aged two years, who died after an illness of 18 days' duration. A large cavity was found in the lower lobe of the left lung; there were general dissemination throughout the lungs and caseous mediastinal glands.

CASE 24.—The patient was a male, aged three years and seven months, who developed left hemiplegia during the course of the illness. An old tuberculous mass was found in the right external capsule and tuberculous nodules in the cerebellum. The lungs were stuffed with tubercles and the mediastinal glands were caseous. Only one tubercle was present in the spleen.

These five cases were the only ones in which a family history of tuberculous disease was obtained and they all illustrate the probability of direct infection.

3. *Injury as an etiological factor.*—In only one instance (Case 1), that already referred to, could injury be invoked as the exciting cause of the disease. Even in this case it is possible that the meninges had become infected before the injury, for the presence of pleuritic adhesions at the right apex suggests former tuberculous mischief. All text-books recognise the importance of this point. It is more specially applicable in the case of children who go to school. For some reason or other the child receives a box on the ear, or a rap on the head by the knuckles or ruler or other punitive instrument in the hands of the teacher. Subsequently the child dies from tuberculous meningitis which is ascribed by the parents to the injury. Possibly the unfortunate teacher is hauled before a coroner's court and severely censured by a typical British jury. The common and usually accepted explanation is that the child was punished for the stupidity or inattention, the state of mind so likely to be present during the early stages of the disease. It is therefore imperative in such cases that a careful post-mortem examination should be made in order to ascertain whether there is a tuberculous focus present which might have given rise to the meningeal infection. On the other hand, a case like the one quoted might be brought forward as an argument in favour of injury being the exciting cause. Injury to the brain or meninges might cause local congestion or damage of such a nature as to render the affected part a suitable soil for the growth of the tubercle bacillus, which without such advantageous conditions might have perished. This is the only instance out of the 27 cases which is favourable to this view.

4. *The channel of entrance of the bacillus into the system.*—In view of the recent discussions and observations on the

<sup>1</sup> A paper read before the Society for the Study of Disease in Children on Nov. 15th, 1901.

TABLE GIVING DETAILS OF NECROPSIES IN 27 CASES OF TUBERCULOUS MENINGITIS.

No.	Sex.	Age.	Pleura.	Lungs.	Glands.		Other lesions.
					Mediastinal.	Mesenteric.	
1	F.	2½ years.	A few adhesions at the right apex.	No tubercle.	Normal.	Normal.	A few tubercles at the base of the brain. No other evidence of tuberculosis.
2	F.	3½ years.	—	"	"	"	Tubercles at the base of the brain. Caries of the cribriform plate of the ethmoid.
3	M.	13 months.	—	"	Caseous.	"	—
4	F.	3½ years.	—	"	"	Caseous.	Peritoneal surface of the diaphragm covered with miliary tubercles.
5	M.	4½ years.	—	"	"	Normal.	—
6	M.	9 years.	Old adhesions of the left lower lobe.	"	"	"	—
7	F.	2 years.	Recent adhesions on the right side.	Scattered miliary tubercles in two upper lobes of the right lung.	"	"	Broncho-pneumonia of the left lower lobe.
8	F.	4½ years.	A few tubercles on the right pleura.	A few tubercles in the lower lobe of the right lung.	"	"	—
9	F.	1½ years.	A few tubercles on both parietal pleura.	General dissemination.	"	Large.	A few tubercles on the parietal layer of the pericardium.
10	F.	4½ years.	Tubercles scattered over both pleura.	"	"	Normal.	—
11	M.	4½ years.	Old adhesions at the right apex.	Stuffed with rather advanced miliary tubercles.	"	"	Liver and spleen large; tubercles in both. Perisplenitis.
12	M.	5 years.	—	General dissemination.	"	"	—
13	F.	8 years.	—	Slight general dissemination.	Very extensively caseous.	"	Acute endocarditis.
14	F.	6 months.	—	Tuberculous consolidation of the left upper lobe. Cavity in the right upper lobe. General dissemination.	Not noted.	Not noted.	—
15	F.	6 months.	—	Caseous patches in the right middle and lower lobes. General dissemination.	Caseous.	Normal.	—
16	F.	11 months.	—	Caseous mass and cavity formation in the right lower lobe.	"	"	—
17	M.	1½ years.	Right lower lobe universally adherent.	Extensive caseation of the right lower lobe.	"	"	Liver large
18	M.	1½ years.	Pleuritic adhesions at the right base.	Caseous mass at the base of the right lower lobe.	Not noted.	Not noted.	—
19	M.	2 years.	Pleuritic adhesions.	Cavity in the left lower lobe and tubercles in the rest of the lung. A few in the right lung.	Extensively caseous.	Normal.	—
20	F.	2 years and 10 months.	Recent adhesions of the right upper lobe.	Caseous patch in the right upper lobe, beginning to break down.	Caseous.	Large.	—
21	F.	3 years.	Patch of tubercles on the right parietal pleura and adhesion to diaphragm.	Extensive tuberculous broncho-pneumonia.	"	"	Tuberculous cholangitis; perihepatitis; perisplenitis.
22	M.	6 years.	—	Old fibroid change; recent tubercles and caseous masses in the right upper lobe. Caseation of both lower lobes extending from glands.	Very extensively caseous.	Normal.	—
23	M.	7 years.	—	Caseating right upper lobe due to rupture of a caseous gland into it.	Caseous.	"	—
24	M.	3 years and 7 months.	—	General dissemination.	"	"	Tuberculous mass of old standing in the right external capsule. Tuberculous nodules in the cerebellum.
25	M.	13 months.	—	General dissemination, especially at the right apex.	"	Caseous.	Tuberculous subcutaneous nodules. Four caseating nodules in the brain.
26	M.	1 year and 5 months.	—	General dissemination. Small vomica in the right upper and left lower lobes.	"	"	Tuberculous ulcers (two) in the small intestine. Perisplenitis.
27	M.	2 years.	—	Caseating and calcifying nodule in the right middle lobe.	"	Extensively caseous.	Intestines not examined.

relationship of the bacillus of bovine tuberculosis to that of the human disease, and on the infectivity of the milk of tuberculous cows, this point is one of extreme importance. In the last edition of Fagge's Text-book of Medicine (vol. i., 1901), edited by Pye-Smith, it is stated in the chapter on Tuberculous Meningitis that "the exciting cause is the entrance of Koch's bacillus into the circulation, and in children this is probably by way of the intestinal tract from the milk of tuberculous cows." Kanthack, Delépine, and others have proved that the bovine tubercle bacillus is frequently present in cow's milk. It has been found by Bang, Bollinger, and others in the milk of cows affected with general tuberculosis or tuberculous disease of the udder. It has been experimentally determined by Hirschberger that the milk of tuberculous cows may be infective, even though the udder is unaffected. Kempner and Rabinowitsch in 1899 found the bacillus in the milk of cows which reacted to tuberculin but gave no other evidence of tuberculosis, and their results have been confirmed by Ostertag, Adami, and Martin. There is, in fact, no shadow of doubt that the bovine tubercle bacillus is often present in cow's milk. One warning must be given on this point. Acid-resisting bacilli similar in nature and appearance to the tubercle bacillus have been also found in milk (Petri, Beck, Santoni, Rabinowitsch, &c.), in the udder (Ludwig Neufeld), in the intestines of healthy and tuberculous cows (Olt), in the timothy grass sometimes used for fodder (Möller), and in the dung (Severin). These bacilli cannot be distinguished microscopically but can be readily distinguished by intra-peritoneal injection into guinea-pigs. Tuberculosis can be produced in calves and pigs by feeding them on tuberculous milk, and by analogy it has been assumed that a similar result will arise in children. In support of this the reports of the Registrar-General are often quoted. In these reports it appears that the disease called "tabes mesenterica," usually regarded as a tuberculous affection, is increasingly prevalent among infants. With regard to this latter statement I wish to enter a very strong protest. Tabes mesenterica is very rare among infants, and there is little doubt that almost all the cases so entered in mortality statistics as occurring in infants under one year of age are neither more nor less than the interesting disease known to the public by that blessed name "consumptive bowels"—that is, diarrhoea and wasting due to improper feeding and ending in death. I have never yet seen a true case of tabes mesenterica in an infant examined post mortem, although I have been constantly on the watch for one, and I am strongly convinced that it would conduce to scientific accuracy if the name were eliminated from our nosology.

To return to the point under consideration. The main channels of infection are the respiratory and the alimentary tracts. Of quite secondary importance are the ear and skin, both of which occasionally prove channels of infection. Let us consider, then, what evidence these post-mortem records yield in favour of one or other of these modes of entry of the bacillus. Using the term "mediastinal glands" to include all the glands in the anterior and posterior mediastinum, at the bifurcation of the trachea, and at the roots of the lungs, a most striking fact is at once revealed. In only two instances were these glands normal and in these the tuberculous process was limited to the base of the brain, being in one of them associated with caries of the cribriform plate of the ethmoid, and in the other possibly secondary to a localised pleurisy at the apex. In two other instances (Cases 14 and 18) no note was recorded as to the condition of these glands, but I have little doubt that, considering the advanced tuberculous disease in the lungs, the glands must almost certainly have been affected. In the remaining 23 cases one or more of the mediastinal glands was caseous. The one most often affected, frequently the only one, was the gland situated at the bifurcation of the trachea, commonly called the pretracheal gland. In four of these 23 cases the mesenteric glands were also caseous. In one of these four (Case 4) the peritoneal surface of the diaphragm was covered with miliary tubercles and there were tubercles in the spleen, while the lungs only showed evidence of bronchitis. The other three cases, in which both sets of glands were caseous, are of much interest.

CASE 25.—The patient was a male, 13 months old, who was under my care for two months for subcutaneous tuberculous nodules. There were four such nodules, varying in size from a split pea to a horse-bean, one of which was said to have been in existence since the age of four or five

months. He developed meningitis from which he died. In addition to tuberculous basal meningitis the brain was found to contain caseating nodules, the lungs showed general dissemination, especially at the right apex, and there was extensive caseation of the mediastinal and mesenteric glands, with a few tubercles in the spleen.

In the other two (Cases 26 and 27) there was evidence to warrant the assumption that the abdominal tuberculosis was secondary to the swallowing of tuberculous material coughed up from the lungs. Thus, in a boy, aged 17 months, tuberculous vomicae were found in both lungs and two small tuberculous ulcers in the small intestines. In a boy, aged two years, an old caseating and calcifying nodule was found in the lung, but unfortunately the intestines were not examined. In nine instances there was more or less dissemination in the lungs, or in the lungs and pleura, but no evidence of old-standing disease. In only one of the nine, the child with subcutaneous nodules, were the mesenteric glands caseous. In 12 instances the lungs showed extensive tuberculous disease of old standing—namely, caseation and in some cases excavation.

Looking at the facts from another point of view it seems somewhat remarkable that, if the alimentary canal is so liable to tuberculous infection as the upholders of the theory of infection by tuberculous milk would have us believe, in only two out of these 12 cases in which the disease was advanced and of old standing in the lungs was there evidence of infection of the mesenteric glands. In two the state of these glands was not noted. Of course, it is clear that such infection may have been present and that microscopical or experimental evidence might have proved some of these glands infected; but even if this were so, the facts strongly confirm the view that the respiratory tract was the primary source of infection. It is also clear that the alimentary tract is not markedly susceptible to infection by the human tubercle bacillus.

It has been stated that the tubercle bacillus of cattle is not dangerous to human beings. Even if we only accept the statement in a modified form and say that the bovine bacillus is not nearly as infective as the human bacillus, our post-mortem facts afford a still stronger proof of the insusceptibility of the alimentary tract to infection by the bovine bacillus, seeing that it so often escapes although exposed to the risk of infection by the human bacillus in chronic tuberculous disease of the lungs. In young children, as is well known, sputum is swallowed and not expectorated. Consequently the liability to secondary infection of the alimentary canal is enormous, whereas the post-mortem evidence proves it to be infrequent. In six instances was there no evidence of tuberculous disease of the lungs and yet in four of these the mediastinal glands were caseous. In one of the four the mesenteric glands were also caseous. It is possible that in these cases a small tuberculous lesion may have healed and left no trace visible to the naked eye or that the bacillus reached the gland through some other channel. In some instances in which the lung was affected the question arose whether the lung mischief was primary or secondary to an extension from the glands. In one case it was clear that the main part of the lung disease was due to the actual rupture of a breaking-down gland into its substance (Case 23). In some others the tuberculous process could be seen extending backwards from the glands along the lymph channels in a radiating fashion into the lungs. The probable sequence of events in most cases is that the bacillus is carried by the blood or lymph stream to a congested gland and there develops, finally causing caseation. Such a caseous gland may remain quiescent, may become calcified, may break down, may ulcerate through into the trachea or oesophagus, or may rupture into the lung or pleural cavity. In any case if it breaks down the infective material may become widely disseminated and cause a general infection. The post-mortem evidence may be summed up shortly as proving that the respiratory tract is the great channel of infection. It therefore follows that the danger from swallowing tuberculous cows' milk has been much exaggerated.

It is sometimes asserted that the bacillus can get into the system through the alimentary canal without producing a local lesion. Caseous mesenteric glands are found although the mucous membrane of the intestines appears normal. If the bacillus does not pass out of the intestines through the lymph channels to the glands it might possibly pass into the blood stream. Practically all the blood from the intestines goes through the liver. We should expect, then, that if the bacillus passed into the blood stream it

would produce tuberculous disease of the liver. Miliary tubercles are indeed found in the liver, more often in the spleen, and less often in the kidneys, but only when there is considerable general dissemination throughout the body. It is rare to find old tuberculous foci in the liver and in none of these cases was such a focus found. There is no evidence at all strongly in favour of infection of the blood stream through the intestinal tract.

5. *Evidence derived from the diet of the patients.*—In eight out of 13 infants under three years of age the child was brought up on the breast for the greater part or all of the first year of life. In four the mode of feeding was not stated. In one the child was brought up on condensed milk, for the mother was too ill from tuberculous disease of the lungs to nurse it. These facts, as far as they go, are suggestive that cow's milk is not a very virulent source of infection, for a very large number of infants are brought up on cow's milk. During the last 10 years I have brought up a large number of infants on cow's milk, and as far as I know not one of them has subsequently come under my care for tuberculous meningitis. The milk has been boiled if the mothers have carried out the directions given.

6. *The state of the brain as indicative of the prospect of operative treatment proving beneficial.*—In about one-third of the cases there was no excess of fluid in the ventricles. In the remainder the fluid varied from a slight excess to a large amount. In many instances the cerebral tissues were very soft and occasionally almost diffident. Operative treatment can only be indicated as a means of relieving pressure and under the assumption that the child is dying from the coma induced by pressure. Such is not always the case, for many children died comatose in whom there was no evidence of increased intracranial pressure after death. The coma is probably due to the softening of the brain which may be associated with excess of fluid in the ventricles or may occur quite independently. Hence it is clear on anatomical grounds that operative treatment would only relieve pressure in about one-third of the cases, and that even in these cases it would do little or no good on account of the softening so often present and which is dependent upon insufficient blood-supply rather than on an excess of fluid. Moreover, these records indicate how very rarely the disease is limited to the brain and that the operation would only afford temporary alleviation of symptoms.

7. *Classification.*—It is possible to divide the cases on anatomical grounds into three groups: (1) simple tuberculous meningitis, in which the disease is limited to the brain (very rare); (2) tuberculous meningitis, secondary to a localised tuberculosis with little dissemination (the child dies from the meningitis); and (3) general miliary tuberculosis—cases in which the meningeal symptoms bear a comparatively unimportant relationship to the disease.

To conclude, I am strongly convinced that inheritance means exposure to infection of a weakly or predisposed child; that injury is very rarely an exciting or predisposing cause; that the respiratory tract is the great channel of infection; that the alimentary tract is rarely primarily infected; that cow's milk is very rarely, if ever, the source of infection; that limitation of the tuberculous process to the meninges is very rare; that the prognosis is very hopeless on account of the extent of the tuberculous disease elsewhere; and that operative treatment may be discarded as experimental rather than useful.

## OVARIOTOMY IN PREGNANCY: THREE RECENT CASES.

By JOHN B. HELLIER, M.D. LOND.,

HONORARY OBSTETRIC PHYSICIAN TO THE LEEDS GENERAL INFIRMARY AND LECTURER ON DISEASES OF WOMEN AND CHILDREN IN THE YORKSHIRE COLLEGE, VICTORIA UNIVERSITY.

CASE 1. *Ovariectomy at the third month of pregnancy; full term delivery.*—A married woman, aged 32 years, was admitted into the Leeds General Infirmary on Nov. 29th, 1900, for ovarian tumour. She complained that the abdomen had remained large since her last confinement, two years previously, and had steadily increased in size. She had missed two periods. The abdomen was distended by a large ovarian cyst reaching to within three fingers' breadth of the sternum; the umbilical girth was 35½ inches. Fluctuation

and thrill were very perceptible. On vaginal examination the uterus was felt lying anteverted, with a bulky fundus felt through the anterior vaginal wall. The cervix was soft; there were vulval and mammary signs of pregnancy. Ovariectomy was performed on Dec. 1st. The cyst, which contained 164 ounces, was large, multilocular, and non-adherent; the pedicle was from the left side. The right ovary, which was enlarged but not cystic, was not removed. The uterus was about three months pregnant and felt like a flaccid cyst. The wound healed by first intention and the patient made a good recovery with no threatening of abortion. She went to full term and bore a living child.

CASE 2. *Ovariectomy at the fourth month of pregnancy; full-term delivery.*—A married woman, aged 34 years, was sent to me by Mr. W. F. Chrispin of Castleford. Her last confinement was in July, 1900; menstruation returned in September and ceased again at Christmas. She had noticed an increase in the size of the abdomen about Jan. 1st, 1901. She was admitted into the Leeds General Infirmary on March 4th. She said that she had been married 15 years, had had 13 pregnancies and no miscarriages, but only one of her children had lived for more than 13 months. Her own health and general condition were good. The abdomen contained a uterus four months pregnant and a mobile tumour in the umbilical region which seemed to be loosely connected with the uterus. The tumour was rather solid on palpation. The usual signs of pregnancy were present. Ovariectomy was performed on March 9th and the tumour proved to be a semi-solid multilocular cystoma with the pedicle from the left of the uterus. There was extensive adhesion to the omentum and small bowel. The right ovary was normal. The uterus was four months pregnant. The operation was completed in the usual way; no drainage was employed. A continuous catgut suture was used for the peritoneum. The patient made a good recovery, except that there was some suppuration in the wound and the catgut came away entire and unabsorbed 11 days after. She had also a roseolous rash on the fifth and sixth day, which was followed by some desquamation. There was no threatening of abortion. She went to full term and bore a living child on Sept. 1st and made a good recovery.

CASE 3. *Ovariectomy for dermoid cyst in the sixth month of pregnancy; still-born child at the eighth month.*—This is a very interesting case. On May 13th, 1901, Mr. R. Smailes of Leeds asked me to see with him a patient, aged 42 years, who was five months pregnant and in whom he had discovered a post-uterine tumour. She had had three previous normal pregnancies and two miscarriages, the last being in the summer of 1899. After this she menstruated regularly till December, 1900, when she became pregnant. When two months pregnant she had some vaginal coloured discharge and the uterus was found to be retroflexed, and a pessary was applied. In April an examination was made to determine the position of the uterus, and the tumour was found in the pouch of Douglas. When I saw the patient she was a healthy woman in good condition and had no symptoms to suggest that pregnancy was abnormal. On vaginal examination an elastic cystic mobile tumour was found in the pouch of Douglas. It could be pushed up but soon returned. It seemed to be almost certainly ovarian and its removal was strongly advised, as it might cause serious complication in labour if it was left alone. Ovariectomy was performed in a nursing home on May 27th, Mr. Smailes administering chloroform, and Mr. C. H. Moorhouse assisting me. A median incision exposed the large flaccid uterus reaching to the umbilicus. The pedicle sprang from the right side; the oviduct was so greatly enlarged that it had to be examined carefully to make sure that it was not small intestine which it resembled. As traction on the pedicle did not easily withdraw the cyst the hand was introduced around the flaccid uterus and the cyst was extracted entire. The pedicle was twisted, the tumour was deeply congested, and there was free ascitic fluid. The left ovary was normal. The operation was concluded in the usual manner, with a continuous catgut suture through the peritoneum and interrupted silk-worm gut through the skin and muscle. The tumour was a dermoid cyst containing hair and sebaceous material and of about the size of an orange. During the first 24 hours after the operation the patient had more severe abdominal pain than I ever had observed after a successful abdominal section. She described the pain as agonising. There were no other bad symptoms and morphia administered hypodermically relieved the pain. She made an excellent recovery. The wound healed by first intention and she went home on an

ambulance at the end of three weeks and rested a week in bed. She got up and felt well, but said that she thought the child was dead. The abdomen did not increase and the breasts were flaccid. On August 5th she was delivered of a stillborn male fetus about eight inches long and very slightly macerated. The uterine surface of the placenta showed calcareous degeneration. She made a good recovery.

In Case 1 the enlargement of the right ovary might well be caused by that physiological enlargement of an ovary which is due to the presence of the corpus luteum of pregnancy. This condition ought to be borne in mind lest the mistake should be made of removing such an ovary. In Case 3 the operation for a small ovarian tumour concealed behind a large pregnant uterus is unusual. It was fortunate that the cyst was discovered. Its removal was easy, but if there had been adhesions in the pelvis the operation might have been difficult. It might have been necessary to extend the incision and to draw forward the womb. The child seems not to have survived the time of the operation. The cause of death is obscure, the operation was short, there were no symptoms of sepsis afterwards, and practically no pyrexia. The very severe pain and the morphia injected for it may have had something to do with the result. It is important to note that vaginal tapping would have been of no avail to lessen the cyst at the time of labour, the contents being caseous.

Ovariectomy is now recognised as the best treatment for almost all cases of pregnancy complicated by ovarian tumour, and the earlier it is done the better. It is best for the mother and best for the child (I do not here discuss the treatment of ovarian cyst at the full term and during labour). To leave the case untreated involves a risk of torsion of the pedicle amounting to 9 per cent., and also a risk of damage to the tumour in labour, especially in such a case as No. 3, and as pregnancy advances the ovarian pedicle is apt to become shortened by absorption of the broad ligament and hence the operation is less simple. The mortality of the expectant method was found by Remy to be 23 per cent. for the mother and 39 per cent. for the child.<sup>1</sup> The mortality in cases in which pregnancy has been terminated for the presence of ovarian tumour was 22 per cent. in 135 cases collected by Dsirne.<sup>2</sup> On the other hand, the mortality of ovariectomy in pregnancy performed with modern precautions is estimated at 5.9 per cent. by Dsirne, 8.4 per cent. by V. Weiss, and 4.09 per cent. by Vinay.<sup>3</sup> About one-fifth of the cases abort. The best results for the child are obtained between the third and fourth month. Even double ovariectomy has yielded good results for the child. In 17 cases there were only two abortions and three premature labours.<sup>4</sup>

LESLIE.

## A CASE OF EPIDEMIC DIARRHOEA IN AN INFANT TREATED BY IRRIGATION OF THE BOWEL.

By WILLIAM B. BENNETT, M.R.C.S. ENG.,  
L.R.C.P. LOND.

CASES of epidemic diarrhoea in infants during the past months have as usual been very numerous and very fatal. In his report on the health of the City of Liverpool during 1900, the medical officer of health (Dr. E. W. Hope) informs us: "As is always the case, the mortality from diarrhoea chiefly affected infants, nearly three-fourths of the total number of deaths being those of infants under 12 months old. It commenced to increase about the end of June and continued until October. 900 deaths were registered during this brief period, and to these must be added deaths from the closely allied or identical disease, English cholera."

The usual remedies for this deadly disease are very numerous and generally very useless. Having had many cases of epidemic diarrhoea under my care during last summer I have usually adopted the recognised forms of treatment. The diet, of course, in all cases is of the first importance, and here it is a matter of experience

that all milk and food containing milk should be cut off at once, white of egg and water, or barley-water alone, being the best diet for a few days. This alone in early simple cases is often sufficient, the vomiting particularly being very quickly arrested. A full dose of castor oil as early as possible is also excellent if it can be retained. The majority of cases, however, do not come under notice until the infant has been ill for some days, and even in early cases the above treatment is often quite insufficient, the diarrhoea and pain persisting. The drugs used are numerous, but many of them, particularly powders, are immediately vomited and so are useless. Grey powder, or some antiseptic such as the solution of perchloride of mercury, is very popular and useful, but the infant becomes so emaciated and weak in a very short time that some more immediate remedy is needed. The usual astringents are often of no avail, only acting as emetics, and then recourse is had to opium in minute doses, which is frequently necessary owing to the intense pain. So many of these cases after the most careful treatment end in convulsions, emaciation, and death that one is driven to the conclusion that these routine remedies are really of very little use, as is well shown in the following case, an account of which should prove of some interest since the child was cured in an unusual, but very simple, manner.

An infant, aged seven months, was taken ill with vomiting and diarrhoea on August 3rd, 1901. The mother gave him a dose of castor oil but no improvement taking place she brought him to me on the evening of the 4th. The child was then vomiting, being continually purged and in great pain, drawing up his legs on to the abdomen. I stopped all milk and other food and put him on barley-water only. This at once relieved the vomiting but the diarrhoea persisting I gave him on the 5th one and a half drachms of castor oil besides small doses of the solution of perchloride of mercury every three hours. No improvement taking place and the abdominal pain being exceedingly severe on the 6th I added to the perchloride one-minim doses of tincture of opium. This gave some relief to the pain and at first diminished the number of motions also. The stools were throughout very watery and slimy and during the first few days the smell was very offensive. The number of movements during the 24 hours varied from eight to 12, each being accompanied by severe abdominal pain. I tried, amongst other drugs, bismuth subnitrate, but it was at once thrown up. In this state the child continued until the 9th when the number of motions and the pain became greater and in the afternoon he had severe convulsions which were, however, controlled by bromide of potassium. On the 11th the convulsions returned, requiring more bromide. The child was now in a very serious condition, the tongue being dry, red, and raw, the abdomen tense and tender, and a painful movement of the bowels taking place every hour or oftener. I had more than once dropped the opium for a short time, but only with worse results. On the 12th I adopted a new line of treatment, washing out the large bowel with a hot weak antiseptic. I decided to wash out the bowel on account of the great success of this method in cases of acute dysentery in South Africa, as many of us when serving there as civil surgeons had found. I used a solution of permanganate of potassium, about a teaspoonful in a pint of water. The child was held on the mother's lap on his side, and 12 ounces of the hot solution were forcibly injected into the rectum with an ordinary Higginson's syringe. It was impossible to inject a greater quantity, as this amount was only injected with great difficulty and very slowly owing to the violent efforts of the child to expel it. On the nozzle being withdrawn the fluid was immediately shot out in all directions. I then in the same way injected about eight ounces more, meeting with the same opposition and result. The child seemed none the worse and I stopped all medicines from that moment.

The subsequent history was as follows. The child had no more pain or diarrhoea, and seemed very comfortable when I went away shortly afterwards. He soon fell asleep and in the afternoon had an easy movement of the bowels, formed and natural in all respects and without any of the previous straining or pain. During the night he slept well and on the morning of the 13th the mother told me that he laughed for the first time since he had been taken ill. On the morning of the 14th, the tongue being moist and clean and the child comfortable in all respects, he resumed small quantities of the prepared food which he had previously been taking. In the evening, no movement of the bowels having taken place for 48 hours, one drachm of castor oil was given and two

<sup>4</sup> Mainzer, see Velt, *loc. cit.*

drachms more were administered the following morning, as the first had taken no effect. The bowels were twice moved the same day. Except for the emaciation and weakness the infant now seemed to have quite recovered, his digestive tract causing him no more trouble. For a week or two he was naturally weak, but two or three weeks later he was quite strong and since then has had no relapse.

The advantages of the above method are quite obvious. It is easily and quickly carried out, is quite safe, and is very speedy in its results. My only regret in the above case was that I had not adopted the final treatment much earlier. For the future, if correction of the diet and the administration of some simple antiseptic is not followed by immediate beneficial results, I shall at once wash out the bowel in the manner described.

Liverpool.

## SOME OBSERVATIONS ON CERTAIN TROPHIC HINDRANCES TO BONY GROWTH.

By HEATHER BIGG, F.R.C.S. EDIN.

SOME time ago Sir William Gowers asked me if I had any facts recorded in my notes which would enable the question to be answered. "What is the difference in the rate of hindrance to growth of bone in infantile paralysis as years go on?" And again, quite recently, he wrote to me to know if I had ever met with a case similar to one which he "had lately seen in which in a year or two there was considerable elongation of the paralysed leg and it had clearly occurred at the hip-joint." This latter question is somewhat cognate with the former and I might readily have answered both from my own recollected experience, but as the subject which he suggested seemed one of very great interest I determined to make a complete analysis of my measured records of cases of infantile paralysis over the last 20 years and the results so obtained are indicated in this paper.

I should state that in all cases in which I have found that the limbs required mechanical appliances I have invariably been in the habit of taking, in addition to careful measurements, an accurate outline tracing of the limb on a sheet of brown paper. When these tracings have accumulated over some years they have been sorted and those that have ceased to be of further service have been destroyed. I have recently gone over and destroyed some thousands of superannuated tracings that have accumulated since 1880, and out of these I picked the tracings and measurements of 590 cases of infantile paralysis which seemed suitable for the investigation which Sir William Gowers had suggested. I found that a very large proportion of these cases had been sent to me by himself, by Sir J. Russell Reynolds, and by Dr. Julius Althaus, and that in the older instances I had complete records of dimensions extending from earliest childhood up to the adult termination of bodily growth.

For the purposes of correct comparison I have taken only the lower limbs as the basis, and I have selected solely those cases that are unilateral in order that the irregular growth of the affected limb might have the regular rate of growth of the sound one as a definite standard for distinction. Moreover, as regards dimensions I have disregarded all minor measurements, circumferential or otherwise, and have taken as the simplest index the difference between the lengths of the two limbs from the iliac crests to the ground-surface of the heels. In other words, the record that I have selected as the figure for analysis is that amount of heightening that it is necessary to superadd to the heel of the shorter limb in order that the pelvis may be rendered truly level at its iliac crests when the patient is standing with straight legs. It is true that in many cases I have also taken the boot-maker's records of the respective lengths of the feet as adjunctive data; but only for confirmatory purposes, as a foot-length is scarcely a reliable index of growth, seeing that a paralysed foot will often be spuriously lengthened by the falling and flattening of its arch.

In an ordinary case of infantile paralysis such as is most commonly met with it is at the outset the motor failure that is principally obvious, and as a rule it is this alone that draws attention to the nature of the disease, whether the motor failure be shown by a complete loss of power in

a limb or only by such slight difference in the balance of muscular power as merely leads to some little peculiarity of gait. But from the onset of the disease up to the adult termination of growth there becomes evident (apart from muscular wasting) a distinct trophic hindrance to bony development, and the question that I have sought to answer in my measured analysis of close on 600 cases is, What is the prospective amount and the relative duration of this hindrance during the whole period of bodily growth? I may say at once that the cases separated themselves into three distinct groups which I will first enumerate and then consider in detail. These groups are as follows: (1) cases in which the trophic hindrance continues during the whole period of bodily growth up to adult age and in which the difference in length between the sound and the affected limbs continues progressively to increase during that period; (2) cases in which the hindrance lasts only for a time, after which both the sound and affected limbs continue to grow at the same rate and the then existing difference between the two remains stationary; and (3) cases in which after the hindrance has lasted for a time and then ceased the affected limb tends to catch the sound one up in growth and in some rare instances actually does so, so that the difference between them is either diminished or even extinguished.

*Group 1.*—The cases which fall into this first group and in which the trophic hindrance is continuous throughout the whole period of bodily growth are by no means the commonest. The amount of loss in length varies and may be anything between three-quarters of an inch up to three inches, and even in rare cases more than this. The rate of hindrance to growth is generally even—that is to say, the heightening that has to be added to the shorter limb in order to keep the iliac crests level is superadded by regular increments during growth. Even with this trophic hindrance considerable motor recuperation may take place; and although from this it is clear that the trophic and motor changes bear no absolute relationship to each other, yet it is likewise a fact that those cases in which the original motor incapacity is the severest are generally those in which the trophic hindrance also becomes most marked, this probably being so because a more insuperable stretch of spinal cord has been (cicatricially?) involved. I notice also that the worst cases of which I have records are those that originated 30 or 40 years since—a fact that seems to show that more modern treatment goes a long way towards checking the severer results of the disease.

*Group 2.*—This group comprises what nowadays are the commonest cases—those in which the trophic hindrance comes to an acme, after which it wanes off into cessation and the two limbs continue their growth at an even rate together. For instance, if a child is attacked at two years of age and the heightening necessary to keep the pelvis level is added by increments of an eighth of an inch (that being my usual fraction of measurement) these additions are at first rapid and regular, then less so, and finally, at perhaps the age of 10 years, when the difference in the limbs may have reached from five-eighths to seven-eighths of an inch, no further addition is ever needed to be made. In brief, it would seem as if the trophic blockage in the spinal cord became gradually permeable and finally cleared.

Now, when I notice the very considerable shortenings that were common half a century since (as I find them recorded in my father's case-books), and when I see that the shortening nowadays is, on the average, much less, I can only conclude that modern treatment has had a great deal to do with this. Most of the cases of which I have kept records during the last 20 years odd have been under various medical treatments by medicine, massage, electricity, warmth, and the like, according to the special views of those who sent them to me, and, moreover, the mechanical treatment has materially altered. In the old days a completely paralysed limb was encased in a rigid instrument from hip to heel, and whilst easy walking became by such means immediately possible all muscular movement was precluded, and, as a consequence, no motor stimulus was ever sent through or against the block in the spinal cord. But nowadays the rightful treatment is afforded by giving the paralysed muscles only the exact amount of elastic assistance which they require, and in the efforts of walking and balancing the trophic and motor blockages in the cord tend to clear. The consequence is that not only does the trophic hindrance frequently terminate, but in a large number of instances the motor power is gradually restored from the thigh downwards and

the helpful instrument that originally extended to the hips is able to be removed piecemeal as the case progresses.

**Group 3.**—In this group are comprised those rarer cases in which after retardation has ceased there is a positive recoupment in growth. My attention was first drawn to this some 15 years since in the case of a boy whose affected foot and leg, during his later and athletic school-days at Rugby, gradually began to catch up its fellow, and since that time I have carefully watched for and have noted similar instances in which recoupment was either partial or even complete. The process seems to be in some way analogous to those common examples in girls in whom one breast will develop some time before the other, and yet the latter when it starts will catch up to its fellow and both will finally be of the same size. What the explanation is in cases of infantile paralysis I must leave to pathologists and content myself with only recording the facts.

Now, all the cases that I have just grouped are cases of ordinary infantile paralysis and they are largely dealt with by authorities on the nervous system, as it is the motor failure that so necessarily calls urgent attention to the disease. Trophic failure, as I have said, is also their usual accompaniment, but it bears no distinct relation to motor incompetency. It is therefore to be expected that there would be a malady in which trophic failure exists alone, and such is indeed so. Only as these cases have no disturbing motor drawbacks they are not taken to the nervous-system specialist, but are usually only to be detected by those who find them as one of the causes of extrinsic lateral curvature of the spine where the pelvis is tilted out of place by the shortness of an undergrown limb. In the *British Medical Journal* of April 6th, 1895, I briefly drew attention to what I took to be an unrecorded fact—that the shortening of a leg was very often “due to a retarded nutrition of one side of the body by what might be called *infantile trophic paresis*.” To this statement I may now further add that I have observed that the trophic hindrances are the same as when this trophic incompetency is conjoined to motor infantile paralysis, and they drop into similar groups.

It is obvious that where trophic paresis causes the shortening of one leg it is unilateral; but I have good grounds for knowing that bilateral cases are not uncommon, although I have usually detected them when examining the legs for something quite different. The evidences are as follows. The lengths of all parts of the body have a distinct relationship well known to sculptors and those who measure the body accurately. If the length of an arm or of a foot be given the lengths of all other parts of the body can be readily estimated; hence if the length of a child's thigh-bone from the great trochanter to the knee is found to be nine inches it is known that the measure from the knee to the heel should be 11 inches. In a normal body the relationships are always exact, but every now and then, generally in examining a case of knock-knee, I have found a gross discrepancy of proportion to exist—as, for example, the legs from knee to heel might be an inch or so less in length than they should be. And, further, in keeping a continuous watch on these cases I have found that the same grouping of hindrance is apparent—that is to say, that sometimes the entire disproportion will disappear during growth, sometimes it will be diminished, and sometimes it will persist.

In concluding these observations I may add a few words on Sir William Gowers's second question respecting his case of elongation of a paralysed leg “clearly occurring at the hip-joint.” If Sir William Gowers had not accentuated this latter point I should have been inclined to hold that the case was one of those which I have classed in Group 3. I can only say that I have never observed such a case as his. I have, however (as others may have done), noticed cases of shortening at the hip from injury without disease and have known them to be accidentally diagnosed as paralytic. To give an instance, a girl, eight years of age, was brought to me the other day who two years previously had fallen violently down on her right hip. After the bruise over the trochanter had cleared away nothing wrong was noticed, but a few months later she began to walk queerly. A diagnosis of infantile paralysis was made and a course of massage was ordered which had been excellently carried out for a good many months when the parents brought the child to me for an opinion. The condition was this—the right trochanter was three-eighths of an inch higher than its fellow and not sufficient for dislocation, but the lengths of the bones were similar in both legs and there were no evidences of

motor or trophic paralysis. It seemed clear, then, that the original injury had caused some inflammatory softening in the neck of the soft bone of the child and that this had yielded under the weight of the body in walking into a more obtuse angle than its fellow. A skiagraphic inspection confirmed this view. But the result of the excellently conducted massage had been to increase the circumferences of the originally injured limb to over half an inch in excess of its fellow. The case was interesting as it showed beautifully the trophic effects of massage on a limb that was in complete health. Such an experience, if instructive, is rather rare.

Wimpole-street, W.

## Clinical Notes:

### MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

#### CANCERUM ORIS WITH ITS COMMON COMPLICATIONS.

BY R. CAMERON, M.B., CH.B. EDIN.

CANCERUM oris, though fortunately such a rare disease in comparison with other varieties of stomatitis in children, admits of no reasonable mistake in diagnosis. The distinctive macroscopical character of the lesions, the discolouration of the tissues involved, and the fœtid smell from any part of the surface abraded, present a picture typical of the disease as it is described in the text-books. The only two cases which have come under my notice were by a strange coincidence admitted into hospital during the same week, the one having an exceedingly rapid course from start to finish and the other after a mild incidence and rather chronic course (for this affection) becoming suddenly complicated by heart failure.

**CASE 1.**—The patient was a female child, aged three years. Three weeks before admission she had developed measles. This disease ran a mild course, though the hygienic conditions were apparently of the worst. A week before bringing her the mother noticed a black spot on the right side of the mouth, on the inner surface of the cheek. This was still present on admission as a dry adherent slough, from the buccal angle extending outwards for about half an inch. In addition, however, the left cheek was now necrosed, putrid, and emphysematous from the lips to the ascending ramus of the jaw, and on the gum above the second upper incisor on the left side was a soft putrid slough. At this point a probe could be inserted and could easily find its way between the gum and the superior maxillary bone. The child was suffering from acute septic poisoning and was in a comatose condition, but there was no evidence of pneumonia, nor was there any lesion of the vulva. All the necrotic tissue was separated with scissors, the surrounding parts were scraped with the sharp spoon, and a little nitric acid was applied on a dry sponge, taking care to prevent this from injuring sound tissue. Within a few hours the remainder of the upper gum became soft and pulpy, and on being removed showed the superior maxilla to be necrosed and irregular and green in colour. The pus, which was plentiful, stained the cottonwool and sponges a bluish-green colour. The child died about 20 hours after admission.

**CASE 2.**—A woman, aged 46 years, was admitted with two black gangrenous spots on the inner surface of the right cheek; one involved the right angle of the mouth and the adjacent portion of the lower lip, and the other was on the buccal surface opposite the two upper bicuspid, but neither involved the whole thickness of the cheek. The surface was exposed, and under chloroform the affected portions were carefully and completely removed and nitric acid was afterwards applied. On the following day a new area showed itself posteriorly to the site of the original sores. This was again treated in the same way, except that carbolic acid was applied instead of nitric acid. During the following night symptoms of heart failure appeared, and in spite of digitalis, ether injections, and alcohol death resulted. No new focus had appeared, pneumonia was not present, and the pudenda showed no sign of noma.

Absorption of carbolic acid was suggested as the cause of the collapse, but I see no reason to regard that as probable, and the urine which was withdrawn was in no way abnormal. The disease had been slowly progressing for a fortnight before surgical interference. The patient suffered from pulmonary emphysema and was addicted to alcohol.

In a very large proportion of cases of *cancrem oris* pneumonia or noma, perhaps combined with gangrene of the anus or pneumonia and noma together, appear as complications. Of 173 cases described in the *American Journal of the Medical Sciences* as occurring in a recent epidemic more than one-fifth had one or other complication or both combined. These complications may accentuate the constitutional effects or may introduce a further antagonist to the patient's power of resisting the disease, but from its position and its virulence and rapidity it must always prove exceedingly dangerous to the life of the individual attacked. The patient is always one with a constitution debilitated by disease or habit of life. With this weakened organism we have the disease in a position where, though the nutrient supply of the tissues is abundant, there is also an abundant absorption. Toxalbumins and bacilli will rapidly pass into the blood, and it is reasonable to suppose that in many cases septic emboli and thrombosis may extend through the veins to the cavernous and other sinuses. In nine bacteriological examinations carried out during the American epidemic a leptothrix was found constantly present, but it is impossible to fulfil all the laws which are required to prove this to be the distinctive organism of the disease. Probably it is a mixed infection, for there are always numerous other bacilli and cocci present, and in one of my cases the colour of the pus was distinctly bluish-green, as it would be under the influence of the bacillus *pyocyaneus*.

Cardiff.

#### A CASE ILLUSTRATING THE EFFECTS OF PRESSURE ON EARLY SYPHILITIC WARTY GROWTHS.

BY ARTHUR SHILLITOE, M.B. CANTAB., F.R.C.S. ENG.,  
SURGEON TO OUT-PATIENTS TO THE LONDON LOCK HOSPITAL.

At the October meeting of the Dermatological Society of Great Britain and Ireland I showed a young man with papillomata and condylomata present at the same time on the tongue. He gave the following history. Gonorrhoea was acquired about Christmas, 1900, followed by a chancre on the penis in January, 1901. He was treated privately from January to July and had had no eruption on the body to his knowledge. In June last he had warts on the penis which were destroyed by caustics.

According to Mr. J. Hutchinson, sen., if warts should be found on the penis of a syphilitic subject, the tongue should always be examined for a like condition; and, if present (which they often are), they will be seen to be situated on the posterior third of the dorsum between the arms of the V formed by the circumvallate papillae—that is to say, on that part of the tongue which does not come in contact with the palate and therefore is not subjected to pressure. While agreeing with this—viz., the formation of papillomata on a part not subject to pressure—one cannot but remember how often in venereal patients (both gonorrhoeal and syphilitic) are seen large masses of warts beneath a tight or phimosed prepuce where the pressure must be fairly constant and considerable. On examining my patient I found that he certainly had a few small warts about the corona and on looking at his tongue there were seen several papillomatous growths in the position above indicated. In addition, scattered over the anterior two-thirds of the dorsum and the margins of the organ were eight or 10 large, flat-topped, white condylomata, with sharply defined margins—that is to say, on that part of the tongue which is subject to the intermittent pressure of the palate and teeth. When we consider the positions of condylomata in other parts we find that they, too, occur in situations subject to intermittent pressure—e.g., the natal fold, the inner aspect of the thighs, and the sides of the scrotum.

It seems to me that (1) pressure, as seen in the case of a phimosed prepuce, and (2) no pressure at all, as in the posterior third of the dorsum of the tongue, exert an equal influence in determining the formation of ordinary-looking papillomata; whereas, if the pressure be intermittent, as seen in the anterior two-thirds of the tongue, the inner aspect

of the thighs, and the sides of the scrotum, or in the natal fold, then these papillary hypertrophies assume a condylomatous form.

In conclusion, my patient told me that his tongue was in much the same condition last July and that it yielded so rapidly to treatment that he took no further medicine, until I saw him at the hospital early in October, when the lesions speedily disappeared under mercury.

For permission to publish the above case I am indebted to the Dermatological Society of Great Britain and Ireland.

Frederick-place, E.C.

#### NOTE ON A CASE OF CONGENITAL ATROPHY OF THE RIGHT KIDNEY.

BY R. NIVEN, M.B., CH.B. GLASG.,

ASSISTANT MEDICAL OFFICER, BETHNALL HOUSE ASYLUM, LONDON, N.E.

A MAN, aged 57 years, died at Bethnall House Asylum on Nov. 9th, 1901, from asthenia consequent on general paralysis of the insane, complicated by hypostatic engorgement of the lungs. At the necropsy no trace of the right kidney could at first be discovered. On removing the right suprarenal capsule, however, a small reddish mass of about the size of a scarlet-runner bean was discovered embedded in the surrounding areolar tissue and close to the lower margin of that organ. The connexions with vessels and ureter were thus unfortunately severed before a careful dissection was made. A small vessel, probably a vein, was found emerging from the inner border of the reddish body. A very small artery, probably the right renal, came off the abdominal aorta opposite to, and on a level with, the left renal artery. On dissection, a fine tube was found following the normal course of the ureter and was traced downwards to the bladder which it entered at a point on the right side of that organ corresponding to the point of entry of the left ureter on the other side. A stout hairpin was with difficulty passed through a small surface at the right posterior angle of the trigonum vesicæ, and it travelled along the tube for about two inches. On microscopical examination the reddish mass embedded in fat had the structure of very atrophied kidney substance. A few tubules were seen to be scattered through an abundance of dense fibrous tissue. They were lined with flattened epithelium and were filled with retained secretion. The vessels in the dense fibrous stroma were very thick-walled. The right kidney exhibited some degree of compensatory hypertrophy. Its position and relations were normal. The organ weighed seven ounces, it was of healthy colour and apparently normal on section, and the capsule stripped easily. Microscopical examination showed the kidney to be practically healthy. There were small patches of fibrous tissue here and there, but the glomeruli were not degenerated and the convoluted tubules were not dilated. The urine was neither measured nor examined during life, as the man was during the period of his residence here indifferent to the calls of nature and passed urine and faeces under him. Throughout life there were no symptoms indicating defect in the urinary organs.

For permission to publish this case I am indebted to the kindness of Dr. J. Kennedy Will, medical superintendent of the Bethnall House Asylum.

Cambridge-road, N.E.

#### A NOTE ON A CASE OF PURPURA.

BY T. EDWARD SANDALL, M.B., B.C. CANTAB.

A WELL-MARKED case of purpura is perhaps sufficiently rarely met with in general practice as to warrant a brief report. The following case is of interest on account of the peculiarity and duration of the premonitory symptoms which completely puzzled me at the time, and until I saw the characteristic eruption on the ninth day of the illness I had no idea that I was dealing with a simple case of purpura.

The patient was a girl, aged 15 years, who had always enjoyed good health but had not yet menstruated. I first saw her on Nov. 11th, 1901, when she complained of acute pain in the calf of the leg and in the popliteal space on both sides which, having begun the day before, became so acute that she was quite unable to walk and she had to crawl upstairs to bed on her hands and knees. There was no other symptom; the temperature was normal, the appetite was good,

the tongue was clean, and the bowels were regular. On examination there was no abnormal appearance of the skin and no swelling or oedema, but there was acute tenderness on pressure on the calf of the leg and in the popliteal space. Lying perfectly still the patient was free from pain, but any attempt to flex the leg was acutely painful. She was kept in bed, hot fomentations were applied to the parts affected, and a mild aperient was given, but no other medicinal treatment was employed as I saw no indication for it. Next day the patient was better, feeling quite well in herself and complaining much less of the pain and tenderness. On the 13th she declared herself well again and got up for a few hours in the afternoon, but this appeared to cause a return of the pain and on the 14th it was worse, especially in the right leg; the right arm and elbow were now affected and there was some headache. Although the temperature remained normal, the tongue clean, and the joints free from swelling, I thought that the symptoms pointed to subacute rheumatism. The patient was therefore kept in bed, the affected parts were wrapped in flannel, and a salicylate of soda mixture was given. During the night of the 14th the patient vomited several times and again on the morning of the 15th, when the tongue was slightly furred and the headache continued, but the pain in the limbs had practically subsided. On the 16th the patient declared herself to be quite well again, and on the 17th treatment was discontinued, and she returned to her duties as a domestic servant. About 10 P.M. on the 19th I was sent for and I found the patient in bed, complaining once more of acute pain in the arms and legs which had begun in the afternoon. The skin was covered with a purpuric eruption, the spots varying from the size of a pin's head to about one-eighth of an inch in diameter or larger. They were most abundant on the limbs and were absent from the face. I was informed that a slight rash had appeared the day before and had faded again. The temperature was 102° F. There were slight oedema of the legs and feet and some effusion into the ankle-joints, particularly the right. On the 20th a few fresh spots had developed, but the general rash was fading; the spots were dull and purple in colour. The pain was less severe and the oedema was less marked. On the 21st the patient felt quite well; there was no longer any oedema or effusion into the joints, there was no pain or discomfort, and the rash seemed to be fading slowly. Improvement continued for the next two days, when the patient left for her own home, and passed out of my observation.

On the pathology of purpura, which is a difficult subject, I do not propose to touch, but I desire to call attention to one or two points as to causation and diagnosis. In the first place, had the non-appearance of the menstrual function any effect in the causation of the attack? There was absolutely no cause, as generally given in our text-books, and I am unable to refer to literature on the subject. The patient was a strong, healthy girl, taking plenty of outdoor exercise, and she had never had any serious illness. The diagnosis of purpura is easy enough with the rash before one's eyes, but the symptoms preceding the eruption were very puzzling and, I think, unusual. What was the cause of the acute pain and tenderness in the limbs? If the term "rheumatism" will cover these symptoms and if the eruption may be termed "purpura rheumatica," I still would urge that there was not rheumatism in the ordinary acceptation of the term. And what were the structures affected? Was the pain neuralgic or muscular? Lastly, I would call attention to the temperature, which remained normal during the whole illness except for a few hours at the onset of the eruption, when it reached 102°.

Alford, Lincolnshire.

**BRISTOL HOSPITAL SUNDAY FUND.**—A meeting of the committee of the Bristol Hospital Sunday Fund was held on Dec. 12th. The Lord Mayor gave an account of the progress of the fund, showing that in 1898 there were 92 collections at places of worship which realised £1128, whereas in 1901 there were 251 collections and £1772 were raised. Grants of £1711 were made to the local medical charities, which included the Royal Infirmary, £704; the General Hospital, £591; the Children's Hospital, £218; and the Eye Hospital, £105. It was decided that the last Sunday in January next should be observed as Hospital Sunday.

## A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

*Nulla autem est alia pro certo nocendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.*—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

### NOTTINGHAM GENERAL HOSPITAL.

A CASE OF TRAUMATIC ANEURYSM OF THE VERTEBRAL ARTERY; FAILURE OF LIGATURE ON THE PROXIMAL SIDE; DISTAL LIGATURE; EXCISION OF THE SAC; PLUGGING; RECOVERY.

(Under the care of Mr. A. R. ANDERSON.)

THE treatment that is theoretically correct for a traumatic aneurysm is identical with that for a recent wound of an artery, that is, ligature on both sides of the wound; and the only exceptions that are admissible are cases where it is impossible or unadvisable to apply these two ligatures. It is generally acknowledged that the internal carotid and its branches form the chief exception to the rule and that with these proximal ligature may prove sufficient, but the vertebral artery from its depth might fairly claim to be also considered unsuited for the usual treatment. The circle of Willis, however, supplies the distal portion of the vessel so freely with blood that it must be acknowledged that ligature on both sides of the wound, or on both sides of the traumatic aneurysm, is imperatively necessary. The following report describes the successful treatment of a most troublesome traumatic aneurysm of the vertebral artery immediately below the third cervical vertebra.

A young woman, aged 21 years, was taken to the Nottingham General Hospital on Sept. 4th, 1900, having been stabbed in the neck a short time previously. The injury was inflicted by the small blade of a penknife used for nails and having only a short portion of blade at the end. A small wound, one-third of an inch long, was found over the posterior border of the sterno-mastoid on the left side, about the level of the upper border of the thyroid cartilage; its direction was forwards and inwards. There had been profuse bleeding, arterial in character, and the patient was pale and faint from loss of blood on her arrival. It had then ceased. A pad was placed over the small wound which healed readily and gave no further trouble, and at the end of three weeks she went out apparently well.

On Jan. 2nd, 1901, the patient was readmitted to the hospital with a pulsating swelling in the neck, of about the size and shape of a duck's egg, having its centre opposite the wound. Its upper limit extended as high as the lobule of the ear and its lower limit to within two inches of the clavicle. The pulsation was markedly distensible and a loud bruit could be heard on auscultation. No information could be gained by digital compression of the common carotid artery, the bulk of the tumour interfering with this, and any deep pressure caused the patient much distress. From the situation of the aneurysm and the direction of the wound it was thought probable that the injured vessel was the carotid artery or one of its branches, and on Jan. 4th Mr. Anderson made an incision over the course of the common carotid artery and exposed this vessel, and was somewhat surprised to find that compression of it produced no effect whatever on the pulsation in the aneurysmal sac. It was then concluded that the vessel involved must be the vertebral artery, so the incision was prolonged downwards and this vessel was exposed in the interval between the longus colli and the scalenus anticus, just below its entry into the foramen in the transverse process of the sixth cervical vertebra. Compression of the vessel here immediately and completely arrested the pulsation in the sac. The vessel was then tied with a silk ligature and the wound was closed.

The operation was followed by contraction of the pupil of the corresponding side, due to disturbance of the sympathetic filaments in relation with the artery. In the absence of other evidence this affords proof that the operator had ligated the vertebral artery, and not the inferior thyroid

artery, which lies in front of, and may be mistaken for, it. For a few days all went on well and the wound healed by first intention. Within a fortnight, however, it was seen that the operation had failed to cure the disease, as the aneurysm was pulsating again, with but little diminution in its expansile beat, the failure being no doubt in great measure due to the free anastomosis through the circle of Willis.

On March 14th Mr. Anderson operated again, making a long incision over the sac, which was dissected round and isolated as much as possible. His original intention was to endeavour to chisel away the transverse processes and to find and to tie both ends of the wounded vessel. This obviously could not be done without the removal of the sac, which lay over them from the axis to the sixth cervical vertebra. The sac was therefore incised preparatory to this, but there followed such a rush of arterial blood as to necessitate its continuous compression and to put any deliberate operative procedures in the vicinity of its neck out of the question. The hæmorrhage was readily controlled by pressure of the finger within the sac, which was undertaken by Dr. J. Milne, the house surgeon, and no more blood was lost from this source. The incision was then prolonged upwards and backwards, in a curved direction towards the occiput, and after the trapezius, sterno-mastoid, splenius capitis, and complexus muscles had been divided near their attachments the distal part of the vertebral artery was tied in the sub-occipital triangle, just where it enters the groove behind the transverse process of the atlas. The difficulties were considerable. The upper border of the sac came within the area of the operation, and although drawn down as much as possible with a retractor the deeper dissection had practically to be carried on behind it. Another trouble was from unnamed, but considerably dilated, arterial branches of which a regular plexus was encountered. After the ligature had been placed round the vessel Dr. Milne removed the pressure which during this time he had been keeping on the mouth of the sac and the operator was disappointed to find that even then the bleeding was not completely arrested. It was, however, quite different from what it had been before the distal ligature. There was now no rush or pumping of blood, but still a distinct welling up of arterial blood from the neck of the sac. The sac was then cut away. Two courses now remained—either to remove the transverse processes and to search for, and to tie the ends of, the vessel, or to plug the neck of the sac, which lay between the transverse processes of the third and fourth cervical vertebrae, at which spot the vessel had been wounded. Although the former course was surgically correct various considerations induced Mr. Anderson to employ the latter. In the first place the patient had lost a good deal of blood and was already beginning to feel the effects of a prolonged and difficult operation which it was desirable to bring to as speedy a termination as possible. Further, it was apparent that even moderate pressure controlled the blood now flowing which had no force behind it. The third point which induced him to resort to pressure was obtained from the anatomy of the parts involved. The vertebral artery in its course through the neck gives off numerous lateral branches which pass out between the transverse processes and form a plexus, anastomising above with the princeps cervicis from the occipital artery and below with the profunda cervicis from the superior intercostal artery. This was now the only source left from which blood could be supplied to the interior of the sac. It forms the only collateral circulation after ligature of the vertebral artery, excluding the direct route through the circle of Willis. These vessels had no doubt become enlarged as the result of the ligature of the vessel at the root of the neck, but making allowance for this it was considered very improbable that they could furnish a supply of blood which would not be arrested by such direct pressure as could now be employed. The site of the neck of the sac was packed with strips of sterilised lint dusted with iodoform and the wound was closed except at this spot. The plug was left in position for a week, at the end of which time it was removed, and the cavity was lightly packed with iodoform gauze. The wound, except at this spot, healed by first intention and the patient made an uninterrupted recovery. The movements of the neck and shoulder are highly satisfactory, those of the latter being practically unimpaired.

*Remarks by Mr. ANDERSON.*—Aneurysm of the vertebral artery in the neck, traumatic or other, is of so rare occurrence that it may be looked on as a clinical curiosity. As there is, however, some information to be obtained from this case

which might be helpful in treating a similar one I have thought well to record it. Thus it is evident that ligature of the vertebral artery on the proximal side cannot be relied on to arrest bleeding from a wound of the vessel or to cure a traumatic aneurysm, although it is possible that in another case it might be successfully employed. Literature of wounds of the vertebral artery is scanty, but a great deal has been written concerning wounds of the branches of the other great vessel of the neck, the common carotid artery. Some years back I collected and tabulated in a paper read before the Nottingham Medico-Chirurgical Society 116 cases in which the common carotid artery had been tied for hæmorrhage from one of its divisions, or branches thereof, and of this number 18 died from recurrent hæmorrhage from the seat of injury. Several of these were instances of wound of the internal carotid artery, which is a larger vessel than the vertebral and has a very direct communication at the base of the skull with the vessel of the opposite side. Judging, therefore, by analogy, the percentage of failures in the case of the vertebral artery should be less than that of the carotid. I insisted, in the paper referred to, on the importance of using every endeavour (especially in wounds of the internal carotid artery from the mouth), to find and to tie both ends of the injured vessel, in accordance with the recognised surgical axiom which applies to arteries in other parts of the body, and I should have been glad to apply this principle in the case narrated but found it impossible to do so under the existing conditions.

Compression of the carotid artery as a means of diagnosis was not obtainable owing to the bulk of the tumour and the suffering which it occasioned, and when I began the first operation I thought that the aneurysm was probably connected with one of the main branches of the common carotid artery, and my intention was to arrest the flow of blood through it by temporary compression of the common trunk, then to excise the sac, and to tie the ends of the communicating vessel. This was impracticable on finding that the vessel involved was the vertebral artery. After ligating it at the root of the neck the flow of blood into the sac was practically stopped, as evidenced by the cessation of pulsation and the shrinkage in its bulk. It would at that time have been possible to excise the sac, to cut away the transverse processes, and to find and to tie both ends of the vessel at the seat of the lesion. On the other hand, the result at the moment appeared to be highly satisfactory, and the getting at the wounded vessel would have involved a somewhat serious and difficult operation. Further, there seemed to be a reasonable prospect of success afforded by the knowledge that ligature of the common carotid artery has been frequently (although by no means invariably) successful for wounds of the internal carotid artery and that the anatomical conditions alluded to above were all in favour of the vertebral artery. The development of the collateral circulation in the month that intervened between the two operations, with the consequent number of unnamed arteries of respectable size that were met with during the operation, was quite remarkable and is worth more than a passing notice.

## GOVERNMENT CIVIL HOSPITAL, HONG-KONG.

### A CASE OF RUPTURE OF THE INTESTINE; ABSENCE OF SYMPTOMS FOR SOME TIME AFTER.

(Under the care of Mr. J. BELL.)

THERE are two points in connexion with the following case which are of importance. In the first place, it will be noticed that the defence advances the statement that spontaneous rupture of bowel can occur. The passage on which the defendant's counsel relied was taken from a work by Dr. Francis Ogston.<sup>1</sup> The exact words are as follows: "It is to be kept in view by the medical jurist that in some cases death happens very suddenly from a spontaneous rupture of some part of the bowels, even without any previous disease." Dr. Ogston was a very careful observer and therefore great weight may be attached to what he has said, and doubtless the statement quoted above was founded on some case or cases he had met with; but it must be borne in mind that the observations on which this statement

<sup>1</sup> Medical Jurisprudence, 1878, p. 468.

is based were made many years ago, and our improved methods of observation might show the presence of previous disease where formerly it would not have been noticed. In any case, the character of the rupture and its situation must all be taken into account in forming an opinion on its etiology. The second point that the case suggests is the length of time which could elapse after such a rupture without the appearance of symptoms. In the defence it was suggested that 36 hours might have passed without any symptoms appearing. This is certainly impossible. If symptoms do not occur at once it can only be because that part of the bowel chances to be empty at the time of rupture; but as soon as any contents pass into it from above extravasation must occur with its attendant signs and symptoms. Thus these might possibly be delayed for a few hours, but not for very long.

Whilst being arrested an adult Chinaman was kicked—so it was alleged by certain witnesses—by the native policeman who was making the arrest at 3 P.M. on July 24th. The man walked to the police-station and made no complaint until 5 P.M. when he said that he was in pain. He was removed by launch to the Government Civil Hospital, Hong-Kong, and on admission was in no pain or collapse. At 1 A.M. on the 25th he was in great pain, which seemed to be paroxysmal and was referred to the whole of the abdomen. His pulse was good and no dulness could be detected in either flank. At 5 A.M.—14 hours after the alleged assault—collapse set in suddenly and he died at 9 A.M.

*Necropsy.*—At the post-mortem examination no external bruise or extravasation into the muscles could be seen. The small intestine about one inch above, and to the left of, the umbilicus was torn almost completely across. The peritoneum was intensely congested, but no lymph was thrown out. Bile and intestinal fluid were found in the abdominal cavity, but no food was seen.

*Remarks by Mr. BELL.*—The defendant's barrister quoted Ogston as saying that medical jurists should remember that it is possible to get a rupture of a perfectly healthy gut without any cause whatever. This view I naturally declined to agree to, and I think that in any future edition of this work some explanation should be given or cases cited to prove this fairy tale. It was also set up in defence that the rupture had occurred in a fight 47 hours previously to death. This I declined to agree to in view of the extent of the peritonitis, which I took to be 12 or 18 hours old. The supposed assailant was acquitted by the jury.

## Medical Societies.

### PATHOLOGICAL SOCIETY OF LONDON.

#### *Cortical Localisation, with Special Reference to the Higher Apes.*

A MEETING of this society was held on Dec. 17th, Mr. W. WATSON CHEYNE, the President, being in the chair.

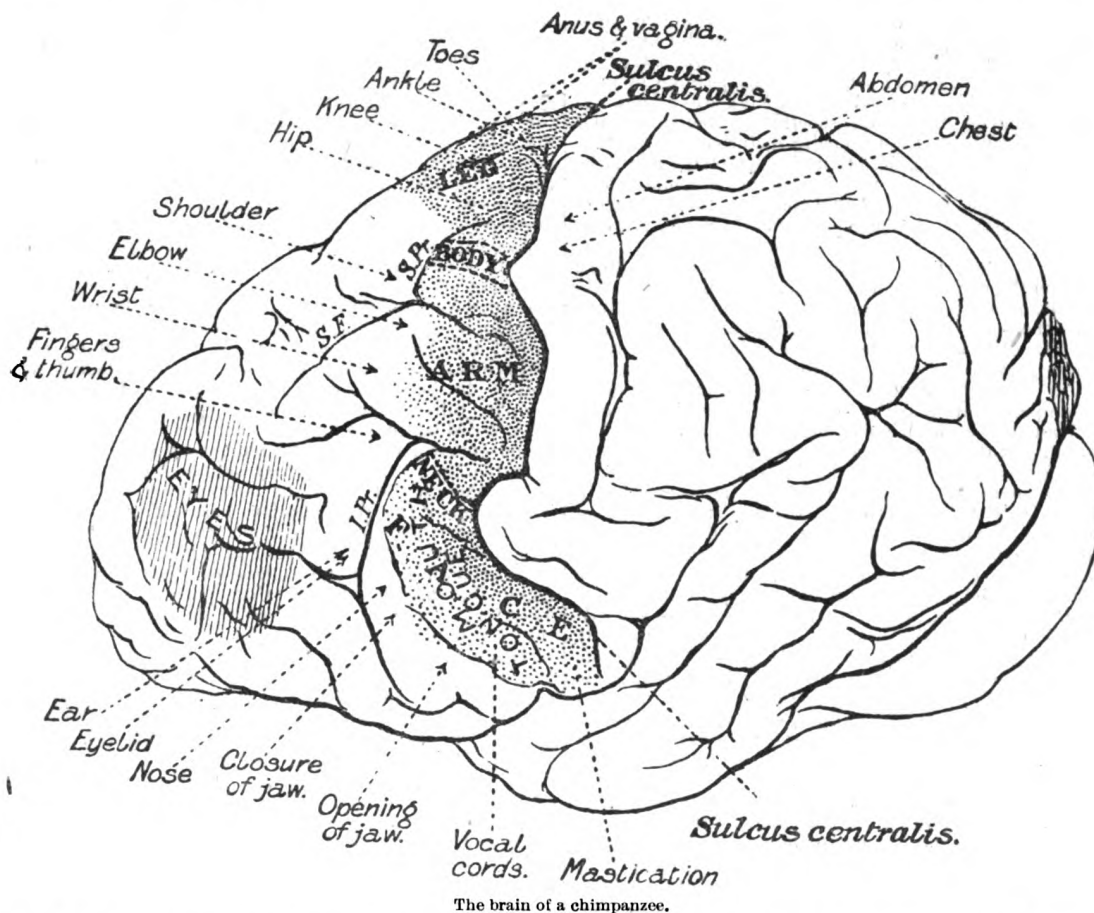

Professor C. S. SHERRINGTON read a paper on Cortical Localisation, with Special Reference to the Higher Apes. After referring to the influence which the work of Hughlings Jackson, Hitzig, Ferrier, and others had on the conception of the cortical centres, he said that considering the complex connexions which existed with the longer neurons it was remarkable that such accurate results could be obtained by methods which were comparatively rough. Eleven years ago Beevor and Horsley published the results of their experiments on the orang-outang and that had been the only anthropoid ape experimented on up to the present time. The brain in the anthropoid ape was at its highest development, except in man. The gorilla had the highest development, the chimpanzee was next, and this was followed by the orang-outang. Two species of chimpanzee had been experimented upon. The chief points of difference which had been observed with regard to the limits of the excitable area were that no excitable area could be found behind the Rolandic fissure and that the anterior boundary could not be defined by any definite sulcus. The anterior margin of the excitable area was very variable in individual apes. The position and size of the fissures were also liable to extreme variation—in fact, in comparing various specimens of brains hardly any two

were exactly similar. This frequency of individual variation was so great that a preserved brain could not be used as a guide to the localisation of centres in experimental work, and the function of the centre had to be determined by direct stimulation. The fissures of the cortex did not bear any relation to the boundary of function of the cortical centres, and the asymmetry in the sulci was often so marked that the topographical relation of the centres on two sides of the brain could not be determined thereby. If it were desired to excise the hand area the only exact method of localising it would be by electrical stimulation. It had been stated that the cortex of the ape responded less readily to electrical stimulation than the cortex of the lower monkeys, but in the experiments which had been performed this had not been found to be the case. The same strength of current which would produce a movement on stimulation of the cortex of a cat or of a bonnet monkey would also produce a similar movement in the chimpanzee. It had been stated by Beevor and Horsley that epilepsy could not be provoked by stimulation of the cortex; that statement was probably correct to some extent, but, on the other hand, epileptic discharges could be produced in certain individuals of the anthropoid apes. A chart was then shown indicating the position of the various centres (see figure). In the tongue area stimulation could not produce protrusion although almost all other movements could be produced. In the area for closing of the eye stimulation caused the eye on the opposite side to be firmly closed while that on the same side was less forcibly closed. An undescribed area representing movements of the trunk muscles had been mapped out between the leg and arm area and also an area concerned in the movement of the perineal muscles. No confirmation could be obtained of the area situated below the thumb centre and described by Beevor and Horsley as giving rise to movements of the head and eyes to the opposite side. The method that had been used in these experiments had been to place one electrode on the cortex, the other being attached as a bracelet to the wrist. The point used for stimulation of the cortex was a fine platinum point on a spring, so that undue pressure on the cortex was avoided. In not one of the experiments performed had any movement been obtained by stimulation behind the Rolandic fissure. In a chimpanzee the hand area was excised and a localised monoplegia resulted. There was no affection of the face or leg. The parts paralysed were the fingers, thumb, wrist, and shoulder, while the elbow escaped. This paralysis only lasted a week, and after a month the ape was able to feed itself with the formerly paralysed hand. A second operation was performed and on stimulation in the anterior corner of the old wound some movements of the hand occurred. This part of the cortex was removed but no further paralysis resulted from this excision, and two weeks later the ape was killed. On examination by Marchi's method degeneration was well marked in the ventral pyramidal tract, in the crossed pyramidal tract, and also in the uncrossed pyramidal tract, and this degeneration could be traced down to the upper lumbar region. In another experiment in which the leg area was removed no degeneration could be found in the ventral pyramidal tract. In a third experiment in which a large lesion had been made behind the Rolandic fissure no paralysis of any kind resulted and no degeneration of the spinal cord existed. In a fourth experiment with a lesion also behind the Rolandic fissure there was no descending degeneration. The gorilla showed the same general arrangement of centres as the chimpanzee. As had been pointed out by Beevor and Horsley the size of the motor cortex in comparison with the whole cortex was relatively smaller in the higher apes than in the lower animals, and since the area of excitable cortex was found to be smaller in the present series of experiments than in those of Beevor and Horsley this difference in proportion was yet more marked.

Dr. F. W. MOTT congratulated Professor Sherrington on his magnificent work which would be of great practical importance. He said that he had performed a necropsy on a patient who had suffered from a monoplegia of the arm and it was found that only a portion of the ascending frontal convolution was atrophied, such a fact tending to confirm the observation of Professor Sherrington that the excitable cortex lay in front of the Rolandic fissure. One other point seemed also to be in favour of this observation—viz., that the large Betz cells were all situated in the ascending frontal convolutions. He asked if Professor Sherrington had been able to trace the pyramidal fibres into the grey matter of the anterior horn, for Professor Schäffer had held that the pyramidal fibres passed into Clarke's column. He asked also whether

any fibres could be traced from the arm area to the occipital region, since such might be expected in the apes which had assumed the erect position. He had himself been able to produce movements of the head and eyes by stimulation in the region of the calcarine fissure.

region, and therefore this case could not be used as a definite proof of the point referred to by Dr. Mott. With regard to Dr. Beevor's observations, he said that his experiments fully confirmed Beevor's and Horsley's observations with regard to the position of the shoulder area. He did not think that

The brain of a chimpanzee.

Dr. C. E. BEEVOR said that the chief points in which the experiments of Professor Sherrington did not agree with those of Mr. Horsley and himself were with regard to the position of the shoulder, since in Professor Sherrington's experiments the shoulder was placed near the face centre, whereas in Mr. Horsley and his (Dr. Beevor's) experiments the hand was near the face centre. He said that some movements of the face and thumb had been obtained from stimulation behind the Rolandic fissure, and he thought that the difference in results might be accounted for by the age of the apes, since their ape was only two and a half years old.

Mr. C. A. BALLANCE said that he had performed some excitation experiments on the bonnet and rhesus monkeys, and had found that both the ascending frontal and ascending parietal were excitable. He had excised portions of the cortex corresponding to movements of the thumb, but had never been able to produce permanent paralysis. In one monkey he had by stimulation of the centre for the big toe on one side obtained movements of both toes, but on stimulation of the area in the opposite hemisphere no movement resulted, seeming to show that the big toes of the individual monkey were represented on one side only.

Dr. J. PURVES STEWART said that he had had the opportunity of stimulating the motor cortex in man in order to determine the situation of the centre for movements of the foot in a man who suffered from Jacksonian epilepsy, and he had been surprised to find that he could only obtain movement from stimulation of the cortex in front of the fissure of Rolando.

Professor SHERRINGTON, in reply, said that the degeneration of the pyramidal fibres could be traced into the grey matter of the anterior horns, but that in this case there was atrophy of the cells of the anterior horn in the brachial

region, and therefore this case could not be used as a definite proof of the point referred to by Dr. Mott. With regard to Dr. Beevor's observations, he said that his experiments fully confirmed Beevor's and Horsley's observations with regard to the position of the shoulder area. He did not think that

## CLINICAL SOCIETY OF LONDON.

*The Association of Moveable Kidney on the Right Side with Symptoms of Hepatic Disturbance—The Theory of Compensation in Disease of the Mitral Valve.*

A MEETING of this society was held on Dec. 13th, Mr. HOWARD MARSH, the President, being in the chair.

Dr. S. H. HABERSHON read a paper on the Association of Moveable Kidney on the Right Side with Symptoms of Hepatic Disturbance. In introducing this subject he defined the term "hepatic diathesis," and instanced three classes of patients in whom functional hepatic symptoms were liable to be set up—firstly, those of definite biliary susceptibility; secondly, those in whom biliousness was induced by circumstances well within their control; and thirdly, those in whom the hepatic symptoms depended on a ptosis of the kidney or the liver. The object of the paper was to emphasise the medical aspect of the condition known as moveable kidney and to describe certain groups of biliary symptoms which were prominent. The cases of moveable kidney occurred chiefly in women, and statistics were given from the writings of Glénard, Landau, Mathieu, and others to show that from 20 to 28 per cent. of all dyspeptic women possessed a moveable kidney. The causes, diagnosis, and symptoms were then narrated, and among the difficulties that occurred in the recognition of the condition the variability of position and

the simulation of an enlarged gall-bladder, of Riedel's lobe (the floating lobe) of the liver, and of certain renal appendicular conditions were cited. The mobility occurred in an enormous proportion of the cases where the moveable kidney was on the right side. The symptoms of moveable kidney were subjective and visceral. Among the latter class the left kidney was more prone to produce gastric than hepatic symptoms. Hepatic conditions occurred in cases of moveable kidney of the right side. They were defined in three groups: (1) general symptoms of severe biliousness; (2) attacks of colic simulating true biliary colic from the passage of gall-stones, and probably identical with Diett's crises; and (3) attacks of jaundice, three cases reported by MacLagan being quoted. The cause of these hepatic disturbances was next discussed and it was suggested that the symptoms might be due either to pressure on the duodenum or common bile-duct, or to traction on the middle portion of the duodenum, or to reflex irritation of the pneumogastric nerve, the two latter being considered the most probable causes. Dr. Habershon divided cases of hepatic symptoms into three classes from the point of view of their symptomatology: (1) cases of uncomplicated ptosis of the right kidney; (2) cases in which the renal condition was accompanied by a coincident ptosis of the liver; and (3) cases in which the renal ptosis was part of a general enteroptosis. In the slighter degrees of ptosis of the right kidney the hepatic symptoms were often paramount and the following classes of symptoms should lead to the suspicion of moveable kidney. 1. The intractability of the hepatic condition which did not yield to ordinary methods of treatment. 2. The fact that the symptoms were produced or aggravated by shaking or exertion in any form, this being entirely contrary to the experience with regard to an ordinary biliousness, not due to ptosis of the kidney. Eight cases were reported to illustrate the various forms of hepatic symptoms and the relief afforded by replacing the kidney in position.—Mr. R. CLEMENT LUCAS said that the symptoms referred to were those which were usually associated with moveable kidney. He did not think that much good resulted from the use of a belt, and he mentioned the case of an athletic young man who suffered from very severe attacks of what was at first thought to be gall-stone colic. A moveable kidney was found and this condition was treated at first by an abdominal belt. The symptoms, however, only became exaggerated. The kidney was then fixed and the patient was completely relieved. In some cases gall-stones and moveable kidney might be associated. He considered that the relation of the kidney to the duodenum was much more likely to be the cause of the hepatic pain than was any referred pain through the branches of the pneumogastric nerve.—Dr. T. J. MACLAGAN said that there were many cases of moveable kidney which gave rise to no symptoms and that in these cases there should be no interference. Moveable kidney was almost always situated on the right side, and if the left kidney was moveable it seldom gave rise to any symptoms. The hepatic symptoms, he believed, were due to the impinging of the right kidney against the liver. He considered that belts were of little service, but that rest was often most beneficial, especially in thin females, although it had recently been stated that it was of little value.—Dr. HABERSHON replied.

Dr. T. STACEY WILSON read a paper on the Theory of Compensation in Incompetence and Stenosis of the Mitral Valve, and he formulated his views in the following propositions. *In mitral incompetence.*—Proposition 1.—The process of compensation necessitated dilatation of the cavity of the left ventricle as well as hypertrophy of its walls and the amount of dilatation in the compensated heart was directly proportional to the amount of blood which regurgitated into the auricle at each beat of the heart. As mitral incompetence involved the leakage back into the auricle of a certain part of the contents of the ventricle at each beat of the heart it therefore followed that in order to compensate for this leakage and to allow of a normal amount being thrown into the aorta at each beat the ventricle must enlarge so as to hold both the normal amount and that which would escape back into the auricle, and it must thicken its walls so as to be able to move this additional volume of blood. The theory of the enlargement of the ventricular cavity was, he said, as follows. On the first occurrence of regurgitation through the mitral valve a progressive over-distension of the auricle would theoretically result from the leakage of blood back into that chamber. As soon, however, as the size of the auricle

exceeded that of the ventricle the latter would during its expansion be drawing towards itself more blood than it could hold, and the momentum of the blood which could not find entrance would tend to dilate the cavity of the ventricle. In that way the ventricle would be dilated by its own aspiratory force until its size was comparable to that of the auricle. That would not occur until the ventricle was large enough to hold the full amount of the leakage in addition to its normal contents. Proposition 2.—The dilatation and hypertrophy which could compensate for the defective working of the left ventricle during systole would, according to this theory, also relieve the auricle from embarrassment during diastole by ensuring the proper filling of the ventricle. For since the enlarged ventricle was able to accommodate all the regurgitated blood in addition to its normal contents it followed that it would be as easy for the abnormal amount of blood to enter the abnormally large ventricle as for the normal amount to enter the normal ventricle. Also the increased muscularity of the enlarged ventricle would ensure the slight addition to the aspiratory force which was required to draw the larger amount into the ventricle. Proposition 3.—Therefore, by the time the expansion of the ventricle had ceased the auricle would have been relieved of all the regurgitated blood and only the normal amount would remain to be dealt with by it. Proposition 4.—Therefore, in fully-compensated mitral regurgitation no extra work would be thrown upon the left auricle, and there would be no embarrassment of the pulmonary circulation and no accentuation of the pulmonary second sound. Proposition 5.—Neither would there be any dilatation of the left auricle unless the regurgitation were extreme. Since the systole of the auricle and of the ventricle together occupied one-half of the cardiac cycle, it followed that only one-half of the full volume of blood would normally enter the auricle during that portion of the cycle. Therefore, there would be room in the auricle during the ventricular systole for any amount of regurgitated blood up to one-half of the total quantity put into circulation at each beat. If, on the other hand, the amount of regurgitation were to exceed one-half of the normal output of the ventricle there might be dilatation of the auricle, even when compensation was fully established. Proposition 6.—According to this theory of compensation there ought to be a slight increase in the loudness of the aortic part of the second sound, because the greater expansile force of the hypertrophied and dilated ventricle would induce a more powerful recoil of the blood in the aorta and would result in a more powerful closing and stretching of the aortic valves than in the case of the normally-acting ventricle. *In mitral stenosis.*—According to this theory the left ventricle increased its aspiratory power in order to facilitate the entry of blood through the narrowed orifice and so established compensation. This was brought about as follows. Proposition 7.—In mitral stenosis the left ventricle contracted with greater force than normal in order that the rebound, both muscular and elastic, might be correspondingly increased. An evidence of that was the increased loudness of the first sound which occurred in mitral stenosis. Temporary embarrassment of the circulation was accompanied by an increase, often excessive, in the loudness of the first sound, which lessened again as the circulation improved. This increase in the force of the ventricular contraction was also suggested by the occurrence of the hypertrophy of the left ventricle which was not infrequently noticed in mitral stenosis. Proposition 8.—The left ventricle altered its beat. Its contraction terminated with greater suddenness and force than normal. This concentration of ventricular effort at the termination of the systole had the effect of further increasing the force of the ventricular recoil which immediately followed the systole, lasting as it did only one-tenth of a second. This was the explanation of the sharp and loud end of the first sound which was so characteristic of mitral stenosis. The characteristic cardiograms of mitral stenosis often showed a more sudden recession of the heart from the chest-wall at the end of the systole than in the normally-beating heart. Proposition 9.—As a result of that additional aspiration the auricle could be relieved of much, if not all, of the additional work which the narrowness of the mitral valve entailed. Very frequently an absence of dilatation of the left auricle in mitral stenosis where compensation was perfect at the time of death would be found. Proposition 10.—Therefore, in compensated mitral stenosis if the narrowing were not very excessive no extra work was thrown upon the right

side of the heart and there was no engorgement of the lungs. As evidence of this the pulmonary second sound of normal loudness was found even in cases of severe mitral stenosis. It was found, too, that the accentuation of the pulmonary second sound, which was characteristic of failing compensation, gradually lessened as compensation improved. No clinical evidences of pulmonary congestion or engorgement might be found even in severe cases of mitral stenosis. Proposition 11—Some increase in the loudness of the aortic second sound, apart from that due to increased arterial pressure, might also be expected because of the increased ventricular aspiration, as suggested in the sixth proposition.—Dr. PERCY KIDD said that the paper was one which it was difficult to discuss without careful consideration.—Dr. F. W. F. ROSS said that Professor Rutherford had been one of the earliest teachers of the aspirating theory of the action of the heart. He considered that the circular fibres of the heart were principally concerned with propulsion of the blood.—Dr. J. KINGSTON FOWLER said that he did not agree with Dr. Wilson's view as to the causation of the accentuation of the first sound in mitral stenosis. He always believed that in the normal heart the valves floated slowly up as the blood entered the ventricles and shut quietly, whereas in the heart with mitral stenosis the valves were thickened and instead of floating slowly up were brought sharply together. The margins of the mitral valve could often be shown to be faceted.

## OPHTHALMOLOGICAL SOCIETY.

### *Exhibition of Cases and Specimens.*

A CLINICAL meeting of this society was held on Dec. 12th, Dr. DAVID LITTLE, the President, being in the chair.

Mr. H. WORK DOBB showed a peculiar New Growth in the Orbit. The patient was a woman, aged 39 years, who was seen in October, 1901, with the history that 11 years ago she had a small growth of the upper lid which in four years had attained to the size of a pea. This was then removed. Two years later a lump appeared and this broke down and healed several times and had attained to the size of a filbert, being situated at the outer side of the orbit. It was adherent to the bone. The eye was pushed to the nasal side and there was an enlarged gland in front of the ear. The whole contents of the orbit were removed and the bone to which the growth was adherent was scraped. The lacrymal gland was normal. The pathologist's report stated that it was an unusual form of carcinoma allied to rodent ulcer. As much difference of opinion was expressed on the sections the growth was referred to a pathological committee.

Mr. HENRY E. JULER showed the following cases: (1) A Congenital Case of Retinal Pigmentation situated towards the Periphery of the Fundus; (2) Peculiar Macular Changes due to Choroido-retinitis; and (3) a case of Congenital Aniridia. In this latter case the mother and daughter were affected. The mother came to Mr. Juler stating that her sight had always been defective and when seen one eye was quite blind from glaucoma. After removal it was found on dissection that there was a ring of iris at the extreme periphery which had caused blocking of the angle. The lens was partially opaque. The daughter had come under the care of Dr. R. D. Batten also suffering from glaucoma, and for this he had performed sclerotomy, but it was not successful. He thought it was contrary to what one would expect that an eye without an iris should have glaucoma.—Mr. C. DEVEREUX MARSHALL stated that he had seen several cases of this sort and he never remembered seeing one which did not have glaucoma. This was due to the fact that the stump of iris which was always found present was sufficient to block the angle, and this narrow ring was quite sufficient to produce the disease.—Mr. E. TREACHER COLLINS had examined several cases and had shown that they were specially liable to chronic glaucoma.

Mr. TREACHER COLLINS showed a child with Congenital Thickenings of the Conjunctiva, Opacities of the Cornea, and a Notch in the Left Lower Lid in the Vicinity of the Outer Canthus.

Mr. G. BROOKSBANK JAMES showed three case of Infantile Tabes due to Congenital Syphilis. They were all members of the same family and showed Argyll-Robertson pupils and other symptoms of tabes. There was, however, no atrophy of the discs and the fields were normal. He also showed a

case of Occlusion of the Four Lacrymal Puncta, probably congenital. There was epiphora with dacryocystitis, and for this he had opened one of the occluded lower puncta.

Mr. J. B. LAWFORD showed an unusual case of Choroido-retinitis in a subject of hereditary syphilis.

Mr. G. W. ROLL showed a case of Localised Fundus Changes, probably of traumatic origin. The eye was injured in May last by being struck with a piece of iron. Two months later definite fundus changes were present. A foreign body was localised in, or just in front of, the sclerotic. There was seen to be a patch of atrophy close above the macula with pigmentary changes around it. He thought the foreign body, which was three millimetres long, had entered through the cornea, iris, and suspensory ligament, as the lens was clear.—Mr. A. W. ORMOND mentioned a similar case he had had in which after 10 days no wound was visible, although it was easily seen immediately after the injury.—Mr. R. W. DOYNE said that there was a black mark at the back of the lens which possibly was a scar.—Mr. W. LANG mentioned a similar case which he had watched for two years without deterioration of vision, and in the present case as everything was quiet he should be inclined to leave it alone.

Mr. J. H. FISHER showed a case of Mooren's Ulcer on the Cornea.

Mr. L. V. CARGILL showed a woman, aged 22 years, whose Sight had been Gradually Failing for about a year. The family history was good. Two years ago she suffered much from headache, and when first seen she was very anæmic, but an examination of the blood and urine showed nothing abnormal. The vision was  $\frac{6}{60}$  and J. 14. The changes consisted of numerous greyish-yellow spots on the choroid. There were no vitreous opacities and the vessels of the fundus showed nothing but perhaps slight dilatation.

Mr. N. BISHOP HARMAN showed a patient with a Badly Developed Eye with Ciliary Processes adherent to the Anterior Surface of a Shrunken Cataractous Lens. This was congenital.—Mr. FISHER said that about three years ago he had seen an almost identical case.

Mr. HARMAN also showed a simple and efficient Portable Refractometer.

## EDINBURGH OBSTETRICAL SOCIETY.

### *Spontaneous Rupture of an apparently Normal Uterus.—The Separation of the Placenta.*

A MEETING of this society was held on Dec. 11th, Dr. JAMES RITCHIE, the President, being in the chair.

Dr. R. MILNE MURRAY read a paper on a case of Spontaneous Rupture of an apparently Normal Uterus at the commencement of labour. After giving a description of the usual situation and various causes of rupture of the uterus he said that spontaneous rupture might occur in certain abnormal conditions of the uterus, such as the bicornuous uterus, the myomatous uterus, or in a uterus which had previously been the subject of a Cæsarean operation. Krukenberg had collected 13 instances of the last cause, and Rose and Mundé had recorded a case in which the uterus ruptured spontaneously in four successive pregnancies. Lastly, there was a very small number of cases on record in which rupture had occurred at the beginning of labour in a uterus of normal conformation and in which there was no gross complication. Such cases had been recorded by Ingersley, Hofmeier, and Professor A. R. Simpson. In the two first nothing abnormal in the uterus could be found, and the histological examination revealed nothing which could account for the accident. In Simpson's case the muscular fibres showed signs of fatty degeneration in a marked degree. To this group the present case belonged. The woman, aged 27 years, was pregnant with her fifth child. Her pains began about 11.30 P.M. and at 2.30 A.M. she sent for a medical man, to whom she complained of severe pain, especially at a spot midway between the umbilicus and the left anterior superior iliac spine. He could not hear the foetal heart and he noticed the tenseness of the tumour and its marked deflection to the left side. There seemed to be no contraction sufficient to account for the pain complained of. On vaginal examination there was no sign of any presenting part; the finger could not be passed through the os and the cervix was not taken up. On further examination the foetal parts could be felt at the upper part of the tumour with unusual distinctness; and it was thought on consultation to be most likely a case of extra-uterine gestation. When

Dr. Murray saw the patient she presented the appearance of one in a state of profound collapse. On vaginal examination under chloroform the finger, passed through the os, found the cervix only partially taken up; the lower uterine segment was empty and in the left side a rent in the wall could be felt through which the finger passed into the abdominal cavity. Abdominal section was performed and the foetus and placenta were extracted. The rent in the uterus involved the left upper region of the bladder. There was an alarming amount of hæmorrhage going on, both from the tear in the uterus as well as from the proximal end of the torn uterine artery. The uterus was removed and the rent in the bladder was closed by several fine catgut stitches. Owing to the state of the patient the operation was rapidly completed without any peritoneal toilet. The patient did very well till the thirteenth day, when her temperature rose and continued high till the sixteenth day, but fell soon after a copious discharge of pus had escaped from the vagina. The subsequent recovery was uneventful. The formation of pus was attributable to the use of imperfectly sterilised silk ligatures. Dr. Murray could find no cause for the rupture. To the naked eye the uterus presented no abnormality, and microscopically a portion of tissue taken from the end of the rent showed a perfectly normal structure without any suggestion of a fatty change. With regard to the variety of fluids, including meconium, which had escaped into the peritoneum, Dr. Murray thought that if the material was not septic the less the peritoneal cavity was disturbed by attempts at "cleansing" the better. When the matter was septic all means should be taken to prevent its entrance into the cavity; or if it had entered it must be removed at all costs.—Professor SIMPSON, Dr. D. BERRY HART, Dr. F. W. N. HAULTAIN, and Dr. J. HAIG FERGUSON made remarks on the paper.

Dr. J. M. MUNRO KERR (Glasgow) read a paper on the Separation of the Placenta. It had special reference to the information regarding the mechanism observed in cases of conservative Cæsarean section. He referred to eight cases on which he had operated; all the mothers recovered and all the children except one were extracted alive. In six the uterus was opened by the ordinary vertical incision and in two by the fundal incision after the method of Fritsch. In two of the former and in one of the latter cases the placenta was incised and had to be separated in whole or in part before the child was extracted; in the remaining five cases the placenta was situated on the posterior or postero-lateral wall.—Dr. HART, Dr. R. C. BUIST, Dr. MURRAY, Dr. W. FORDYCE, Dr. S. MACVIE, and the PRESIDENT discussed the paper.

Specimens were shown by Dr. HART, Dr. MURRAY, Dr. J. L. LOCKIE, and Dr. HAULTAIN.

**FORFARSHIRE MEDICAL ASSOCIATION.**—A meeting of this society was held on Dec. 5th, Professor D. MacEwan, the President, being in the chair.—Professor L. R. Sutherland sent specimens for exhibition at the meeting: (1) Metastasis in various organs in a case of Deciduoma Malignum; (2) Hæmorrhagic Pericarditis; (3) Papillomatous Ovarian Cyst, with Involvement of the Fallopian Tubes; (4) Tuberculosis of the Tongue; (5) Actinomyces in Human Liver; (6) Cancer of Colon, Perforation of Gut by a Fish-bone; (7) "Rachitic Rosary" in Rickets; (8) Aortic and Mitral Lesion in an infant, aged four days; (9) Superficial Gastric Erosion—Fatal Hæmorrhage; (10) Extreme Duodenal Stenosis from cicatrization of the ulcer; and (11) Recent Corpus Luteum and several specimens showing types of disease in animals.—Professor J. A. C. Kynoch read a paper on six cases of Abdominal Section for Pelvic Affections presenting points of interest. 1. A case of Repeated Ectopic Pregnancy in the same patient. 2. Repeated Ovariectomy. The first operation was complicated with pregnancy at the fourth month. 3. Repeated Ovariectomy within two years. 4. Repeated Ovariectomy; the first operation was complicated with pleural effusion. 5. Ovariectomy, illustrating the condition of pseudo-myxoma of the peritoneum. 6. Ovariectomy complicated with scarlatiniform rash. All recovered after operation.—Dr. J. B. Buist discussed several points brought out in the paper and spoke of the frequency of the scarlatiniform rash after child-birth. He agreed that such a rash after operation was due to toxæmia.—Dr. Halley referred to the frequency of such a rash in children after operation and mentioned two cases of

his own in which the rash appeared after the operation.—Dr. Whyte referred to the occurrence of a similar rash in some patients after treatment with opium.—The President spoke in favour of leaving the other ovary in ovariectomies if it appeared healthy, and said that he considered the rash which occurred in the puerperium was due to septic absorption.—Dr. Halley read a paper on the Surgical Treatment of Sciatica; in it he restricted himself to nerve-stretching. He referred briefly to its first introduction into this country and said that he did not consider it was now done often enough in cases of sciatica, giving some hospital statistics to support his view. He quoted the views of various authors on the effect and results of nerve-stretching. He considered that it was a very effectual form of counter irritation and pointed out the advisability of traction on proximal and distal ends of the nerve and of separating the adhesions as far as possible. Bloodless nerve-stretching was considered harmful without an anæsthetic. The notes of one case were given in support of this. Notes of six cases of the open method of stretching the sciatic nerve were given, in all of which the pain had been relieved and had remained away in one after it had existed for five years and in another for eight years. In one of the cases paralysis of the extensors of the ankle and peronei had followed and continued for three months but then seemed to be passing off. Dr. Halley concluded by expressing the view that nerve-stretching of the sciatic nerve should be done earlier in cases and if pains did recur nerve-stretching should then be performed on the branches.—Professor Stalker spoke in support of nerve-stretching in certain cases of sciatica. He considered it the most effectual form of counter irritation for so deep a structure as the sciatic nerve.—Dr. Foggie spoke of a case in which the adhesions had been excised in addition to nerve-stretching with most beneficial results.—Dr. G. W. Miller also spoke.—The President mentioned cases of improvement after acupuncture, and agreed that nerve-stretching should be adopted earlier in cases where other methods were found to be futile.

**LIVERPOOL MEDICAL INSTITUTION.**—The second meeting of the session of the pathological and microscopical section of this society was held on Dec. 12th, Dr. J. Hill Abram being in the chair.—Mr. F. C. Larkin showed a young man exhibiting the symptoms of Nasal Hydrorrhœa (cerebro-spinal rhinorrhœa). 24 days previously he had fallen 15 feet, striking his forehead first. Immediately after the fall there were slight bleeding from the nose and symptoms of concussion but never complete loss of consciousness. The hydrorrhœa was first observed when he began to get about, three weeks after the injury.—Mr. Chauncy Puzey and Dr. W. B. Warrington showed specimens of Multiple Sarcoma from a young man. In addition to a large axillary tumour there were secondary deposits in the kidneys, the mesenteric glands, and the pancreas. The fundus of the stomach was involved in a mass of about the size of the closed fist which had ulcerated into the viscus. Microscopically the growth was a lympho-sarcoma, some of the cells of which resembled giant cells, being large and multinuclear.—Mr. Douglas Crawford showed (1) a Salivary Calculus which had existed in the left duct of Wharton of a patient for 13 years without giving rise to symptoms until the last five weeks, when the submaxillary gland became swollen; and (2) (a) a Uric Acid Calculus weighing 144 grains removed suprapubically from a boy aged seven years, and (b) Three Calculi weighing 202 grains removed by the same route and from the same boy 18 months later.—Dr. R. J. M. Buchanan exhibited specimens of Pulmonary Calculi which had been expelled during paroxysms of coughing.—Mr. Rushton Parker showed the kidney of a female which he had removed by nephrectomy in the fifth month of pregnancy. On section the organ was plentifully studded with yellow nodules aggregated chiefly in the cortex, and evidently pyæmic. The patient aborted during the next two days and the placenta was removed under chloroform by Dr. T. B. Grimsdale. She continued in an infective state and died on the eleventh day. The foetus was macerating. At the necropsy the spleen, the liver, and the remaining kidney were found to be the seat of softening and cloudy swelling. There were a few chronic ulcers in the large intestine covered with adherent bile-stained lymph, but no clue could be observed, unless that were one, as to the pathological sequence of events or as to the cause of the infection of the right kidney. The upper part of its ureter was dilated and thickened, but no

explanation of this could be found.—Mr. E. E. Glynn exhibited specimens of Pneumococcal Meningitis associated with Lobar Pneumonia, and of Focal Necrosis of the Liver in early Typhoid Fever.—Mr. W. Thelwall Thomas exhibited (1) a Globular Piece of Lung, one inch in diameter, which was found floating in an empyema which had followed pneumonia as a sequel to typhoid fever (the patient recovered); and (2) an Ovarian Abscess Wall which had ruptured into the peritoneum, causing acute septic peritonitis. It was removed during operation for the relief of the peritonitis and the patient recovered.—Mr. F. T. Paul showed a recent specimen of Adeno-carcinoma of the Kidney. The specimens were discussed by the Chairman, Dr. Warrington, Mr. Puzey, Mr. Hamilton, and Mr. K. W. Monsarrat.—Sir William Mitchell Banks read a paper entitled "A Brief Résumé of our Present Position in Regard to Mammary Cancer." The paper was illustrated by lantern slides and microscopical and macroscopical specimens, and as it covered a wide field and presented many interesting and important points for discussion a resolution was passed adjourning the discussion to a special meeting for the purpose to be held in January, 1902.

**BRITISH GYNÆCOLOGICAL SOCIETY.**—A meeting of this society was held on Dec. 14th, Mr. J. A. Mansell Moullin, the President, being in the chair.—Mr. E. Stanmore Bishop described, and illustrated by lantern slides, certain Changes Occurring in the Endometrium of Uteri in which Fibro-myomata were present. The appearances seen seemed to justify certain conclusions, which were: (1) that the presence of fibro-myomata had an effect upon the endometrium of affected uteri; (2) that while still intra-mural they produced hyperplasia of the glandular layer; (3) that when sufficiently developed to exert pressure upon the lining membrane they produce disintegration of the deeper glands and of the interglandular substance; and (4) that when the growth was polypoid the endometrium over the polypus and also over the portion of the uterine wall opposed to it became reduced to a single layer of columnar ciliated epithelium which at points or areas of great pressure approximated to the squamous type. He then gave a demonstration, also illustrated by lantern slides and numerous microscopical preparations, of the condition of the arteries in the macroscopically normal tissue of uteri in which fibro-myomata had been found. The specimens showed progressive thickening of the tunica media and the irregular distribution of the hypertrophied coat around the arterial lumen. These appearances, which were seen in whatever direction the artery had been cut across, lent support to the theory propounded by Pilliet, Gottschalk, and other writers, that these tumours were due to hypertrophic changes in the muscular tissue in the walls of certain arteries. Mr. Stanmore Bishop explained upon this hypothesis the tendency of these neoplasms to be multiple, the formation of a capsule around them, the characteristic whorled appearance of their fibres, the increase of growth during pregnancy and corresponding decrease during involution, and the difference in consistence and rapidity of growth of tumours of the cervix and of the fundus. He finally indicated the effect which the acceptance of such a view must have upon their treatment.—Mr. J. H. Targett had examined sections of many uterine fibroids and he thought that there was abundant evidence of thickening of the muscular coat of the vessels and of their fibrous sheaths. After a time the new material became fibroid and almost devoid of nuclei. This degenerative change was very characteristic of uterine myomata and enabled their structure to be easily distinguished from normal uterine tissue. As regarded the endometrium, he had in some cases found hyperplasia especially affecting the stroma, while in others the endometrium had been thinned by distension and its glandular follicles had become disarranged or even obstructed at their mouths, causing retention of secretion and shed epithelium in their acini. He had never met with tubules lined with epithelium in the substance of a fibroid, and therefore did not think that these tumours commonly originated from congenital relics in the uterine walls, as stated by some observers.—Dr. Macnaughton-Jones cited cases to prove that there was strong clinical evidence in support of Mr. Stanmore Bishop's view.—Dr. Macnaughton-Jones demonstrated Some Recent Gynæcological Appliances and showed the following specimens: (1) Malignant (?) Ovarian Tumours with Myomata; (2) Sarcomatous Tumour of the Vagina; and (3) Adnexal Tumour causing Uncontrollable Vomiting. The last was a cyst of the left ovary containing sanguineous fluid.

**WEST LONDON MEDICO-CHIRURGICAL SOCIETY.**—The third meeting of the session (clinical evening) of this society was held on Dec. 6th, Mr. Alfred Cooper, the President, being in the chair.—Mr. C. R. B. Keetley and Dr. Saunders showed a case of Paroxysmal Neuralgia of the Trigeminal Nerve in which pain had been relieved by stretching and the excision of a portion of the two lower divisions of this nerve.—Mr. Keetley showed also a case of an Osteoplastic Resection for Malignant Disease of the Nasal Fossa.—Dr. Taylor showed a case of Congenital Abscess of the Clavicles.—In reply to remarks by Mr. W. McAdam Eccles, Mr. Lloyd, and Mr. Keetley he pointed out that though the sternal epiphysis showed some attempt at development there was no part of the sterno-mastoid attached to it; that the patient showed some signs of congenital syphilis which might be a factor in the production of the deformity; and that although possibly the nether limbs were more frequently the subject of congenital defects arrests of development were more serious and more profound, as a rule, when they occurred in the upper limbs.—Dr. Ball showed, for Dr. P. S. Abraham, a case of Lupus Erythematosus of the Face associated with Lupus Vulgaris of the Palate.—Dr. Chambers showed for Dr. Abraham a case of Nævus Linearis (so-called) affecting the Right Side of the Trunk.—Dr. Saunders showed a case of Pigmentation of the Skin in a boy, aged 13 years, probably Addison's disease. This affection had come on gradually in the last four months. The pigmentation was general, with accentuation over the region of the back of the neck, the axillæ, the groins and genitals, and over the prominent dorsal spines. It was least over the chest and the backs of the upper arms. The mucous membrane of the mouth was affected. The symptoms were debility, anæmia, and heart weakness, with occasional attacks of vomiting and diarrhoea. The boy had improved considerably in general health under treatment, after attention to the digestion, with cod-liver oil and iron, though the pigmentation had somewhat increased.—Dr. Grünbaum drew attention to two methods based on physiological observations which might assist in the diagnosis of early cases of Addison's disease. Langlois found that the ergographic tracings obtained from patients with diseased suprarenal glands were unique, in that the curve produced by joining the apices of the contractions fell very rapidly. This indicated a rapid diminution in power on the part of the muscle, this diminution being much more rapid in Addison's disease than in any wasting disease, such as advanced phthisis. Dr. Grünbaum had had the opportunity of confirming Langlois's observations. The other method was based upon the effects of the administration per os of suprarenal gland. The only cases in which Dr. Grünbaum had been able to measure any increase in blood-pressure were those of patients suffering from Addison's disease, but whether this was diagnostic of the disease he was not at present prepared to say.—At the second meeting of the society held on Nov. 1st Mr. McAdam Eccles read a paper on Some Points in the Pathology of Appendicitis, and a discussion followed.

**SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.**—A meeting of this society was held on Dec. 5th, Dr. C. H. Willey, the President, being in the chair.—Mr. Edward Skinner showed specimens from a case of Melanotic Sarcoma of the Liver.—Dr. D. Burgess read notes of the following cases: (1) A Gastro-Intestinal Form of Renal Calculus; and (2) Pernicious Anæmia.—Dr. S. White exhibited the following specimens:—1. Aneurysm of the Commencement of the Right Common Carotid Artery for which distal ligation of the carotid and subclavian arteries had been unsuccessfully practised, the patient eventually dying from exhaustion incidental to proximal ligation. The case was interesting on account of the absence of aneurysmal pulse, sphygmographic tracings taken from both carotids showing no appreciable differences. The aneurysmal tumour, which was of the size of a turkey's egg, caused no pressure symptoms beyond contraction of the right pupil, and there was entire absence of thrill and bruit. The patient was a retired soldier, aged 40 years, and had had syphilis. 2. Resection of the Transverse Colon and a Portion of the Small Intestine for a rapidly growing Malignant Tumour of the Omentum in a man, aged 24 years. The patient had made an excellent recovery, but as a number of infected mesenteric glands were unavoidably left speedy recurrence was anticipated. 3. An Excised Chronic Ulcer from the Stomach of a man, aged 52 years. The history dated back four years and the patient had become much emaciated and was no longer

able to work. The ulcer was situated at the upper and back part of the stomach near the pyloric end and measured an inch in diameter. It had almost eaten through the stomach walls and was surrounded by extensive adhesions. The patient had made a good recovery. A noteworthy feature in the case was the advent of alarming hæmorrhage after inflation of the stomach for diagnostic purposes, although previously there had been no hæmatemesis. 4. A Resection of Small Intestine for Round-celled Sarcoma that had produced obstruction. The patient was a female, aged 52 years. The operation was followed by death from shock.—Dr. J. Sorley read notes of a Personal Interview which he had had during the summer with M. Crôte, the founder of a comparatively recent method of treating consumption practised in Paris. The method consisted of the transfusion of a specially-prepared solution of formic aldehyde into the tissues of the body by means of a very powerful static machine. The method had at least a certain amount of probability as regarded its efficacy, and some of M. Crôte's principles had been confirmed by independent observers. A needless amount of secrecy, however, surrounded the nature of the formic aldehyde solution, and until this was published in full the method could not but be tainted with a suspicion of quackery. The examination and treatment of patients seemed to be conducted on sufficiently rigid lines, and the statistics were, if true, little short of marvellous. The treatment was in operation in Paris, Bonn, and New York.

GLASGOW SOUTHERN MEDICAL SOCIETY.—A meeting of this society was held on Dec. 12th, Dr. John Stewart, the President, being in the chair.—Professor Ralph Stockman showed a large number of lantern slides illustrative of clinical and therapeutic interest. The serious effects produced by lead poisoning on the various tissues of the body were well depicted. The constant growth of the connective tissue, the degeneration of the muscular fibres, and the hypertrophy of the coats of the blood-vessels as a result of the action of the lead were rapidly surveyed. In the same disease a photograph of the large intestine showed numerous well-marked contractions at different parts of its course; and pulse-tracings were given to illustrate the increase in the blood-pressure. By a series of slides the different stages in the preparation of anti-diphtheritic serum were brought under notice. Charts were thrown on the screen by which at a glance the beneficial effects of the antitoxin on the local throat conditions and on the pulse and respiration could be rapidly recognised. The injurious effects at times resulting from dressings containing weak solutions of carbolic acid were represented. In one case gangrene of the finger necessitating amputation was brought about by a 5 per cent. solution. In the opinion of Professor Stockman this unfortunate result was produced by the acid causing thrombosis of the artery and the absence in the finger of any collateral circulation. Members were reminded of the peculiar susceptibility to drugs in some persons by the exhibition of slides depicting appearances brought by small doses of cocaine, atropine, and iodine. Other photographs of general interest concluded the lantern demonstration and at the close members had the opportunity of viewing diagrams of various diseases and also some microscopical slides.—Professor John Glaister gave an address, accompanied by lantern demonstration, on the Life-history of the Parasites of Malaria.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—The third meeting of the session of this society was held on Dec. 11th, Dr. Barclay J. Baron being in the chair.—Dr. J. Michell Clarke showed the following patients: (1) A case of Lesion of the Pons; (2) a case of Amyotrophic Sclerosis; and (3) a case of Hereditary Cerebellar Ataxy. He also showed a specimen of Perichondritis and Necrosis of the Laryngeal Cartilages.—Dr. E. H. E. Stack, Dr. C. H. Walker, Dr. F. H. Edgeworth, Dr. T. Fisher, and Dr. P. W. Williams discussed the cases.—Dr. J. O. Symes and Dr. Newman Neild showed microscopical specimens of Blood from cases of Malaria.—Mr. J. Paul Bush read a paper (illustrated by diagrams) on a case of Gastro-jejunostomy.—Mr. C. A. Morton, Dr. R. G. P. Lansdown, Dr. J. E. Shaw, Dr. Clarke, and Dr. E. W. H. Groves spoke on the subject.—Mr. A. W. Prichard read notes on a case of Intussusception.—Dr. J. L. Firth and Mr. Bush commented on the case.—Mr. F. H. Rose read a paper on Kélène as a General

Anæsthetic.—Dr. Symes, Dr. Williams, and Mr. H. E. Harris remarked on the paper.

SOUTH-WEST LONDON MEDICAL SOCIETY.—A meeting of this society was held on Dec. 11th, Mr. John Gay, the President, being in the chair.—The President said that he had the pleasure to inform the society that, through the kindness of the governors of the Bolingbroke Hospital and the exertions of Mr. C. R. C. Lyster (the medical superintendent), the hospital was to be the future home of all their meetings. Dr. J. J. M. Dunbar then proposed and Dr. Mackintosh seconded the following motion:—

That the South-West London Medical Society desires hereby to express their grateful appreciation for the kindness and courtesy of the governors of the Bolingbroke Hospital in granting them the use of the premises of the hospital for the purpose of the meetings of the society.

A vote of thanks was also passed to Mr. Lyster, who replied.—Dr. A. E. Giles read a paper entitled, "The Diagnosis of Pelvic Tumours."—Several members discussed the paper and Dr. Giles replied.—A hearty vote of thanks was given to Dr. Giles for the paper.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Dec. 6th, Dr. Thomas C. Meggison, the President, being in the chair.—Dr. James F. Goodhart delivered the Purvis Oration, taking as his subject, "General Practice: an Original Research." After the oration a largely attended conversation was held.—Mr. J. J. Vezey, F.R.M.S., gave a demonstration of X-ray and High-Frequency Apparatus.—The President exhibited lantern slides of Continental Health Resorts.—There were also exhibitions of the following:—Messrs. Krohne and Sesemann, Surgical Instruments; Messrs. Callard and Co., Diabetic Foods; Messrs. Parke, Davis, and Co., Therapeutic Preparations; Messrs. Watson and Co., Scientific Apparatus.

## Reviews and Notices of Books.

*A Practical Guide to the Administration of Anæsthetics.* By R. J. PROBYN-WILLIAMS, M.D. Durh., Senior Anæsthetist and Instructor in Anæsthetics at the London Hospital; Lecturer on Anæsthetics at the London Medical College; Assistant Anæsthetist at the Royal Dental Hospital of London. Illustrated. London: Longmans, Green, and Co. 1901. Pp. 211. Price 4s. 6d.

THE writer of this book has set himself to instruct students and he has performed his task well. It is important that such teaching should be dogmatic and clear; that directions should be at once concise and lucid; and that only essentials should be presented to the learner, although his attention should be directed to the importance of elaboration, to be afterwards undertaken. Dr. Probyn-Williams has, we think, satisfied these desiderata very successfully. After some "general considerations" the reader is introduced to the Difficulties and Dangers of Anæsthesia, this section being followed by chapters on Nitrous Oxide, Ether, Chloroform, and Local Anæsthesia. The general considerations give a very fair account of the preparation for the anæsthesia and of the patient as well as of the course of, induction of, and recovery from, the anæsthesia. In this connexion it may be said that in ordering washing-out of the stomach *before* giving the anæsthetic in cases of operations upon that organ we think a caution might have been added that such a proceeding produces grave and even fatal shock in very asthenic cases. Nor are we in accord with Dr. Probyn-Williams when he says that a "pin-point" pupil often heralds vomiting (p. 21). The treatment of the patient after anæsthesia is admirably given and is the more valuable as this important matter is too commonly neglected. On p. 52 the treatment of syncope is liable to be misunderstood by the inexperienced. Nélaton who introduced inversion as a means of restoring circulation in the vessels of the brain was careful to limit it to cases of true circulatory failure. If the heart is over-distended from pulmonary engorgement inversion

has always been held to be improper treatment, but this does not lessen the value of inversion in appropriate cases. The author rightly insists that respiratory enfeeblement commonly coexists with circulatory depression and points out that artificial respiration, whether accomplished by Wood's method of pulmonary perfusion or by what is more commonly practised in this country—viz., the Silvester-Bain method—will by itself tend to steady and to assist the flow of blood through the lungs and systemic vessels. Inversion at its best is in cases of sudden fainting often unassociated with overdose of the anæsthetic, for in these there is no question of engorgement of the vessels of the lungs, and especially is this the case in the instance of children.

The chapters dealing with General Anæsthesia describe the more usual methods of administering nitrous oxide, alone and mixed with air or oxygen, or ether given alone or in sequence with nitrous oxide or chloroform. The teaching is sound and the student is not confused by a multiplicity of apparatus or of methods. In speaking of the continuous administration of nitrous oxide by Coleman's nasal-cap method it is said that the most suitable cases are those in which little blood is flowing, such, for example, as operations for devitalising several teeth. Dr. Probyn-Williams, while advocating the use of "gas" and "gas" with oxygen in minor surgery, rightly, we think, points out that for operations lasting more than a few minutes such a form of anæsthesia has insuperable objections. Ether may be given to children by an open method, as Dr. Probyn-Williams very properly points out; but it is a question, we think, that lends itself to discussion whether any particular apparatus, as such, alarms a child. It is the ether, the fright caused by the expectation of the "unknown," which really demoralises the little patient, and probably that method which achieves unconsciousness with the greatest rapidity is the one which gives the child the minimum of discomfort. The description of ether anæsthesia is very carefully and well written. *Inter alia* the common error is exposed that this form of narcosis necessarily involves cyanosis—i.e., incomplete respiration. Again, the chapter which details the administration of chloroform is admirable with, perhaps, the one exception that on p. 153 we are told that "struggling must be met by an increased dose of chloroform with a still freer supply of air." Unless this rule is more fully explained it might, we think, lead the youthful chloroformist into the grave error of allowing the patient to inhale chloroform freely while unconscious struggling is going on. The saving clause, "with a still freer supply of air," may easily under such circumstances be neglected or not appreciated as being the most important part of the rule. Dr. Probyn-Williams indicates the dangers of the various "safe" methods which unfortunately are at present vaunted by instrument-makers, the whole essence of which consists in the dangerous substitution of a mechanical for an intelligent administration of chloroform which is at once the safest and most dangerous of all general anæsthetics. The use of Harley's mixture—the A.C.E.—is fully set forth in these pages and the principles which should guide the administrator are given clearly and emphatically. That this mixture ought to be prepared from definite ingredients as insisted upon by Martindale might, we think, be adverted to in subsequent editions. The concluding chapter consists of an account of the various plans in vogue for producing local anæsthesia. The original solutions of Schleich, which contain morphine, are usually, since the publication of the papers of Dr. Braun and Dr. Heinz, replaced by solutions of eucaine  $\beta$ , and probably this method is superior to those both of Reclus and Schleich. As a whole, Dr. Probyn-Williams's book may be accepted as a successful solution of the difficult problem involved in any attempt to marshal the facts of anæsthesia in such a way that the average student can master them and apply them in

practice. The illustrations, although in some instances rather crude, are mostly original and render the descriptions of apparatus more easy of comprehension. The book is of convenient size and well printed and is provided with a useful index.

*Lehrbuch der Allgemeinen und Speciellen Pathologischen Anatomie für Aerzte und Studierende. (Text-book of General and Special Pathology for Practitioners and Students.)* By Dr. ERNST ZIEGLER, Professor of Pathology at the University of Freiburg. Tenth edition. Vol. I. Jena: G. Fischer. 1901. Super royal 8vo. Pp. 810, with 586 illustrations, some in colours. Price 12 marks.

TWENTY years have elapsed since the first appearance of Professor Ziegler's text-book, and the fact of a new edition having been called for on an average every two years throughout this period bears striking testimony to the value placed upon the book by students of pathology. The present edition, says the author, is the result of 22 years' almost unremitting labour, and we can realise how great the work has been when we consider the strides which the subject has made within this period and observe how closely the book has followed each advance in knowledge. The author's object has been to present the more important contributions of the nineteenth century to our knowledge of pathology in such a form as to prove useful both to practitioners and students, and we may say that in this he has been eminently successful. The large size of the volume (we must admit that it looks a trifle ponderous), by which some may be daunted, is due partly to the extent of ground which has to be covered, but mainly to its wealth of illustrations, not to any lack of conciseness in the text, for the author shows remarkable skill in extracting the important from the unimportant and placing it graphically before his readers. Several changes in the ninth edition will be noticed. The first three sections—on External and Internal Causes of Disease, on the Spread of Morbid Processes in the Organism, and on Immunity—have been rewritten and simplified. These chapters form a useful introduction to the rest of the book. From them the student may obtain a bird's-eye view, as it were, of the whole field which is subsequently to be examined in closer detail and he will thus be spared the feeling of helplessness which is frequently felt by the beginner when he approaches the study of so vast a subject as pathology. The author's views on inflammation have undergone no change, while in the matter of the etiology of certain new growths he has been influenced by recent suggestions as to their probably parasitic nature only to a slight extent, the "not caused by infection" of the former edition having been changed to "probably arising spontaneously." Even this concession, we are informed, must not be taken to indicate any doubt in the author's mind as to the correctness of the earlier statement; it is made merely with the view of somewhat toning down its uncompromising dogmatism. The chapters on Parasites, Animal and Vegetable, have been considerably enlarged and closer attention has been paid to this branch of the subject than might perhaps have been looked for in a work on general pathology. Especially is this the case with some of the pathogenic micro-organisms, such as the streptococcus pyogenes, staphylococcus pyogenes aureus, and the tubercle bacillus. However, no one who has read the description of them is likely to quarrel with the author on this account. The illustrations with which the volume is lavishly supplied are excellent, while the coloured ones, particularly in the chapters which we have just mentioned, are really beautiful. To each section is appended a carefully selected list of references to the literature. These lists the student who wishes to widen his knowledge in any particular direction will find very useful and they will be specially appreciated by anyone who has worked his laborious way through the miscellaneous

mass of references given by many text-books. The volume before us shows us a great advance on the eighth edition, from which the latest English edition was made, both in text and illustrations. The former has in many places been much improved by being re-arranged, while the number of the latter has been increased from 458 to 586. The present edition more than maintains the standard reached by its predecessor and in saying this we accord it high praise.

*A Text-book of Pharmacology and Some Allied Sciences.* By TORALD SOLLMANN, M.D., Assistant Professor of Pharmacology and Materia Medica, Western Reserve University, Cleveland, Ohio. London and Philadelphia: W. B. Saunders and Co. 1901. Pp. 894, large 8vo, Illustrated. Price 16s. net.

WE should have thought that there were enough text-books on pharmacology and allied subjects already in the market. Many, if not most, of them are mere compilations and contain little or nothing of the results of original research. Dr. Sollmann does not lay claim to much originality, but we may give him credit for a new arrangement of much old matter. The book before us is a curious mixture of scientific theories and pieces of practical advice. The volume gives evidence of much laborious reference to standard works, and under each heading is to be found a large number of details, interesting enough in themselves it may be, but of no particular service to the practitioner of medicine. The illustrations are well executed, but mostly unnecessary, including as they do pictures of glass measures, burettes, flasks, retorts, and the like, all objects which the student will be familiar with from the first day which he spends in the laboratory. Other illustrations are those of sphygmographic and other curves which seem a little out of place in this book. "The subject of materia medica is a vexatious one in medical teaching from the difficulty of deciding how much matter should be included," writes the author in his preface. "This is still more true of a text-book intended at once for study and for reference. I have aimed to limit the information to that which is likely to be of actual use in prescribing." We do not think that the author has been very successful in this aim, for there are far more details in some places than are in any way necessary or desirable.

A word of praise must be accorded for the careful preparation of the index of contents; it is full of repetitions and cross-references, which make the work of reference simple enough. After the name of each drug are several page-numbers, but only one of these is in bold-faced type, and that one refers to the main mention of each topic. The work is full of chemical and biological experiments and the effects of drugs on frogs and on mammals are frequently mentioned.

Part I. of the volume contains 126 pages and deals with the work of the dispensing chemist. Part II. is devoted to pharmacology, materia medica, and therapeutics, and includes a certain amount of toxicology. To give the intending buyer an idea of the arrangement of material we will refer to a chapter on the "ion" action of soluble salts. The theory of "ion" action is first discussed, then the "ion" groups are dealt with in turn—first, the sodium, potassium, and ammonium groups, then those of the haloid group. Under the heading "The Bromide Ion," for example, there is first a description of the general action of the "ion" itself, then an explanation of "bromism," then follow paragraphs on excretion, therapeutic uses, and pharmaceutical preparations. The author recommends the use of bromine preparations in cases of "over-action of the brain," and the consequent worry and sleeplessness, but states that bromides are of no value for the relief of pain and that they should not be used as hypnotics.

Part III. of the volume contains 42 pages and is devoted to practical exercises in chemical testing, fermentation

experiments, and experiments on frogs and mammals. Between this part and the index are to be found an appendix containing methods of analysing the causes of pharmacological actions and a reference table of drugs, their chemical formulæ, solubility in water and alcohol, and their doses in apothecaries' and metric systems according to the American Pharmacopœia. This last is a useful table for reference. It has been adapted from the United States Dispensatory and Coblentz's "Pharmacy."

Carefully as this work has been prepared, undoubted as is the large amount of information which it contains, we do not feel inclined to recommend it to the practitioner of medicine who may be on the look-out for a really serviceable book on drugs. Too much is attempted, and the book is consequently neither a complete account of therapeutic measures nor yet a work for thorough reference with regard to the chemistry or botany of medicinal agents.

*Report on Sanitary Measures in India in 1899-1900.* Vol. XXXIII. Presented to both Houses of Parliament by command of His Majesty. London: Printed for His Majesty's Stationery Office by Darling and Son, Limited. 1901. Pp. 262. Price 2s. 1d.

INDIA, as everyone knows, is a very big and densely populated country and the official reports that come from it are very numerous and some of them voluminous. It is, therefore, essential that they should be carefully sifted and considerably abridged in this country to fit them for the information of Parliament and of those interested in our great dependency. When we consider all the labour and ability displayed in India and in this country in their production it is lamentable to think of the waste of energy involved, for while some of the reports only concern a few of the Indian official classes, others merit far more and much wider attention than they receive. Those reports which deal with the public health, vital statistics, and the progress of sanitary and medical science in India are from time to time revised, condensed, and edited in the India Office of this country, and the results are published periodically. Under the above title we have the last published report of a series containing a great deal of varied information, drawn up with great analytical skill, and couched in a clear and terse style of English. We have anticipated the publication of some of its contents when reviewing the excellent report of the Sanitary Commissioner with the Government of India for 1899. We need not, therefore, dwell upon such subjects as the health of the European, and native armies, jails, and general population of India, and the diseases which have been prevalent. We shall confine ourselves to a few, and but a few, points of interest.

The report does not deal exclusively with the statistical, sanitary, or epidemiological sides of disease, but whenever required for the explanation or elucidation of a subject it touches upon pathological and bacteriological points also. At page 47, for example, the bearing of Dr. Horton-Smith's Goulstonian Lectures for 1900 and other contributions to the literature of enteric fever on its scientific side is described. Reference is made, in speaking of tropical fevers, to a bacillus coli form of fever, to enteric fever and dysentery, to second attacks and the periods of incubation of enteric fever, and the cause of relapses. At page 143 there is a brief sketch of the progress made in the investigation of Indian fevers and the new field of parasitology which has been opened out, and at page 150 the facts connected with enteric fever and preventive inoculation in India in 1899 are set forth. The remarks on famine and the birth-rate and the physical and social conditions which promote or retard the comparative fecundity of the Indian peoples are summed up and commented upon in an interesting and instructive manner. The section of the report devoted to the consideration of the history of

the chief diseases—cholera, fevers, plague—and the chronicle which is given epitomising recent discoveries and observations, with their bearing on the many still unsolved problems relating to the etiology and epidemiology of these diseases, strikes us as being very well done. Assuming that these reports are drawn up and compiled by some non-medical official at the India Office from the mass of publications and documents sent home by the Indian Government we may fairly credit him with great discrimination in selecting his material and congratulate him on his ability and skill as a *précis* writer.

#### CHRISTMAS BOOKS.

From Messrs. CHATTO AND WINDUS we have received the following books:—1. *Tales of a Dying Race*. By Alfred A. Grace. 1901. Pp. 250. In this volume are related short stories of the Maoris, and many of them first saw the light in the pages of *The Bulletin*, Sydney, New South Wales, in the *New Zealand Triad*, and in the *Dunedin Star*. Many of the stories are prettily narrated, and describe the Maoris in times of peace and war, love and hate. This book will well beguile many an idle half-hour. 2. *Three Men of Mark*. By Sarah Tytler. 1901. Pp. 334. Price 6s. In this volume is told rather an uninteresting story, without much plot, concerning an elderly Scotch spinster and her three brothers—the “three men of mark.” The lady kept house in the quiet home of the Stewarts at Yetts. To this home the more distinguished brothers come on visits. The book, if somewhat monotonous reading, contains a careful description of Scottish home life and interests. 3. *A Sower of Wheat*. By Harold Bindloss. 1901. Pp. 373. Price 6s.—A powerful story, well written, of Canadian life. The hero, Ralph Crosfield, arrives in Canada with only a capital of £100, and after many difficulties becomes the owner of a large property and marries the daughter and heiress of a retired officer. 4. *Told by the Taffrail*. By Sundowner. 1901. Pp. 311. Price 3s. 6d.—We are informed by the author that these stories have been “thrown together” during the course of a journey through the Austral colonies, the Eastern and Pacific seas, and South and Central America. Many of them have appeared already in the daily and weekly press. They are well written, thoroughly interesting, and will probably be widely read. 5. *Only a Nigger*. By Edmund Mitchell. 1901. Pp. 351. Price 6s.—Readers will find this a lively and exciting story with plenty of thrilling incidents and adventures. It is a tale of two friends, one an Englishman, the other a Hindoo, who are respectively in love with two English sisters. For the sake of his friend and to shield the girl he loves from grief the Hindoo at much danger to himself seeks to save his friend's life which is threatened by a secret society of which the latter is a member. The details are well planned and the subsequent adventures prove exciting. The book is neatly and attractively bound and the reader will find much interest from cover to cover.

Messrs. BLACKIE AND SON have forwarded to us the following:—1. *Nonsense! Nonsense!* Written by Walter Jerrold and pictured by Charles Robinson. 1902. Pp. 66. Price 6s.—The book consists of “nonsense rhymes” and suitable illustrations. The rhymes, however, are so dull that no self-respecting child will ask for them to be read to him twice. The pictures are striking and of a fiery “bluggy” hue calculated to delight any number of young Budges and Toddlies. It is true that sometimes a stupid “grown-up” has to gaze at a picture for some moments before he can recognise what the big red blob on the page represents, but then, of course, much must be forgiven to the benighted beings of the nineteenth century. 2. *With Roberts to Pretoria*. By G. A. Henty. 1902. Pp. 384, 12 illustrations. Price 6s.—The hero of this story, an English lad who went to South Africa shortly before the outbreak of war in order to make his fortune, joins

a colonial regiment and early proves himself to be an exceptionally clever scout. He takes part in the series of battles that end in the disaster at Magersfontein, is captured and imprisoned at Pretoria, but escapes in time to fight at Paardeberg and to march with the victorious army to Bloemfontein. While the troops are delayed at this place he rides with Colonel Mahon's column to the relief of Mafeking and accomplishes the return journey with such dispatch as to be able to join in the triumphant advance to Pretoria. The tale is well told and will delight boy readers. 3. *Carbineer and Scout*. By E. Harcourt Burrage. Pp. 240. Price 2s. 6d.—This is one of the many story-books inspired by the struggle in South Africa. Hugh Dunstan and Cyril Johnstone are good examples of their class—i.e., the youthful hero. Although they have a large share of luck they do not perform impossible feats after the manner of Jack Harkaway.

## Looking Back.

FROM

THE LANCET, SUNDAY, DEC. 21, 1903.

COPENHAGEN, Nov. 18.

Dr. HERBOLDT, of this place, has just published an account of an extraordinary pathological case, which is attested by thirty-four physicians. A young Jewess, of delicate constitution had enjoyed a good state of health up to the age of fourteen years. At this time she began to suffer excruciating pains, which continued for eighteen months, and in the course of this period there were extracted from different parts of her body, at intervals of several days, weeks, and months, 273 needles! Some time after about a 100 more came out from a tumour in the shoulder which was attended with violent pain, and symptoms which threatened her life. They were for the most part sewing needles, but broken, without heads or points, and almost all of them black and rusty. Three pins were found among them, which were still bright, and one of the kind commonly used for the hair. In his statement, the doctor has described with precision the parts of the body from which they were extracted, but he has not offered any conjecture as to the manner in which they could have entered the body of this young person. He promises another paper on the subject, in which we trust he will satisfy the curiosity of the public.—*Journal des Debats*  
*Credat Judeus Apella!!!*

#### ARMY SURGEONS, AND ASSISTANT SURGEONS.

NOTICE has been given to the army surgeons, and assistant surgeons, on half-pay, that their services are likely to be soon required. The new levy is to be raised by beat of drum; and orders have been issued, with a view to the expeditious raising of the men, for the officers employed to repair to those parts of the kingdom, in which they may be supposed to possess the most influence.—*Courier*.

#### ST. THOMAS'S AND GUY'S HOSPITALS ANNIVERSARY DINNER.

The Practitioners who have been educated at St. Thomas's and Guy's Hospitals, and the Gentlemen now attending those Institutions, will dine together on Thursday, the 8th of January next, at the Freemason's Tavern, Great Queen-street, Lincoln's Inn-fields.

BENJAMIN TRAVERS, Esq., F.R.S. in the Chair.

Stewards.

Dr. Roots.  
Frederick Tyrrell, Esq.  
John F. South, Esq.  
George Browne, Esq.  
J. A. Gillham, Esq.  
Tobias Brown, Esq.

Dr. Bright.  
Robert Kent, Esq.  
William Gaitskell, Esq.  
S. H. Sterry, Esq.  
John Prior, Esq.  
James Paty, Esq.

Dinner on Table at Six o'clock precisely.—Tickets, one guinea each, to be had, on or before Saturday, the 3d of January, at the Bar of the Tavern; and Laundry's, St. Thomas's-street.

# THE LANCET.

LONDON: SATURDAY, DECEMBER 21, 1901.

## Public-house Reform.

IT is generally admitted that many of the public-houses in this country are neither regulated nor arranged in accordance with the best interests of those who frequent them. During the last few years efforts have been made to secure improvement in this respect by providing inns which are carefully looked after by committees consisting of people whose chief wish and aim it is to change the existing state of things. Prominent amongst those who have been active in this good work are the Bishop of CHESTER, Earl GREY, Major H. J. CRAUFURD (who is chairman of the Committee of Management of the People's Refreshment House Association), and Colonel Sir COLIN SCOTT MONCRIEFF, K.C.M.G. (the chairman of the executive council of the same association). At the present time this company has 19 inns under its management. Of these the first was taken over in the year 1897. It is situated at Sparkford, Somersetshire, and is owned by the Rev. F. S. BENNETT. In the following year inns at Hoar Cross, Burton-on-Trent, and at Tunstall, Wickham Market, belonging respectively to the Hon. Mrs. MEYNELL INGRAM and to the Hon. W. LOWTHER, were added to the list. In the year 1899 three more houses were obtained, in the year 1900 seven, and during the present year six have been taken. From this it is seen that the work of the association has gradually extended, and it has been carried out in parts of the country situated at great distances from one another. The aim of the association has been "to promote the efficient management of public-houses in the interests of temperance." The manager of each inn is paid a fixed salary; the business has proved remunerative, a dividend of 5 per cent. is paid to the shareholders, and the surplus is devoted to public purposes.

A small and purely local enterprise, the Kelty Public-house Society, Limited, has also been most successful. It was registered in May, 1899, under the Industrial and Provident Societies Act (1893) and has a capital of £1138 10s. The society owns one licensed house. By the rules of the society the maximum dividend payable is 5 per cent. The surplus profits for the year 1900 were devoted in part to the support of a local library and in part to the maintenance of a district nurse. Arrangements have also been made for the formation of a bowling-green and a pavilion in the village. The Hill of Beath Tavern may also be quoted as a remarkably successful venture. The company which owns this inn is managed by a committee of miners. The surplus profits realised during the last five years have been spent in lighting the village with electricity, in forming a bowling-green, and in providing an institute with reading-room, billiard-room, and library. The committee of management of the inn believe in early closing. They think that "a public-house is no place

after 9 P.M. for a man who has to put in a good day's work on the morrow." It seems a little hard that no one shall have cakes and ale after 9 P.M. because the committee are so virtuous. Public-houses, it may reasonably be contended, should be for the use of the public and should be compelled to supply good food and drink at all reasonable hours.

The legitimate complaints which respectable members of the public have against the existing condition of things are (1) that it frequently happens that food is not supplied in public-houses; (2) that when it is supplied it is usually bad in quality and excessive in price; and (3) that the drink supplied is often bad and the price excessive. Now, in regard to the question of food, it is a monstrous shame that every licensed house should not supply it at prices which are reasonably low. Most of the railway refreshment rooms are scandalously at fault in this matter. The bad quality of the alcoholic liquors sold in country places is often due to the fact that one brewing firm has a practical monopoly of a whole district and the unfortunate inhabitants are under existing conditions left to its mercy. Practical public-house reformers usually agree that the manager of an inn shall not derive a pecuniary benefit from the sale of intoxicating drinks, but some of them think that they should be allowed to get a commission on the sale of food. Should this payment be taken from the profit of the food it appears, however, that the customer would by no means benefit by such an arrangement. The societies which have been referred to above seem to obtain enormous profits. It is not very evident that it is to the interest of their customers that so large a proportion of the profits should be bestowed on libraries and other extraneous objects. It would possibly be more to the interests of the people chiefly concerned if the profits were reduced by supplying customers at a less extravagant price. This contention does not appear to have the support of the philanthropists who have been the pioneers of a most useful work. We recommend it to their earnest consideration.

We have lately received a report of an association called the Central Public-house Trust, together with a request that we should authorise the secretary to add our name to the list of members. The president of the society is Earl GREY, the Bishop of CHESTER is one of the vice-presidents, and the executive committee consists of the chairman, Major CRAUFURD, and Colonel Sir COLIN MONCRIEFF, Major-General the Hon. HERBERT F. EATON, Mr. W. CECIL HARRIS, the Hon. ARTHUR STANLEY, M.P., and Mr. E. TENNANT. The association has its chief offices at 114 and 116, Victoria-street, Westminster, and a City branch office at 71 and 72, King William-street, London, E.C. The report says that "the Central Public-house Trust Association in its present form will have completed its work when it has laid the foundation of a public-house trust company in every county." The association invites subscriptions and donations. It publishes a balance-sheet which contains the following note: "There are liabilities, the amount of which has not been ascertained, in respect of secretary's salary, further printing, and the publication of the accompanying report and sundry other expenses." We should be glad if the executive committee would supply some information to elucidate this note. Do not the committee know the salary of

their secretary? Do not the committee get an estimate for printing before they give an order for it to be done? Do the committee consider it necessary to have two expensive London offices? And if so on what grounds? The officers of the association are, we firmly believe, thoroughly in earnest and desirous to do good in a matter of the greatest public interest which needs their help, and we think that they will see the importance of the questions to which we draw their attention and that they will admit that a successful business cannot be carried on without ordinary business precautions. The successful ventures which have hitherto been started have, as a rule, if not always, been either under the direct or indirect influence of a benevolent local autocrat or have been managed by men of business who have been fully acquainted with the wants and wishes of the inhabitants of the district in which the work was carried on. Their success has, no doubt, been due to their adaptation to local requirements.

The formation of these associations and their management have given rise to feelings of great anxiety in the minds of some. In a letter which was printed in the *Times* of Nov. 26th Sir EDWARD FRY expresses his regret that many of the trusts pay an interest of 5 per cent. to the shareholders, and he fears that the shares may be held by wealthy men, even "perhaps by wealthy brewers," and such shareholders, he fears, would care nothing for the cause of temperance. He thinks, moreover, that there is a probability "that attempts will be made by enterprising brewers and distillers to push the sale of their goods by bribing the managers of the reformed public-houses by means of a percentage on the sales." It may be inferred from this outspoken expression of misgiving that Sir EDWARD FRY has little faith in the honesty of the managers of trust public-houses and little confidence in the reality of the supervision which will be exercised by the directors of the companies. One point to which Sir EDWARD FRY calls attention must be specially alluded to. He insists that it will be a serious matter if justices of the peace become shareholders of the trust companies, as they would, of course, in that case be disqualified to act as licensing magistrates, and therefore the number of those who keep a watchful eye on the granting of licences will consequently be lessened. This is a fact which should be considered in all its bearings. Sir EDWARD FRY views with anxiety the application of some of the profits of the Hill of Beath Tavern, to which allusion has already been made. The "surplus funds" ought not, in his opinion, to be spent "in the immediate neighbourhood of their place of origin." Indeed, he is quite sarcastic on the matter, and says, "into what good things the people of the Hill of Beath will drink themselves in the future it will be curious to observe." Sir EDWARD FRY entirely agrees with the Bishop of CHESTER and with Earl GREY that the present state of public-houses is open to improvement, but he sees great danger in their proposed method of affecting it. It does not appear to have occurred to any of the distinguished people who desire to reform public-houses that the interests of those who use them should be primarily considered. The chief causes of differences of opinion amongst them usually have regard to the disposal of the large profits derived from the customers.

## Medicine and the Kitchen.

OF the arts which may be reckoned ancillary to that of medicine there is none probably which is so neglected by practitioners of medicine as that of cooking. Most medical men regard the kitchen as beneath their notice and would scout the idea that any special training in its materials and its methods might be of service to their professional powers and usefulness. Such an attitude of mind is as unwarranted as we believe it to be injudicious. Not only are there very many substances which are common to the kitchen and to the dispensary, a knowledge of which, therefore, is justified by their presence in one if it does not indicate an acquaintance with the other, but, moreover, rightly regarded, the kitchen and the cook play almost as important a part in attaining the aims of the medical man as do the druggist and the dispensary. With regard to both the physician is in the position of directing steps that can only be satisfactorily taken by loyal performance on the part of his subordinates. At the present day, when medical education is so largely scientific and theoretical, to an extent which if in some directions highly beneficial is in others certainly detrimental to the practical value of a practitioner's powers, an intimate acquaintance with the contents of a dispensary and the knowledge of how most efficiently to employ their various combinations may be sought in vain among a large proportion of highly educated and skilful medical men. As regards the humbler offices of the kitchen such knowledge is to be found at even wider intervals. Yet it is obviously of the greatest importance that if a physician orders a medicine he should be able to tell that it is duly dispensed. This cannot be unless he could dispense it if necessary himself, and conversely, a man familiar with dispensing will have far wider powers and more ingenuity and will apply drugs with more minute efficiency than one who prescribes without any such intimacy with the materials which he is recommending. A similar argument may certainly be applied to the products of the kitchen. Yet, if a large number of medical men may claim familiarity with drugs and the modes of dispensing them, few, we imagine, will assert an intimacy with the methods of the kitchen, or even to any large extent with materials which are used in it and the daily use of which they may have many times recommended. No medical man would ignore the importance of diet both in health and in disease, and the cook may well be regarded as a chief officer in the service of preventive medicine. It is, no doubt, in the daily provision of wholesome digestible dishes that the main function of the kitchen lies. No medical man nevertheless can afford to neglect its aid when he is reckoning up his therapeutic resources. More particularly to-day when the use of animal extracts in medicine has become so prominent should the importance of the kitchen be duly recognised. We do not hold the belief of an old writer, quoted in Dr. W. T. FERNIE'S "Kitchen Physic," who says that "the practitioner has only to direct such food as may contain the particles that his patient may stand in need of. For example, are the kidneys diseased? Then let him prescribe stews and broths made of ox-deer and sheeps' kidneys. Asthmas require dishes prepared from the lungs of sheep, deer, calves, hart, and lambs. Are

the intestines diseased? Then he should order tripe, boiled, fried, or fricasseed. When this practice has become general we shall be able to remove every disease incident to the human body by the assistance of the cook only." This writer evidently did not underrate the aid of the kitchen. Unfortunately, the art of therapeutics is no such simple affair as this. The recently proven value of the thyroid gland, however, in the treatment of myxœdema, to take only one striking instance, should lead us to take a close interest in the help that substances which may be most suitably prepared in the kitchen are able to afford us in the treatment of disease, and not to regard the kitchen simply as a place from which the provision of healthy food for healthy persons is all that can be desired or obtained.

If only on historical grounds, medical men should be interested in foodstuffs and their preparation. From the early times when the functions of priest and physician were united in the same man, and when votive offerings and therapeutic agents were alike prescribed and dispensed by his hands, the association of the culinary and therapeutic arts has been a close one. There is a fund of interest and of information in the old accounts of the various properties and powers with which writers from the earliest times invested different articles of diet. Thus, PLINY tells us that "CATO thinks that after eating hare sleep is induced, but the common people suppose that after such food the body is more lively and gay for nine days; this may be only an idle rumour, but, still, for so widespread a belief there must be some foundation." Whether there is any true foundation for such a belief or not an investigation into the exact chemical properties of flesh of various animals and into such articles of diet, for instance, as shell-fish, which are known to have peculiar effects upon certain people, would not only be of great interest but might lead to results of great therapeutic value. Such chemical work as this is a most fitting direction in which to turn some of the efforts of clinical laboratories such as are sure in the future to be more and more extensively employed in connexion with all large general hospitals. There are many widespread beliefs and theories with regard to the effects of different foodstuffs in health and disease. Exact knowledge on such points is scanty. We cannot doubt that in attempting to enlarge and to define it, direct or indirect results of importance and utility would be obtained. Why, for instance, are tomatoes in the popular mind so widely associated with the spread of cancer? We have no grounds whatever for believing the idea to have any reasonable foundation. Yet how much do we know of the special constituents of the tomato? Has it any therapeutic properties? Is it, as a matter of fact, particularly prevalent where cancer is especially common? Such questions and their solution are a natural adjunct to intelligent medical interest in the kitchen, and we have mentioned merely the crudest and most obvious of the many problems, therapeutic and pathological, that the kitchen suggests to us if we honour it with our attention.

There is another point of view from which the cook may be brought to the aid of the practical physician. Supposing that experiment were to show that drugs which now are used only in formally prescribed mixtures or pills were capable of

introduction into the more welcome output of the domestic kitchen, how grateful an assistance might we obtain. It is often difficult when a medicine has to be taken frequently and over long periods of time to be sure that the patient does not grow careless or forgetful. If, however, instead of taking his draught before, or his pill after, his daily meals, that draught or that pill were, without altering the taste of the dish and without losing its own efficacy, combined with the patient's dinner instead of preceding or following it, we can imagine a far more certain acceptance on his part, and the physician's orders would be more consistently carried out by connivance on the part of the cook than they are with the coöperation of the chemist. Such a relegation of the dispenser's duties to the hands of the *chef* can only be achieved by familiarity on the part of the medical man with the work of both his subordinates. With the work of one he is, perhaps, fairly cognisant, with that of the other we strongly recommend him to become more intimately acquainted.

## The University of London and Preliminary Scientific Education.

At a meeting of the Senate of the University of London held on Feb. 27th, 1901, the following motion was adopted:—

"That it be referred to the Faculty of Medicine to consider and report to the Senate as to the manner in which it may best carry out the duty stated in the following paragraph of Section 80 of the Statutes of the University, viz.: 'The Senate shall use its best endeavours, whenever practicable, to secure common courses of instruction for internal medical students in the preliminary and intermediate portion of their studies under appointed or recognised teachers at one or more centres.'"

The Faculty of Medicine accordingly appointed a committee to carry out the wish of the Senate. This committee was made up of 31 members representative of all the schools of the University, and as far as possible of all branches of medical study. The chairman was Mr. H. T. BUTLIN and the committee resolved itself into sub-committees the members of which took upon themselves the task of making inquiries in London and elsewhere upon the matter in hand.

On Dec. 13th the report of the committee was laid before the Faculty of Medicine. The report states that the facts collected on behalf of the faculty fully bear out the statement of the Statutory Commissioners, who framed Section 80 of the Statutes, that the present method of teaching causes a serious financial strain on the resources of the medical schools, and that senior teachers of preliminary and intermediate subjects are underpaid. A persistent decline in the numbers of London medical students is noted, and the committee considers that if London is to maintain her position as a leading centre of medical education some material alteration in the conditions of such education is greatly needed. The faculty, therefore, recommends:—

"That the Senate should take steps to secure funds to enable it to establish in the near neighbourhood of the University a school of preliminary and intermediate medical studies."

The faculty has no doubt that the success of such a school will be certain (1) if enough funds are forthcoming to provide ample educational facilities and adequate remuneration for teachers without increasing the cost of education to

the students; (2) if provision is made for teaching all classes of medical students whether preparing for the examinations of the University or of other qualifying bodies; (3) if due provision is made for research; and (4) if provision is made for the instruction of women students in an institution under the direct control of the University. The faculty, however, feels that if any school wishes to retain the teaching of preliminary subjects it should be allowed to do so subject to the control of the Senate. The report includes a tabulated statement of replies received from the medical schools upon the question of what may be termed a "concentration school." Most of the schools are in agreement with the idea of the Senate that there should be common instruction in preliminary subjects as far as regards chemistry, physics, and biology. With regard to the subject of anatomy the general consensus of opinion seems to be that it should continue to be taught at the separate schools attached to the hospitals. To the questions thus opened up we shall have occasion to return in the main, while upon many offshoots of them we have constantly stated our views. It is undoubted that London as a centre for medical education is not increasing in popularity. London should be preëminent as a medical teaching centre by reason, not only of her position as the capital of the empire, but because of her unequalled wealth of clinical material. So far, however, from her position being maintained it is actually being lost. Seventy years ago the London medical man's teaching was considered hardly complete unless he had been to Paris or Vienna, and at about the same date Edinburgh was far ahead of London as a teaching centre. Since then London has made enormous progress, but the progress has begun to show signs of arrest. The London medical student is at a disadvantage in more ways than one: firstly, he cannot obtain a degree upon reasonable terms; and, secondly, the expense of living in or within reasonable distance of London for the term of five years which is now required is very high. The medical schools of the metropolis are feeling the effects of these two causes with the result that the number of students is lessened, while the teachers, especially of the preliminary subjects, do not receive anything like a proportional remuneration for their time and trouble. A "concentration school" would, no doubt, mean increased economy, but would it also mean diminished efficiency? This is the crux of a matter the numerous aspects of which deserve close attention.

### Annotations.

"*Ne quid nimirum.*"

#### THE METROPOLITAN WATER-SUPPLY.

THE *Times* of Dec. 14th, gives a report of a "smoking concert" which was held on the previous evening at the Whitehall Rooms of the Hôtel Métropole in connexion with the sixteenth annual meeting of the metropolitan division of the National Union of Conservative and Constitutional Associations. Mr. Walter Long, M.P., President of the Local Government Board, was present at the meeting and at a "smoking at home" which was held later in the evening. At these festive gatherings the question of the metropolitan water-supply was discussed. It is necessary,

therefore, that we should briefly refer to them. At a business meeting which preceded the "smoking concert" a report was submitted which referred to the last election of members of the London County Council. The fact that it resulted in a large Progressive majority was attributed to the apathy of the electorate and to the misrepresentations of the Progressive party. How far these two explanations tally, it is unnecessary to discuss. Neither explanation agrees with the one which has been clearly expressed in these columns. It may at the present juncture be worth while to recall the fact that just before the election the metropolitan water companies attempted to force on the people of London the adoption of certain regulations in regard to water-fittings. These regulations were of a character which called for, and received, universal condemnation except from those who were financially or sentimentally interested in the water companies. The people of London generally became aware of a fact which had long been known to those who had studied the question—the fact that active "wire-pullers" amongst the Moderate party were more interested in the water companies than they were in the welfare of the people of London. We gladly welcomed this spread of knowledge and its natural result—the complete defeat at the polls of a party which it was evident would not act in the interests of the London water consumers. It cannot be too clearly understood that THE LANCET has not, and does not take, any part in politics or in municipal politics, except in so far as they affect the public health, and in the matter now under consideration whilst we rejoiced at the well-merited defeat of the Moderates on the London water question we did not, and we do not, approve the attitude of the Progressive party with regard to the matter, but, on the contrary, we maintain that the question is one which can only be settled satisfactorily by taking into account the wants and interests of the inhabitants of a much larger district than that which is included in the County of London. At the "smoking at home," to which we have referred, we are glad to see that Mr. Long with respect to this matter took the view which has been consistently advocated in these columns. "A satisfactory settlement of the water question would," he said, "be a great advantage to London as a whole." It cannot, however, be said that he indicated what he understood by a satisfactory settlement, and he appears to have been facetious, or, at any rate, to have excited the laughter of the audience by referring to the state of uncertainty in which the public is still kept as to the provisions of the Bill which the Government is to introduce. According to the *Times* report, Mr. Long said that "he augured very good results to the Bill from the reception with which his proposals had been received so far as they were known, and he gathered that the knowledge upon them was not very accurate." Any knowledge which the public at present has as to the provisions of Mr. Long's Bill is derived from his own statements and from the *précis* of the Bill which was communicated to the *Times*. If these statements are not accurate it is needless to discuss them and useless to dwell on the vague generalities with which Mr. Long instructed or amused his followers. We will therefore allude to one point only to which he referred—a point which may prove of importance to Mr. Long and to the Government of which he is a member. Having assumed that the purchase of the metropolitan water companies' undertakings 'would be a good thing—an assumption, we may again point out, which may be proved to be groundless—Mr. Long is reported to have said that he believed that the provisions of the Bill which he would introduce "would convince Parliament that they were an honest attempt to act justly as between the vendors and the purchasers, although he did not believe either side would regard them as meeting all

their requirements." This curious statement certainly does deserve a moment's consideration. Mr. Long thinks that Parliament will pass his Bill. He also thinks that the metropolitan water consumers will not regard the Bill as meeting all their requirements. In brief, Mr. Long thinks that Parliament will pass a Bill which will not fulfil the requirements of those for whose benefit it is professedly passed. Is it not possible that Mr. Long relies too much on the "apathy" of the people of London?

#### SMALL-POX IN LONDON.

THE returns of small-pox in London since our last issue are as follows. On Saturday, Dec. 14th, there were 29 new cases notified and removed; on Sunday, the 15th, there were 14 new cases; on Monday, the 16th, there were 35 new cases; on Tuesday, the 17th, there were 32 new cases; and on Wednesday, the 18th, there were 21 new cases.

#### THE SITUATION AT THE MACCLESFIELD INFIRMARY.

WE announced last week that matters at Macclesfield Infirmary with reference to the appointment of a female junior house surgeon were at a deadlock. Miss Clarke, the junior house surgeon elected by the governors, refused to resign when the governors desired to fall in with the views of the medical staff; while the medical men refused to withdraw their resignations save under certain provisions. These provisions have now been made public and are as follows: (1) the selection of resident medical officers to be left in the hands of the honorary medical staff; and (2) the services of the present junior house surgeon be dispensed with from Jan. 15th, 1902. A letter has been sent to the governors of the hospital by the medical staff saying that only if these provisions are granted can they withdraw their resignations, but they promise that in the interim they will do all in their power to prevent any patient from suffering from lack of needful medical attendance. The medical staff state that they cannot agree to the continuance of the present arrangement—under which it would seem that they discharge their obligations, in spite of their wishes having been totally disregarded—for any further period, since they believe that such would be prejudicial to the interests of the institution and of the patients. They therefore have requested the governors to understand that they cannot be responsible for the care of patients after Jan. 15th next except under the conditions which they have stated. We do not see how the medical staff could possibly have come to any other conclusion whatever, and we trust that in spite of the industrious misrepresentations of their action which have been circulated they will maintain their attitude. It is, in our opinion, absurd to say that the whole question of the right of women to use in practice the medical degrees and diplomas that they have gained in examination is at question. Miss Clarke, we are informed, has refused to resign because she is standing for a principle, but, as far as we can see, the principle for which she is stated by certain journals to be making a gallant fight is not involved. The question at issue at Macclesfield is whether the medical staff of a public institution, having thoroughly made up their minds that there are circumstances which make it inadvisable to appoint a female resident officer to work under them, should be ordered by the governors to pocket their convictions. We publish in another column a letter from a well-known and highly respected member of the medical profession who dwells a little in detail upon a side of the matter to which we have barely alluded, but it is a side which has been mentioned by the lay papers published in Macclesfield and the neighbourhood. "X" is not the only medical man who could bring forward evidence that it is sometimes inexpedient for resident medical

officers to be of opposite sexes. "Quite apart from the cruelty to a certain class of male patients in a general infirmary that is involved in cutting them off from communication with their own sex during what may be called sexual troubles, there is the question of domestic convenience. Some of those who know the internal organisation of the Macclesfield Infirmary do not consider that it is quite seemly that one of the resident medical officers should be a female. The governors do not seem to mind this, if they have ever debated it, while the medical staff for obvious reasons of delicacy do not allude to the point. But there are supporters of the infirmary who view the matter in this light and therefore agree with the medical staff, even while being as fully in accord with the aspirations of women as the governors and while thoroughly believing that in a suitable sphere the female medical practitioner may be a boon to her generation.

#### THE ROYAL INSTITUTION OF GREAT BRITAIN.

AMONG the Friday evening lecturers at the Royal Institution of Great Britain are Lord Rayleigh who will take for his subject on Jan. 17th "The Interference of Sound"; Mr. H. G. Wells, B.Sc., who will deal on Jan. 24th with "The Discovery of the Future"; Professor A. Croom Brown who will discuss on Jan. 31st "The Ions of Electrolysis"; Professor Arthur Gamgee who will discourse on Feb. 7th on "Physico-Chemical Researches on the Blood-Colouring Matter"; and Professor H. Becquerel who will deliver in French on March 7th a lecture on "Radio-Active Bodies." After Lord Rayleigh's discourse on Jan. 17th the Duke of Northumberland, who is the President, will unveil and present to the Royal Institution on behalf of the subscribers a bust by Mr. Onslow Ford of Sir Frederick Bramwell, Bart., honorary secretary of the institution from 1885 to 1900. On Tuesdays, Jan. 14th, 21st, and 28th, and Feb. 4th, 11th, and 18th, Dr. Allan Macfadyen will lecture on the "Means of Offence and Defence of the Cells in Relation to Immunity," and on Tuesdays, Feb. 25th and March 4th, Mr. William Napier Shaw, F.R.S., will lecture on "The Temperature of the Atmosphere."

#### TYPHOID INFECTION WITHOUT TYPHOID FEVER.

BACTERIOLOGY has shown that the specificity of the infective diseases depends neither on their clinical evolution nor on the lesions produced, but on the pathogenic agent, and has, therefore, singularly modified nosology. Typhoid fever is a striking example. Its well-defined clinical and pathological features appeared to furnish all that was necessary to constitute "a disease." But they have been shown to be but some of the effects produced by a specific organism—Eberth's bacillus—which may infect the whole system may attack a particular tissue or organ either at the time of the fever or even years afterwards, giving rise to the so-called complications and sequelæ. A further step, which the discovery of Widal's reaction has facilitated, is the recognition of the fact that a lesion may be produced by the typhoid bacillus quite independently of any illness such as typhoid fever. Thus Dr. Cushing has recorded a case of cholecystitis in which cholecystotomy was performed and the typhoid bacillus was found in the gall-bladder and in which the blood gave the typhoid reaction,<sup>1</sup> although there was no history of typhoid fever. The gall-bladder appears to be, like Peyer's patches, a site of election of the typhoid bacillus.<sup>2</sup> At the meeting of the Société Médicale des Hôpitaux of Paris on Nov. 29th M. Fernand Bezançon and M. A. Philibert related the following case. A woman, aged 28 years, who had been exposed to much privation, entered hospital on Sept. 11th, 1901. She was

<sup>1</sup> Johns Hopkins Bulletin, May, 1898.

<sup>2</sup> See THE LANCET, July 9th, 1898, p. 96, and June 17th, 1899, p. 1648.

pale, feeble, and emaciated; the temperature was 104° F. There was no diarrhoea, enlarged spleen, tenderness, or gurgling in the iliac fossa, or rose-spots. She complained of headache but had not the typical typhoid face; her appearance rather suggested tuberculosis, but there were no signs of that disease. On the following morning the temperature fell to 100° and the patient felt better. But in the evening the temperature rose to 102·8° and rigors began; they continued during the whole night. Next morning there was a slight remission (102·5°); in the evening the temperature rose to 102·8°. On the 14th the morning and evening temperatures were respectively 103° and 104·3°; on the 15th they were 103·6° and 105°. The temperature chart, in spite of the absence of other symptoms, suggested the diagnosis of typhoid fever, which was confirmed by the diazo-reaction and Widal's test. On the 16th a tender tumour was discovered, which was evidently the distended gall-bladder. On the 17th (the seventh day of the disease) the temperature, instead of maintaining its level, fell to 103°, and on the 18th to 100°. On the 19th a large greenish liquid stool was passed, the temperature fell to 99·3°, and the gall-bladder was smaller and less tender. Recovery followed. This case appears to be an example of typhoid cholecystitis without the ordinary lesions or symptoms of typhoid fever. Cases of lesions due to the typhoid bacillus without typhoid fever have been but rarely observed. The following are some examples. M. Kelsch has recorded a case of hæmorrhagic pleurisy in a tuberculous subject, M. Fernet a case of serous pleurisy, and M. Guinard a case of appendicitis. Intermediate cases have been described. Thus M. Fernet has recorded a case of typhoid meningitis in which during the whole course the symptoms were those of meningitis and in which the intestinal lesions found after death were very slight. Cases of general typhoid infection (typhoid septicæmia) without intestinal lesions have been described by several writers. Finally, the recent researches of Lœsener, Reinlinger, Schneider, and Chantemesse have shown that the typhoid bacillus may be simply a saprophyte and occur in the stools of healthy persons. Thus in the case of the typhoid bacillus, as in that of other microbes, the simple "germ theory of disease"—that the invasion of the organism by the microbe determines the disease—must give place to a more complex conception. Predisposing causes are necessary. According to these causes, according to the state of the viscera, a general typhoid infection without intestinal lesions (typhoid septicæmia) or with intestinal lesions (typhoid fever) or a local typhoid affection results.

#### TREATMENT OF PLAGUE.

WE have received a copy of a report on the treatment of plague with Professor Lustig's serum at the Arthur-road Hospital, Bombay, by Khan Bahadur Dr. W. H. Choksy, special assistant health officer, Bombay Municipality. The pamphlet affords interesting reading. A brief *résumé* is first given of recent researches in bacterio-therapy, and then the principal characteristics of the epidemic of 1900-1901 are detailed. These are stated to be as follows:—(1) Rapid extension of the local infection with multiple contagious buboes; (2) intense and rapid septicæmia; (3) irregular course, prolonged duration, frequent relapses due to re-infection or extension, indolent buboes remaining enlarged for a long time or suppurating very late, and numerous complications; (4) tardy convalescence, or marasmus from secondary infections, or death from plague pyæmia and consequent toxic degenerations of the internal organs; and (5) greater resistance to the action of serum. The results of the serum treatment were not so satisfactory as in previous years. Dr. Choksy ascribes the partial failure to the peculiarities of the epidemic which are mentioned above, especially the marked tendency to re-infection and the large number of

septicæmic cases. Factors had to be contended with which were practically non-existent previously, and he believes that if another epidemic occurred of the same nature the results would be the same, unless, indeed, it were possible so to perfect the serum as to make it effective against general blood infection. From August, 1900, to February, 1901, the serum treatment was conducted on the selection method. As no serum was available in February only five persons were treated with it. During the seven months comprised in the above period 52 patients were treated with the serum, of whom 35 died and 17 recovered. The non-serum cases numbered 162, and 125 of them died and 37 recovered. The mortality-rate in the former was therefore 67·30 per cent., as against 77·16 per cent. in the latter. Dr. Choksy adds that the difference in the mortality-rate between these two sets of cases would have been greater had there been sufficient serum in February to treat all the cases that were deemed suitable for serum treatment. The results in March, April, and May were as follows: out of 104 patients treated with the serum 81 died and 23 recovered, whereas out of 102 not so treated 81 died and 21 recovered. The mortality-rate therefore works out at 77·82 per cent. in the former and 79·42 in the latter. The unsatisfactory results are due to the number of septicæmic cases which presented themselves, for out of 57 such patients treated with the serum only two recovered, whilst out of 76 non-septicæmic cases 33 recovered. It would appear, therefore, that in the latter class of case the serum has yielded good results, whilst if the patient comes under observation in the septicæmic condition he has practically no chance of recovery.

#### THE FIRST ANNUAL MEETING OF THE NORTHUMBERLAND AND NEWCASTLE MEDICAL ASSOCIATION.

IN the month of November last year the Northumberland Medical Association, which had been founded in the previous August, amalgamated with the Newcastle and District Medical Ethical Society. The object of these organisations and the causes that brought them into existence and led to their union under the title of the "Northumberland and Newcastle Medical Association" have been described at some length in THE LANCET.<sup>1</sup> We have now received the first annual report of the new body. The information contained in this document is encouraging from every point of view. Though the association is only a year old it boasts of 171 members, and a considerable number of the younger members of the medical profession who have not yet formally joined it have, at all events, promised not to oppose its objects. Consequently rather more than half of the medical men who practise in the county have already been won over to this medical union. Nor has the work done been merely that of organisation. From close upon 30 different districts applications have been made on behalf of medical men engaged in contract work, and an advance in payment has been obtained in all these cases with but one exception, and in this case the negotiations are still pending. This great success is due to the fact that no action was taken before all the medical men practising in the district had signed an engagement by which they pledged themselves to support the association throughout. But there are two other causes to explain the success achieved. First, the association created an indemnity fund so that any member who suffered in consequence of any action which he had taken at the request and on behalf of the profession would receive compensation. In actual practice there has been but very slight call upon this indemnity fund. The fact of its existence seemed to suffice to secure that unanimity which ensures victory, and thus there were but few victims. The second cause of

<sup>1</sup> See THE LANCET, Feb. 23rd, p. 561, and March 2nd, 1901, p. 665.

success is the voluntary work of the president (Mr. J. Rutherford Morison), the treasurer, and the members of the various committees. Many of these gentlemen have no personal interest whatsoever in the questions at issue; they have no contract work or club practice, and they have only given their assistance because they are actuated by the altruistic conception that each member of the profession, whatever may be his individual position, should take part in all movements that tend to raise the standing and dignity of the profession as a whole. Thus, the organisers have zealously given advice and assistance to medical men who have encountered difficulties in their practice, and in most cases this has prevented contests that were threatening. For such purposes they have attended numerous meetings of workmen, they have received deputations and committees representing various sick funds, they have spoken and argued, discussed and persuaded, and thus finally arrived at friendly agreement. Then there have been much correspondence and what was, perhaps, most difficult and discouraging, much canvassing of medical men themselves. To be obliged to devote a great deal of time and energy to induce medical men to attend to their own interests is certainly irritating, yet that is the main difficulty. Each member of the profession, says the report, should coöperate because the benefits attained by one section are reflected upon the whole. Then the report adds: "It is not too strong a deduction to make from the fact that this association has done so much in so little time that were the whole of the medical profession in the county to join our ranks we could secure practically any desirable reform." Yet close on half the medical practitioners of the county still stand outside the ranks of the union. The Northumberland and Newcastle Medical Association is so ably managed and successfully organised that there is no excuse for the practitioners of the county to withhold their support. All should join and join at once.

#### THE CORTICAL REPRESENTATION OF THE FUNCTIONS OF THE STOMACH.

Dr. Paul Sollier and Dr. Henry Delagenière contribute to the *Revue Neurologique* of Nov. 30th an account of a case of local injury to the brain which appears to throw light on the question of the cortical representation of the stomach. The researches of Openchowski and his pupils and of Bechterew have shown that in animals there are present cortical centres which preside over the functions of the stomach and intestines. In the human brain it has not hitherto been possible to localise the centre for the stomach. Dr. Paul Sollier in the course of a research into the cortical representation of the visceral functions in hysterical subjects located the "stomach centre" in the middle portion of the superior parietal lobule, the principles and methods employed in the study being detailed in a previous article<sup>1</sup> by the same author. The case recorded below now furnishes the anatomical data necessary to corroborate the localisation propounded. It was that of a boy, aged 11 years, who received a wound in the parietal region of the skull from a pickaxe on May 30th, 1900. He lost consciousness and remained helpless and in a comatose state for a week after the accident. Respiration was slow, at the rate of 12 per minute, the pulse was small and accelerated to 108 per minute, and the temperature was elevated. The wound was the seat of a free and abundant suppuration. There was relaxation of the vesical and anal sphincters. An operation was performed on June 7th and after the application of the trephine two or three fragments of bone were removed. An abscess cavity was now seen involving the brain-substance to the depth of 5½ centimetres (2¼ inches), the shape of the cavity being conical with its base at the surface of the hemisphere,

measuring 6 by 4½ centimetres (2½ by 1½ inches). This cavity was drained of its contents, light tampons of sterilised gauze were packed in, and further drainage was secured by means of small tubes. The temperature and pulse fell to normal on the fourth day after the operation and the patient's condition improved for a while. He could swallow with difficulty, and on the sixth day he emerged from the state of coma and seemed to regain consciousness. He could not reply to questions but he swallowed with avidity everything that was given. The next day he uttered a few words demanding food, and devoured greedily what was given. He could now give replies as to his accident but relapsed into a state of slumber from which he from time to time emerged only to ask for more food. He consumed broths, eggs, meat, and all foods and digested them with equal facility. This excessive hunger (bulimia) became more marked during the next few days and to avoid gastric troubles he was now given four regular meals a day. He continued to improve but his voracity persisted. It was noted that marked right hemiplegia was present after the operation. The paralysis was at first flaccid, but eventually contractures of groups of muscles began to develop. Passive movements and regulated exercises were now adopted for the affected limbs and with perseverance a considerable degree of power of movement was regained. The scalp wound was now completely cicatrised. Bulimia still persisted, and this was looked upon by Dr. Sollier as due to irritation of the gastric centre in the parietal lobe from its proximity to the wound which lay just in front of the middle portion of the superior parietal lobule.

#### THE LEECH MEMORIAL FUND.

A MEETING of the subscribers to the Leech Memorial Fund was held on Dec. 11th, at the rooms of the Manchester Literary and Philosophical Society, with Alderman Thompson in the chair. The report of the committee, which was read by the secretary, stated that the sum of £1251 12s. 6d. had been received from 152 subscribers. Of this amount £1000 had been paid to the Owens College on condition that the money should be called the "Dr. Leech Memorial Fund"; that the income and such portion of the capital sum as the council of the college may from time to time think fit, should be applied for the immediate maintenance of the professorship in, and for promoting the study of, *materia medica* and therapeutics in the Owens College; and that the chair should bear the name of Dr. Leech. The money on these conditions has been gratefully accepted by the council of the college with the desire that its best thanks should be conveyed to the subscribers to the fund. Out of the balance remaining a portrait in oils of the late Dr. D. J. Leech has been commissioned for presentation to the council of the Owens College, and it was also proposed, if sufficient funds are available, to have another portrait executed as a bronze medallion to offer to the board of management of the Royal Infirmary, Manchester, to which hospital Dr. Leech was honorary physician for over 20 years. The report was adopted unanimously and the committee was instructed to carry out its proposals and to issue a balance-sheet and final report to all the subscribers when the fund has been closed.

#### THE NEW MEDICAL OFFICER OF HEALTH OF JOHANNESBURG.

JOHANNESBURG, after having, in common with many other towns in South Africa, passed through a period of storm and stress, is now returning to a normal condition. Week by week more stamps are being set up in the mines and civil life is being again entered upon. The latest development is the appointment of a medical officer of health of the town as distinct from the medical officer of the

<sup>1</sup> *Revue Neurologique*, 1900, pp. 101 and 365.

colony, and we learn with great pleasure that the medical man elected to this responsible post is Dr. Charles Porter, the county medical officer of Shropshire. Dr. Porter, who was for some time medical officer of health of Stockport, graduated with honours as M.D. of the Royal University of Ireland in 1889. He received the Diploma in Public Health from the University of Cambridge in 1891 and is a barrister-at-law and a member of Gray's Inn. In Johannesburg he will find plenty of scope for the abilities which he possesses. The salary is to be £2000 per annum, with assurances as to fixity of tenure and other important matters, while he is to be distinctly chief of the health department and independent of the medical officer of health of the Transvaal Colony. The municipality wish him to organise and control the native quarters outside the town, to frame a sanitary code, to improve the public water-supply, and to investigate the prevalence of typhoid fever and pneumonia. We congratulate both Johannesburg and Dr. Porter upon this appointment, and wish him every success in the performance of his arduous duties.

#### THE DISTRIBUTION OF PLAGUE.

A TELEGRAM from the Governor of the Cape of Good Hope received at the Colonial Office on Dec. 12th states that for the week ending Dec. 7th the cases of plague in the Cape Peninsula numbered 0. At Port Elizabeth the cases of plague numbered 1, a native. The deaths from plague were as follows: coloured persons, 1; natives, 1. In all other places the cases of plague were as follows: Europeans, 1; coloured persons, 1. The deaths from plague numbered 0, and there were no cases in persons under naval and military control. At Mossel Bay 2 further cases of plague have occurred during the week, and 2 cases of suspicious disease have occurred at Ladysmith in persons who have recently come from Mossel Bay. As regards the Mauritius, a telegram from the Governor received at the Colonial Office on Dec. 13th states that for the week ending Dec. 12th there were 42 cases of plague, of which 25 were fatal.

#### THE SECOND REPORT ON THE CONCENTRATION CAMPS IN SOUTH AFRICA.

IN THE LANCET of Nov. 23rd, p. 1435, we referred to the first blue-book which was issued dealing with the subject of the concentration camps in South Africa. The mortality in these camps is undoubtedly very high and the disease most responsible for the death-rate is measles. Measles is a disease which is always attended by a very high mortality-rate in young children and is about the only zymotic disease which is unaffected by sanitation. Even in England and Wales the mortality-rate of measles has steadily increased since the 10 years, 1871-1880, whereas the mortality from other zymotics except diphtheria and whooping-cough has markedly decreased. The form of disease prevalent in these camps is of a peculiarly malignant type and, owing to the difficulties in sanitation which always accompany a crowded population other diseases such as pneumonia have had a high rate of mortality. In continuation of this first report we have received a second blue-book, issued on Dec. 14th, dealing mainly with the new policy of breaking up the larger camps into smaller ones. The mortality for October and November remains regrettably high, but the difficulties with which the authorities have to contend are enormous. Stationary camp life is necessarily unhealthy, and when the habits of the refugees are considered it is a wonder that the mortality has not been higher. They are extraordinarily ignorant, and being in the habit on their lonely farms of disposing of every kind of slops and refuse in the immediate vicinity of

their houses they continue this custom in the camps. When the camps were first formed they refused to use latrines and instead used the space around the tents. While this sort of custom has to be contended with it is almost hopeless to expect that even a camp of only 500 persons will show a satisfactory state of matters.

#### PRESENTATION TO PROFESSOR LIVEING.

THERE was a large gathering of subscribers and lady friends in the hall of St. John's College, Cambridge, on Dec. 7th, when a portrait of Professor G. D. Liveing, painted by Sir George Reid, was presented to Professor Liveing as part of a testimonial in recognition of his valuable services to science. A photographic reproduction of the portrait is to be sent to those subscribers who may desire to receive one, and a bronze bust, to be designed by Miss Edith Bateson, will subsequently be placed in the Cambridge Chemical Laboratory. The Master of Trinity, who made the presentation, said that when future students came to ask the history of some of the worthies whose portraits adorned that hall, and in particular that of Professor Liveing, they would be told that it recorded the memory of an almost perfect student life, of the affection of troops of friends, and the grateful pride of that University.

#### THE CONTROL OF SMALL-POX.

PROFESSOR KOCH, in the remarkable address which he delivered before the British Congress on Tuberculosis, raised more than one point of a controversial nature. But there are few epidemiologists who would not be prepared to accept without demur his contention that the experiences of the past has taught us that there is no one method of prevention which is equally applicable to all diseases. We have, for instance, learnt that the best mode of attacking malaria is to devote attention to the mosquitoes which are the active agents in its spread; that cholera and enteric fever may be best controlled by paying attention to our water-supplies; and that with respect to tuberculosis the destruction or disinfection of the infected sputa is, pending the report of the Royal Commission on Tuberculosis, the royal road to success. At present London is much troubled with small-pox, and there may be advantage at this juncture in asking how far small-pox is a disease which lends itself to a prophylaxis of its own. There is in certain quarters a tendency to deal with small-pox as with a disease against which we possess no special prophylactic means, such as vaccination and revaccination—to treat it, in a word, as we might typhus fever or yellow fever, and, in addition, to expend large sums of money on the "quarantining" of contacts, on international notification, and such like. These measures may be very useful auxiliaries, but it appears to us that in regard to small-pox prevention they are forced into too great prominence, whereas the true prophylactic, that of vaccination, tends to be relegated to a somewhat secondary position. If, in addition to the special prophylaxis other expenditure such as is incurred in connexion with disease against which no preventive "vaccine" has been discovered has to be provided for, we are tempted to ask, What is the use of our State-regulated system of vaccination? Those of us who believe that recent and efficient vaccination is a sufficiently certain protection against small-pox, and who are content to take our risk on this understanding, feel inclined to object to expenditure upon subsidiary measures which can most usefully be practised in the case of diseases against which science has, as yet, provided no special prophylaxis. We who have every faith in the protective power of recently-performed vaccination feel that as a matter of personal selfishness it is absolutely immaterial whether or not those around us hold the same faith. And hence we may naturally object to

a sort of double expenditure—i.e., on vaccination and "quarantine." By all means let a sharp look-out be kept upon those who have been exposed to infection, and in special instances even the "quarantining" of contacts may be desirable; but above all, and primarily, let them be vaccinated or revaccinated, as the case may be, and let their clothes and other effects be disinfected by modern methods. If the machinery for obtaining information is incomplete or unsatisfactory let it be improved. Let varicella be notified in order that we may be in a position to ascertain the existence of small-pox cases, and let us insist, by legislative means if necessary, that vaccination, whether by public vaccinators or by private practitioners, shall be efficiently performed. Let us, too, provide medical men with a special knowledge of the manifestations of small-pox to aid the medical practitioner in cases of doubt. Last, but not least, let us place the medical officer of health in a position to enable him to obtain all such information as is necessary for the proper carrying out of his important functions. In this last connexion there is need for increased statutory powers, as is well illustrated in a recent report by Mr. A. E. Harris, the medical officer of health of the borough of Islington. In this instance the occupier of the house in which a case of small-pox had occurred placed every obstacle in the way of the borough officials who endeavoured to ascertain the names and occupations of the inmates of the invaded house. The occupier in question withheld from the sanitary inspector the important fact that her niece was a pupil teacher in a private school, and another inmate of the invaded house refused to divulge the nature and address of the business in which she was employed. Mr. Harris suggests that the withholding of information such as this should be an offence punishable at law, and we quite concur in the view that the matter should be brought to the notice of the Local Government Board, with the object of a clause being inserted in the next Public Health Act to remedy this undesirable state of affairs. There will, too, doubtless be advantage in there being a closer touch between laundries and the health authorities, so that the spread of the disease by these channels may be prevented or controlled. And certainly persons who have been exposed to the risk of infection should be visited at their homes during the incubation period, even daily visits being paid towards the expiration of the 12 days' incubation. But we have grave doubts whether the very small additional advantages which might be thought of as being gained by isolating contacts in "quarantine" establishments would be at all adequate to the trouble and expense which such a measure would entail. Moreover, we know from experience that inspection at the homes of those exposed is often all that is found to be practicable.

#### AN ITALIAN PHYSICIAN ON THE SOUTH AFRICAN WAR.<sup>1</sup>

"How will you be able to write about Spain after you have been there?" asked Heinrich Heine of Théophile Gautier, who was starting for that country. The deadly, if delicate, rebuke administered to the French *feuilletoniste* by the "Aristophanes of Germany" might have been the motto of Professor Ruata in the well-informed and trenchant remonstrance which he has addressed to his compatriots. "Boeritis," it is just to say, has hardly assumed the virulent form in Italy that it has taken in other countries; indeed, it is only of late that she has, among a section at least of her population, allowed herself to be influenced

by the epidemic of calumny which has pervaded continental Europe against England's conduct of the South African campaign. But that section makes up in noise and persistence for what it lacks in knowledge and impartiality, and so the able and accomplished occupant of the chair of *Materia Medica* in the Umbrian School has prescribed an "alterative" in the form of a recapitulation of the facts, which, however unpalatable to the patient, must end in his recovering the healthy tone that he ought never to have lost. Professor Ruata, indeed, is doing for his compatriots what has been done for theirs by MM. Yyes Guyot and Cornély in France, by the "Old Berliner" in Germany, and by MM. Naville and Jallicet in Switzerland: he has assumed with Madame de Staël that if "the judgment of foreigners" is to be really "the verdict of a contemporaneous posterity," that judgment must have the data put fairly and fully before it and must reinforce the "detachment" of the umpire with the "inspiration" of the eye-witness. The result is one of the clearest and most cogent vindications of British policy and British procedure in South Africa yet published—an *opuscule* which must add to the author's already high reputation as a truth-loving, painstaking, and public-spirited investigator.

Mr. George Lenthal Cheate, C.B., F.R.C.S. Eng., has been appointed surgeon to the Italian Hospital, Queen-square, W.C.

## Pharmacological Notes.

### ADRENALIN.

ADRENALIN, the active principle of the suprarenal glands, has been isolated in a pure form by Dr. Jokichi Takamine, who has published an account of his work.<sup>1</sup> This substance has the approximate composition represented by the empirical formula  $C_{10}H_{13}NO_3$ , but its chemistry has not yet been completely worked out by its discoverer. It occurs in light, white, microscopic crystals, has a slightly bitter taste, and leaves a numb feeling on the tongue where it has been applied. In dry form it is perfectly stable. It is soluble with difficulty in cold water but more readily in hot water, forming a slightly alkaline solution. It is easily soluble in acids and in alkali hydroxides, forming salts; such solutions readily oxidise on exposure to air. The physiological properties of adrenalin have been practically tested on dogs by Dr. E. M. Houghton of Detroit, who finds that a fraction of one drop of aqueous solution of adrenalin, or its salt, in the strength of 1 in 50,000, blanches the normal conjunctiva within one minute. It is a strong hæmostatic. The intravenous injection of adrenalin produces a powerful action upon the muscular system in general, but especially upon the muscular walls of the blood-vessels and of the heart, resulting in an enormous rise of blood-pressure. The result of three intravenous injections of one cubic centimetre of the solution of adrenalin chloride, 1 in 100,000, into a dog weighing eight kilogrammes, raised the blood-pressure 30 millimetres of mercury. This and other experiments indicate that adrenalin is over 1000 times stronger than the fresh glands. The therapeutic applications are already numerous. Generally speaking, when locally applied it forms a powerful astringent and hæmostatic; it may be used in various forms of inflammation and it is also a cardiac stimulant. It is said to be non-irritating, non-poisonous, non-cumulative, and without injurious properties. As an antidote it has been used with good results in morphine- and opium-poisoning, also in circulatory failure, in the prevention of collapse in anaesthesia, and in carrying out bloodless operations in the nose, eye, ear, and throat. It has also given good results in some cases of deafness, hay fever, nasal hæmorrhage, and in various forms of heart disease.

### DIGESTIVE FERMENTS IN SURGICAL PRACTICE.

The local application of digestive ferments to dissolve the

<sup>1</sup> Il Conflitto Anglo-Boero. Appunti del Prof. Carlo Ruata dell'Università di Perugia: Tipografia dello Stabilimento S. Lapi, Città di Castello, 1901.

<sup>1</sup> American Journal of Pharmacy, 1901, p. 523.

coagula and putrescent matter found in lesions or the products of morbid changes in the living human organism is not new. Of such ferments that obtained from a South American species of papaw has been used extensively, according to M. J. Wilbert.<sup>2</sup> Preparations from the milky juice of the plant have been recommended to dissolve the false membrane in diphtheria and externally to aid in cleaning out disagreeable sloughing ulcers by dissolving the broken-down granulations and albuminous exudate that offer both shelter and food for colonies of micro-organisms. The latter use is an old one and is borrowed from the practices of savage races—indeed, the native South American practitioners use a paste made up with the juice of the papaw as a dressing for foul ulcers and offensive sores such as occur among the natives in hot climates. Hitherto the difficulty has been experienced that the keeping of fluid preparations of this drug has resulted in the impairment of the active principle. It is suggested with some reason that any solvent capable of attacking and destroying necrotic tissues without injuring the surrounding healthy cells offers advantages over corrosive or poisonous antiseptics or caustic washes or the use of the curette with its attendant pain. The following formula shows the composition of a solution of the ferment pepsin which has been so used for some time and has given satisfaction in the German Hospital, Philadelphia. It is called "physol" (a corruption of the words "physiological solution") and contains the following proportional parts: pepsin (U.S.P.), 50; menthol, eucalyptol, oil of wintergreen, of each 0.5; alcohol, 10; diluted hydrochloric acid, 20; glycerine, 50; and distilled water to make 1000. 50 parts of talc are used to clear the solution by filtration. The product is a clear, light yellow, pleasantly aromatic solution that appears to keep without any appreciable change in its peptonising properties. Pepsin has the advantage over papaw that it is more easily obtainable and is better capable of being kept in solution. Physol is mixed with two or three times its volume of water and applied as a wet dressing; it has given excellent results by removing the broken-down granulations and other septic materials from old chronic ulcers and abscesses, leaving a healthy granulating surface that may be treated as a clean wound in the regular way.

#### IMMUNITY OF HEDGEHOGS TO CANTHARIDES.

Hedgehogs, according to Alexander Ellinger,<sup>3</sup> are immune to the toxic action of cantharides. Horvath has known a hedgehog to eat 30 grammes of live cantharides, containing 10 centigrammes of cantharidin, during 24 hours without suffering the least harm. This is a large dose compared with that which a human being can tolerate; thus, a fifth of a milligramme causes albuminuria in a human adult, whilst two centigrammes constitute a lethal dose. Ellinger finds that the lethal dose for a hedgehog is 10 centigrammes by intravenous injection, and that a dose of two centigrammes has no effect on the animal's kidneys. These organs are capable of eliminating large quantities of cantharidin without causing any organic lesion. The cantharidin so excreted retains, however, its toxic action on other animals. It is interesting to note that the skin of the hedgehog is susceptible to the irritant action of cantharidin.

## THE PLAGUE IN INDIA.

BY ALEX. GRAHAM-SIMPSON.

### II.—THE BOMBAY PLAGUE LABORATORY.<sup>1</sup>

STRANGE as it may seem, while accompanying Lord Sandhurst around the new Plague Laboratory, Bombay, on the day on which it was opened one could not help recalling the words of one of those old songs of the people that depict in verse, as did Bellamy in prose, an ideal future for the world. There, in a place where plague met one at every turn, where the microbe that has claimed such a large proportion of the population of India was actually being manufactured in countless millions, the thought came back of a good time to come, because one grasped the inner meaning of all the vast

quantities of apparatus; because one saw more than the tubes and bottles and cylinders and burners; because one recognised that here science was adding one more to her victories, that another step was being taken towards a great, though perhaps still far distant, millennium. It was with feelings more of reverence than curiosity that one passed through those transformed rooms of the Old Government House and examined the process by which one of the greatest blessings of the century—a preventive of the deadly virulence of plague—was being produced.

#### Cultivation of the Germ.

The first step in securing toxin is to obtain a medium for the cultivation of the germ to be neutralised. This medium is made by acting upon goat's flesh with acids and subsequently heating it under very high pressure at a temperature of 140° C. As a matter of fact, any flesh would answer the purpose, but that of the goat is deemed best where the native of India is concerned because it appeals to fewest of his many religious prejudices. The heating continues for about six hours, when the little black cylindrical pots in which it takes place, and which are fitted with thermometers and pressure registers, give out a black albuminous solution—practically the same as that which would be found in the human stomach after digesting the same material. This liquid is passed through animal charcoal to decolourise it. Mixed with water in the proportion of 3 to 7 it is then twice heated for the purpose of sterilisation and the nutritive medium is ready.

#### Process of Insemination.

In an outhouse is a huge boiler. Into this are run, in a cradle moving on wheels along little rails, numbers of large flasks containing liquid for sterilisation; and the fact that at one time enough fluid is boiled to dose 32,000 people will convey some idea of the extent of the work carried on—a work, it may be added, unequalled in quantity by any laboratory in the world. The medium thus obtained in another room of the institution is sown with bacilli procured from plague patients, this insemination being accomplished by means of a Pasteur *ballon*. From the ball of the vessel two tubes protrude, one (closed at two points by cottonwool) to form a mouthpiece; the other, long and thin, and when not in use closed at the end by fusion. When insemination has to be accomplished the sterilised medium is placed in a large flask retained in a sloping position. A Bunsen burner is applied to the neck, and particularly to that portion of the neck which contains the wadding forming the stopper, in order to prevent any other microbes existing in air being present. At the same time the sealed end of the *ballon* tube is broken and the burner is applied sufficiently long to get rid of any extraneous matter. Next, the purified end is slipped down through the soft stopper of the flask containing the liquid to be treated. The operator, applying his lips to the disengaged tube of the *ballon*, blows. Any germs from his mouth are captured by the cotton wads on the way down, and the pressure which he thus creates in the sphere causes a portion of the plague-infected fluid within to flow down the opposite tube into the flask, which is at once closed and inscribed with particulars as to date and so on. Numbers of these flasks are inseminated together and between the operations the nozzle of the *ballon* is placed in a tube around which steam is continually playing to keep the glass sterile and to save time by avoiding the necessity of hermetically sealing on each occasion. As a very few drops of the infected liquid are necessary for the cultivation the contents of one of these Pasteur arrangements serve for a large number of flasks. Before and after the operation being performed on each set small sample flasks are similarly treated. If these produce a pure culture it may be assumed that the others will do the same.

#### Haffkine's Germ Test.

The next room visited is that in which in days gone by the governors of Bombay held their State banquets. Even now the tables groan with the weight upon them, but it is not the weight of viands. There in the darkness stand rows and rows of flasks in which plague is living and thriving again. A lighted candle held at the opposite side of one of these shows the stalactite growth suspended from the surface, the introduction of a little cocoa-nut oil having aided in the suspension and in keeping the liquid clear. Haffkine discovered this test for the germ after months of close investigation and the discovery is one of the greatest value.

<sup>2</sup> Ibid., p. 535.

<sup>3</sup> Archiv für Experimentelle Pathologie und Pharmakologie, 1901, p. 89.

<sup>1</sup> No. I. was published in THE LANCET of Dec. 14th, 1901, p. 1692.

*A Beautiful Spectacle.*

Plague, as seen in the hospitals, is dreadful, and more dreadful still does it appear as it glazes the eyes of its victims; but, as it grows here in delicate white points, looking whiter against the rich wine colour of the medium, it is beautiful indeed. A shake, and still greater beauty is manifest. The points become disengaged from the surface, roll themselves into thousands of tiny balls, and fall like a miniature snow-storm to the bottom of the flask. For six weeks at intervals the medium is so shaken until at last it is found that no more fresh germs are produced. There is then a solid deposit of living, virulent plague bacilli at the bottom of each vessel. The liquid above is full of their poison and is, in fact, what is known as the toxin.

*Final Sterilisation.*

Away to another room the flasks are taken. There they are placed in a boiler and heated for an hour at 65° C., care being taken to keep the temperature even. When the time is up they are rapidly cooled in troughs specially constructed by Government to the design of the staff. In this way the microbe is killed. To the toxin is now added  $\frac{1}{2}$  per cent. of pure carbolic acid, also sterilised. The liquid is now ready to be syphoned into bottles, a process in which, again, are manifest the wonderful care and exactitude necessary in all that pertains to bacteriological science. Again there is sterilising with the Bunsen burner. A long tube, part glass, part rubber, is inserted in the toxin mixture, and the rubber being used for the performance of a sort of milking operation from the flask the contents are drawn off into heated medicine bottles stoppered with sterilised cotton-wool plugs. These plugs are removed, the necks of the bottles are heated, and the bottles are closed with corks, also sterilised in a solution of 4 per cent. formalin and dipped into boiling paraffin so as to create a wall between the cork and the glass. In the stoppering the cork is only touched with heated forceps. Cork and neck are now covered with carbolised parchment which in turn is fastened on with carbolised string. The whole is dipped again into the boiling oil so that all crevices may be closed and a label with particulars regarding brew and dose is affixed.

*A Wonderful Factory.*

In the packing-room below native women are to be seen deftly arranging these bottles in cases ready for export, and neat boxes full of them, with all details stamped on, are sent to nearly every part of the world, of late particularly to South Africa and Australia.

It is a wonderful factory this, an almost unique concern that sells at a loss that humanity may gain. Pity it is that the natives of India cannot be made to understand its value and that the numbers who go to be inoculated are not more in proportion to the number who year after year are stricken down with the plague. Lord Sandhurst could have known Bombay in no more unhappy times than those of his governorship, but it should be to him a bright remembrance that under his government the discovery of plague prophylactic was made, that he forwarded the research, and that among the many institutions with which he was prominently connected in the Presidency of Bombay he can number the great plague laboratory.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

An ordinary meeting of the Council was held on Dec. 12th, Mr. H. G. HOWSE, the President, being in the chair.

The PRESIDENT reported the death of Sir William MacCormac, Bart., K.C.B., K.C.V.O., Member of the Council, past-President, and past member of the Court of Examiners of the College.

The following vote of condolence was then carried: "The Council hereby record their deep regret at the death of their colleague, Sir William MacCormac, Bart., K.C.B., K.C.V.O., and their very sincere sympathy with Lady MacCormac in the loss she has sustained. The Council desire to express their grateful sense of the many services rendered to the College by Sir William MacCormac and especially to record their appreciative recognition of the dignity and distinction with which he fulfilled the duties of President during his five years of office. For these reasons, as well as for those

personal qualities which won for him so many friends, the Council believe that his loss will be long felt and deeply mourned."

The PRESIDENT stated that the vacancy in the Council occasioned by the death of Sir William MacCormac would be filled up at the annual meeting for the election of members of Council in July, 1902.

The PRESIDENT reported the delivery of the Bradshaw Lecture on Dec. 11th by Mr. T. R. Jessop, the subject of the lecture being, "Personal Experiences in the Surgical Treatment of Certain Diseases." The best thanks of the Council were given to Mr. Jessop for his lecture and he was requested to publish it.

The President was nominated as the representative of the College to attend the Jubilee of Owens College, Manchester, on March 12th and 13th, 1902.

The following motions were passed in reference to the resolutions<sup>1</sup> carried at the annual meeting of Fellows and Members:—

1. That the Council having fully considered the resolution moved by Dr. Thomas Morton, seconded by Mr. Joseph Smith, and carried by 30 votes to 2, are of opinion that it would be most undesirable to re-open the question of the representation of Members on the Council.
2. That the mover and seconder of Resolution No. 2 be informed that the resolution has been placed before the Council.
3. That the mover and seconder of Resolution No. 3 be informed that if the British Medical Association should officially forward a copy of their Bill for the amendment of the Medical Acts, if there be one, the Council will be prepared to give it their earnest consideration.
4. That, as it is essential that the representative of the College on the General Medical Council should be a member of the Council of the College, the Council of the College are of opinion that the election should remain in their hands.

## METROPOLITAN HOSPITAL SUNDAY FUND.

UNDER the Presidency of the Lord Mayor the annual general meeting of the constituents of this Fund was held in the Council Chamber of the Guildhall on Dec. 16th.

The report of the Council for the year ending Oct. 31st, 1901, stated that since the publication of the last report the friends and members of the Hospital Sunday Fund, in common with all the inhabitants of the Empire, had had to mourn and regret the death of their late beloved Sovereign, Queen Victoria, who had been patron of the Fund since its establishment, and that the King had accepted the position of patron. The amount collected during the year was £54,731 18s. 3d., being £2738 4s. 9d. in excess of the amount collected in 1900, and, with the exception of 1895, when the Fund exceeded £60,000, the highest amount yet recorded. The total collected by congregations of various denominations amounted to £36,388 6s. 4d. Prebendary Ridgeway of Christ Church, Lancaster-gate, again headed the list of contributors with £1317; Canon Fleming of St. Michael's, Chester-square, collected £1233; and Prebendary Storrs of St. Peter's, Eaton-square, £652. There was an increase this year of £532 in the collections from congregations and 16 more congregations had collected. Mr. George Herring for the third time had sent his munificent donation of £10,000. Sir Frederick L. Cook, Bart., M.P., had sent a special donation of £4000. Sir Savile Crossley, Bart., had again generously contributed £500 (tenth donation); "A. G. P.," £200; and "Delta" had sent his twenty-third donation of £200.

The LORD MAYOR, in opening the proceedings, said that the constituents of the fund had suffered a heavy loss by the death of the great, good, and noble Queen Victoria, who was its patron from the commencement, and they owed a debt of gratitude to His Majesty for having agreed to become patron of their great work. There was every reason to be thankful for the response made to their appeal for contributions this year. The amount received was very near £55,000, an increase over last year, and with the exception of 1895, when special reasons operated to raise the income to £60,000, it was the highest amount yet recorded. They had again to thank Mr. George Herring for a donation of £10,000, and also Sir Frederick Cook, M.P., for £4000, and Sir Savile Crossley for his tenth donation of £500. These large and noble gifts were given because the donors thoroughly appreciated the fact that the work of the Fund deserved the greatest support and sympathy.

The Rev. C. H. GRUNDY moved the adoption of the report, remarking that those who were most associated with the fund were each year more and more impressed with the business-like way, and with the justice, insight, and enthusiasm with which the fund was conducted.

The Rev. Dr. RIGG, in seconding the motion, trusted that under the care and support of the Lord Mayor the fund would next year take another step upon the past.

A speaker, rising in the body of the council chamber, said

<sup>1</sup> THE LANCET, Nov. 23rd, pp. 1460 and 1461.

that as one who moved about a good deal among the churches he was anxious to know whether the committee were perfectly clear with regard to the allocation of the money. In connexion with the Prince of Wales's Fund a good deal of dissatisfaction had been occasioned in consequence of certain of its funds being granted in support of medical schools. A report was going about among the churches that this fund did the same, and, if proved to be true, it would seriously interfere with the gifts of the congregations next Hospital Sunday. He wished to know whether any of the money of this fund had been diverted from the wards of hospitals for the support of medical schools.

Sir SAVILE CROSSLEY (honorary secretary to the Prince of Wales's Hospital Fund) denied that the funds of the Prince of Wales's Hospital Fund had been given in support of medical schools.

The LORD MAYOR said that the question appeared to be whether the committee were justified, before making certain grants to hospitals, in finding out whether the money would be applied to the maintenance of the hospital proper or the medical schools. His answer was that they had nothing whatever to do with the matter. The money was allocated for the grand whole, and he thought that duty was equally done to their own generation and those who came after them whether the money was used for the relief of afflicted mankind in the wards or in bringing the medical schools up to date.

The report was then adopted.

On the motion of Mr. HAY CURRIE, seconded by Sir SAVILE CROSSLEY, the laws of the constitution were passed. Incidentally Mr. Currie referred to the illness of the secretary of the fund which, he said, they all regretted.

On the motion of the Bishop of BARKING, seconded by Sir BORRODAILE SAVORY, the Council for the year 1901 was re-elected for the year 1902, with the Right Rev. the Bishop of Islington, the Honourable Rupert Guinness, C.M.G., Sir Frank Green, Bart., and Mr. J. T. Scriven to fill vacancies.

Archdeacon SINCLAIR proposed that June 15th should be fixed for Hospital Sunday, 1902, and that the cordial coöperation of all ministers of religion within the metropolitan area should be again invited in the usual way.—Dr. ADLER seconded the proposal, remarking that as next year was the coronation year there was every reason to hope that the collection would be a record one. He trusted that the sum collected would reach nearest to the ideal amount of £100,000.

On the motion of Mr. F. H. NORMAN, seconded by Dr. J. G. GLOVER, a hearty vote of thanks was awarded to the Lord Mayor who, in responding, said he yielded to none in his desire to further the great work of the Metropolitan Hospital Sunday Fund.

## NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

A SPECIAL general meeting of Governors and subscribers was held at noon on Dec. 12th, at the National Hospital for the Paralyzed and Epileptic, Queen-square, Bloomsbury, to consider the Draft Rules for the constitution of the hospital drawn up by the committee appointed by the Governors to make such arrangements as were necessary for dealing with all matters consequential upon, or arising out of the adoption of, the resolution at the special general meeting of the Governors and members of the hospital held on July 6th, 1901, that the report of the Committee of Inquiry be adopted.

The Hon. SYDNEY HOLLAND, having taken the chair said: This meeting is called to reject or accept the proposals of the Reconstruction Committee, the committee appointed in consequence of the decision of Sir Edward Fry's Committee of Inquiry. I ask Mr. Green as chairman of the Reconstruction Committee to move the adoption of the report and I ask him for the purposes of convenience to divide that report into two parts. The first part deals with the reconstitution of the hospital and the second with the pension for Mr. Rawlings.

Mr. MELVILL GREEN: I myself would have suggested, if you had not done so, that the report be received in two parts because of the reasons that you have given. All I have to move now is that the report of the committee of which I have had the honour of being chairman, so far as it relates to the repeal of the rules that now exist and the creation of new ones, be adopted, and that the rules of this hospital be repealed and the new rules adopted accordingly. I am sorry not to be able to stop at this point altogether, but I am afraid it has become necessary to say a little more. The rules carry out in substance the report of the Committee of Inquiry. They do a little more and they do a little less. The committee has taken the opportunity of making a few small alterations in the existing rules on some points not touched upon by the Committee of Inquiry, and I do not think I need say anything about them unless anyone wants me to, as it will waste time to go through details about which we are all agreed. In the same manner

we have done a little less, as we have pointed out in our report. We have pointed out in our report that we advise that the existing by-laws be abolished *en bloc* and that the Board of Management, all the members of which it will be observed must be elected on the coming into force of the new rules, be left to make such by-laws as they may from time to time find to be necessary. We are not able to advise the governors to go quite so far as the Committee of Inquiry recommended in paragraph 106 of their report, which suggested that new by-laws should not be effective until confirmation by a general meeting. By Rule 39 we have provided that new by-laws shall be immediately effective, but that unless they are confirmed by the following annual general meeting they shall be annulled. We vary in that respect and that, I think, is the only point of variation of real consequence. I believe we were unanimous in thinking that it would work with greater convenience than if we had allowed 12 months to elapse before the Board could make a by-law which they saw was useful. I might add that the committee were all of this opinion, that the rules as laid before you now are not only those that will work, but those that under the circumstances in which we find ourselves are the best that can be provided, and I think they are exceedingly good. We have certainly made sure of the representation of the medical staff on this committee. We have certainly made sure that the office of director, which has been at the bottom of all the friction that has arisen, should be abolished (loud cheers), and I should have been content to have been able to stop at this point. But we have all received a circular from the Board of Management addressed to us under the signature of Mr. Russell whom I am glad to see here and who will be able to explain it if I have misunderstood it. I do not know exactly what members of the board may have been present when this circular was passed, or how far it represents the board, it certainly does not represent them all, because Mr. Pearman and Mr. C. F. Campbell, who are part of the committee for which I am speaking, have assented to the rules being carried *en bloc* that are before you in the report, the adoption of which I am now moving. The committee took the precaution after we had finished to send the rules to every member of the board in order that before we asked that this meeting might be called we might learn whether there was anybody who thought the rules were unworkable or were objected to, and until I received the circular from the board I was under the impression that there would be no doubt as to their being carried unanimously. But we have received the circular and I cannot help referring to it. I am sorry to see it because it prevents me from abstaining from referring to the past. It is not my fault, it is Mr. Russell's and those gentlemen who authorised him to sign and send this circular out. This circular has produced a most unfavourable impression on my mind towards the capacity of the Board of Management for managing the affairs of the hospital.

The CHAIRMAN: I am sure, Mr. Green, you will excuse me, but I do not see that it will advance matters a bit to throw mud at the other side, because if you make remarks like that it will lead other people to make remarks, and I really do not see how this meeting is ever to come to a decision or how we are to do any business if we begin that sort of thing. We are here to discuss the rules of the hospital and the advisability of their adoption.

Mr. GREEN: We have had this circular sent to us to influence us today. You will have to hear from my mouth or from some other person's mouth the reasons why it should or should not influence us.

The CHAIRMAN: I am sorry, but I can only give you my ruling.

Mr. GREEN: This circular discloses this, that the persons on whose behalf it was signed are perfectly satisfied with the management of the hospital as it was before these disturbances two years ago. It discloses that perfectly, and that we have seen all along to be the case. It points out to us—if I may paraphrase the circular—and seems to me to say this: we the Board tried to maintain the old system. We made every effort to do so until we saw we were beaten. We did not agree and we would not agree to a searching inquiry until we saw we were about to be beaten, and then we withdrew our motion in favour of Mr. Green's amendment for a complete inquiry. Since then much light has been thrown on the reason why the Board struggled so hard that there should not be a searching inquiry.

The CHAIRMAN: I must rule this discussion as really out of order. I think it is a very great pity that you do not adopt my suggestions to deal simply and solely with these rules and not to criticise this circular. There is a very great deal of difference between criticising the circular in the sense of answering it and doing what you are now doing which will necessarily lead to answers from the other side. I cannot rule a man out of order if he gets up to answer you, therefore I do ask you from the chair to keep to the argument and nothing else.

Mr. GREEN: I will endeavour to do that. This circular admits that the two great points that I have mentioned have got to be maintained and then the circular goes on to try and water them both down. The medical staff are to be represented on the board. Very well then. Look at the bottom of page 2 of the circular. There are two suggestions made about the medical staff. One suggestion that we make in the Draft Rule 10 is that every member of the staff shall be at liberty to come into this room and to speak and vote at any meeting of governors. It does not seem to me a very remarkable thing. What does the board's circular say? Oh, no, make a man serve seven years on the staff before you allow him to do that. Cut down the influence of the staff all you can. And then what do they say further, that in the quorum for a general meeting the medical staff shall not count. (A Voice: Why?) Why, indeed! Unless it is to do away with a fair and reasonable position for the staff, and unless it is to carry out the idea of keeping the staff in a sort of inferior position—in fact, looking upon the staff, as was done before, as servants of the institution and nothing more. It seemed to me as if this circular had in its mind the idea of keeping the staff down and making their position almost impossible. The circular goes on to say that the proposed Rule 41 "provides for the appointment of a secretary, a senior house physician, and a lady superintendent, who shall have the sole control of their separate departments under the board. The duties and functions of these three officers must necessarily overlap, and in the absence of some authority to whom instant and effective reference and appeal can be made upon matters of daily and hourly occurrence as to which differences of opinion may arise, confusion must ensue with consequent injury to the interests of the patients and of the institution." In all the years that are passed for seven hours of the day Mr. Rawlings has been on the spot to prevent confusion, but no confusion arose during the other 17 hours. Why should we, then, be afraid of confusion during the 24 hours? It is a

fact that the secretary-director was here only seven hours in the day and these things must surely sometimes arise before 10 in the morning and after five in the evening, and yet we had not heard of the confusion. Now the next sentence is this; it is practically all one: "The board feels strongly that there should be some one person responsible to the board for the daily conduct of affairs at the hospital." What is that but bringing back the secretary-director? That is the very thing that is not to be done. The staff are not to be belittled and the director is not to be brought back, but the two things agreed on must be carried out in their entirety.

Sir JAMES CRICHTON BROWNE, in seconding Mr. Green's motion, said: In expressing a hope that peace and harmony will henceforth prevail in the wards of this hospital I think the spirit of the report of the Committee of Inquiry was eminently conciliatory. In that spirit it was certainly accepted by the medical staff and by the governors who supported the staff. There can be no doubt that the report was favourable to the views taken by the staff. On the adoption of the report of the Committee of Inquiry by the Governors there were no ejaculations of triumph on the part of the medical staff and on the part of those governors who supported them. Indeed, the medical staff and the governors who supported them accepted the report with loyalty and unanimously joined in taking the measures necessary to give effect to the recommendations of that report. I think, Sir, they have a right to expect that the Board of Management will loyally accept the report and will loyally accept the drafted rules for the reconstitution of the hospital proposed by a thoroughly competent committee upon which the Board of Management was fully represented. At any rate, I think they have a right to expect that there shall be no attempt by hints or by suggestions or by amendments of these rules to get behind the report of Sir Edward Fry's committee and render some of its recommendations nugatory. I wish to call your attention to one point in this circular from the Board of Management; they say it is a very serious proposal to divide the work of carrying on the daily administration of the hospital between three independent co-ordinate authorities, those of the secretary, the senior house physician, and the lady superintendent. They say that this arrangement is certain to lead to collision and to difficulties, but they seem to forget that all those three different authorities would have a central authority and would be responsible to the newly-appointed board of management, and they seem to forget that this very same tripartite arrangement has been tried and found to work exceedingly well in many large public hospitals in this country. It seems to me there can be no difficulty whatever in making absolutely distinct and well defined the duties of these different authorities. There would be no necessity for overlapping at all, and we might just as reasonably object to there being different departments in the Government, such as the War Office, the Home Office, the Foreign Office, who all have their centre in the Cabinet, as to object to the three officers having their central authority in the Board of Management. I do not think there can be any difficulty. If there is to be any departure from the proposed rule I hope that Mr. Russell will bear in mind that this is a medical institution in every department of which the medical staff must have paramount influence. If one of these three authorities is to be supreme it should be that of the senior house physician. The policy suggested by these hints thrown out in this circular from the board seems to me to be exactly what Mr. Green has indicated, that is, to pave the way for the introduction of a Hawlings the second into this hospital. Now, if there was one conclusion in Sir Edward Fry's report it was that there should be an end of the autocratic power of the secretary-director. I must say, Sir, I am anxious to avoid any unnecessary friction, as you have most wisely suggested, but I must say that this circular, which I regard with Mr. Green as most unfortunate, does necessitate a little plain speaking. It seems to me an attempt from the way in which it is worded to emphasise and put into prominence everything that was favourable to the Board of Management in Sir Edward Fry's report and to ignore everything else. It echoes the statement in the report no doubt correctly enough that, generally speaking, the hospital was in good order, that the patients were satisfied with their food, treatment, and nursing, and their condition generally. It also emphasises the statement contained in the report that the defects in management to which attention was drawn by the statement of the medical staff were deserving of notice and correction, but they were never sufficient in magnitude and frequency to render the treatment in the hospital otherwise than good as a whole. But, gentlemen, that was not all and I must say that, having read that report of Sir Edward Fry's again, I do regard it as a very serious censure on the Board of Management. I do not think that such a severe censure has ever been made on a hospital committee before, but I must ask you to bear in mind that the report distinctly stated that—

The CHAIRMAN: I do ask you from the chair not to refer to the past. It is not the slightest good. We do not advance one little bit by referring to the bad management of the past or to the bad conduct of anyone. I do ask you on this occasion to fight for peace.

Sir JAMES CRICHTON BROWNE: I assure you I have no desire to fight on the present occasion. I only regret very much that the harmony of the proceedings should have been disturbed by this most unfortunate document. I refer, however, to the main fact in Sir Edward Fry's report and that was the decision arrived at that there had not been proper facilities for intercommunication between the medical staff and the board and their recommendation that two members of that staff should be appointed to the board. That seems to me to be the crucial point. That was the main position on which the Board of Management took their stand, and I am at liberty to say that one of the members of the board distinctly told me that rather than accept a single member of the staff on the board the board as a whole would resign. They have not resigned. They have taken the recommendation very tamely, with a complacency that is more creditable to their fortitude than to their pride. But at this moment Mr. Russell cannot refrain from another hit at the medical staff through the medical profession. For the suggestion is that provision should be made in Rule 31 that of the 10 ordinary members of the board not one under any circumstances, besides those appointed by the staff, shall be members of the medical profession. That is, I think, a suggestion most unfair in restricting the choice of governors and it is a gratuitous insult to the medical profession. We may have in the future some medical man willing to bestow, say, £20,000 on a charity; is it likely that he will be anxious to give the money to an institution in which medical men are excluded

from any share in the management? I think not. Let me point out the inconsistency of the suggestion. The board have told us they have had medical men on the staff, they have had Dr. J. S. Ramskill and Dr. Russell Reynolds, and they admit that they rendered conspicuous and admirable service. The board say that these gentlemen were opposed to the views of the medical staff, that they sided generally with the policy of the lay members of the board, and, therefore, gentlemen, I infer that there need be no fear in appointing medical men on the board and there will be no unfair influence exerted by them at the board.

Sir HENRY BURDETT: Rule 41 provides, "There shall be a secretary, a senior house physician, and a lady superintendent who shall have the sole control of their respective departments under the board, and whose duties shall be defined by the board and embodied in the by-laws. It shall be their duty to report to the board and in all cases of difficulty to consult, so far as possible, the chairman, or failing him the vice-chairman, and to act in accordance with his advice." Is it the intention of the committee who made this recommendation that these by-laws shall embody the recommendation of Sir Edward Fry's report on p. 17 to the following effect: "that a resident medical superintendent should be appointed as a permanent official, who should not only discharge the duties of the senior house physician, but should also be the responsible and resident head of the whole institution under the Board of Management?"

The CHAIRMAN: Your question is whether the intention of the committee was that the board should carry out the recommendations of Sir Edward Fry's report.

Sir HENRY BURDETT: They recommend the appointment of a senior resident physician. I want to know if they carry out the recommendation that he shall be the resident medical superintendent.

The CHAIRMAN: It is obvious that that question cannot be answered here; it is a question for the new board to decide. The committee have decided that these three officials are to have co-ordinate powers and to have sole control of their respective departments, and their duties are to be defined by the board and embodied in the by-laws, and therefore that that question must be left entirely for the by-laws.

Sir HENRY BURDETT: I propose to move an amendment. I think it is a matter involving a very important principle and the whole future of the institution will depend upon the decision of this question, and my amendment is that we should add to this by-law words which will embody the recommendation of Sir Edward Fry's report—namely, recommendation No. 2 on p. 17—that a resident medical superintendent should be appointed as a permanent official. I therefore propose to put in after the words "senior house physician" "who shall act as resident medical superintendent, to be appointed as a permanent official, who shall not only discharge the duties of the senior house physician but shall also be the responsible and resident head of the whole institution under the Board of Management." Those are the words of Sir Edward Fry's committee, and I will beg you to keep your attention on that, and I do so for this reason, because in an institution of this kind where we have patients who from the very nature of their malady are long resident in this institution it is essential that there should be a head. I do it, too, because in this institution we have had a great dispute between the board and the staff which I do not propose to go into, which has centred round the rights of the medical profession, and I believe that there is no doubt that in an institution like this it is most important for everybody that you should have a responsible head and that that head should be a medical man. I hope that we may not have a division on this, but that we may accept the recommendation which has been made by Sir Edward Fry simply as men of business. It is giving the medical staff more than they ask for.

Mr. R. A. BENNET: I will second the amendment.

Dr. CHARLTON BASTIAN: I should like to say something first of all in favour of this Rule 41. I happen to have been for 30 years a physician at a hospital where practically what is intended in this rule has had effect, and during the whole of that time I may say that I have never known of any difficulty whatsoever arising in regard to it. There has been at University College Hospital, the hospital to which I allude, a resident medical officer, and the resident medical officer has had the supreme control of all affairs connected with the medical department, the general medical superintendence of the hospital. There have been a sister superior and a lady superior and a secretary, and there has never been any sort of collision or difficulty that I have heard of with these three officers working in that way. Of course, the committee of the hospital have met once a week and any question that would have to be referred to them could then be always referred to them, and here I take it also that a board would probably meet, or if not a board a committee of that board once a week, and that any question that arose would be decided then, but there is no likelihood at all that there would be any difficulty if you have a man with some experience as senior house physician or resident medical officer, or whatever he may be called. In regard to another point, I think it is a matter of considerable importance whether we have a permanent medical superintendent or whether we have a man whom, I think, it would be better to call the resident medical officer, elected for a short term of years. I think it would be a decided mistake to have a permanent medical officer in this hospital. In hospitals there are always men who have gone through the appointments of house surgeon and house physician, and who have, perhaps, held other appointments at other hospitals, who know perfectly well all the arrangements and all that is necessary to carry on the work of a hospital properly, and those are the men who come up for such an appointment as that of resident medical officer of a hospital. I believe there are several hospitals which are practically managed in that way. A man that has had this experience at hospitals is elected as resident medical officer and comes in for two or three years—I think it is three years at University College—and he is subject to re-election if needful. There is never any difficulty in getting a good and suitable man of that kind for those posts, and the affairs of the hospital can be perfectly well carried out with such arrangements, the resident medical officer being the authority to whom medical questions are brought, the matron and secretary attending to their own work. I believe it is much better that we should not have a permanent medical superintendent but a resident medical officer, who shall be elected for two or three years and be subject to re-election. It is really absolutely necessary that we should have some increase in this hospital. There are at present only two resident medical officers, and this hospital is one in which an enormous amount of work devolves upon such officers, far more than in most hospitals. In the first place

because of the very great complexity of the cases and the long histories. Therefore, I think there would be abundant work for a third man. The resident medical officer would have general superintendence and some part of the work of the house physician.

Mr. GREEN: I should like to point out exactly to the governors why I hope the rule will not be altered. There is no rule to which the committee gave more thought, and we came to the conclusion ultimately that this was the best rule. I think we gave twice as much thought to this rule as to any other. I think Sir Henry Burdett has not quite grasped the recommendations of the Committee of Inquiry of Section 79. He only reads the second alternative and says, Do you mean to have a resident medical superintendent appointed as a permanent official? We have, however, the other alternative, which we have adopted. We are following the other recommendation of the Committee of Inquiry and it was that the hospital should be carried on under the following schemes of government. The secretary should be entrusted with the ordinary duties of a secretary and that in addition he should be a chief executive officer of the Board of Management—do not think that means a director back again—but should be restrained from interfering in any way with the lady superintendent and the members of the medical and resident staffs and with all persons and things placed under their control, and that the house physician, lady superintendent, and secretary should be required in all cases of difficulty to consult, so far as possible, the chairman or vice-chairman of the board and to act in accordance with his advice. That is what has been carried out. We have made this qualification, that we have not put in any word about restraint. Instead of saying that anyone shall be restrained we have said what the duties shall be. We shall not put a man under the fetter of being restrained in such a manner. In one sense things must overlap, and in one sense everything is concerned with the secretary because nearly everything comes down to the drawing of a cheque and the secretary must know what he is drawing a cheque for. You cannot rid him of that knowledge and we have not gone quite so far as that, but we have done what we believe and all of us believe to be the best practical thing and I do hope there may be no alteration whatever to this rule.

Sir FELIX SEMON: May I say as one of the members of the Reconstruction Committee that we are all heartily in accord with the words of Mr. Green? We are perfectly satisfied with the arrangements as recommended by that committee and the medical staff will do everything to avoid friction and give a fair trial to the proposal.

The amendment, proposed by Sir HENRY BURDETT, was put to the meeting and declared lost.

Mr. GEORGE W. E. RUSSELL: I at any rate shall not give any trouble in respect to the direction laid down at the beginning of the meeting by the Chairman about wasting our time. It requires a very pugnacious spirit to retain its pugnacity for two years, and for my own part nothing can be more amicable as regards all personal relations than my present intention. If Mr. Green and Sir James Crichton Browne thought that I was, to use a popular phrase, going to be drawn by their allusions to the circular I am afraid I shall have to disappoint them. It is quite true that it was signed by me—my connexion with the matter consisted in that only. I did not suggest or contribute a line or a word to it. I do not say whether I agree or not with its tenor, but it is not due to me that it is issued to the governors; I merely signed it *pro hac vice et pro re nata*, being placed in the chair at the time, and there my connexion with it ends, and I will not follow any of the suggestions made, nor is it necessary for me to take any further notice. I must not be misunderstood to express any protest against my colleagues who did agree with it. In what I am going to say I think it is a matter of duty to mention that my colleagues have no part or lot in the course which I take as an individual. I am not speaking for the board or behind the board or with any tacit understanding of the board or at the suggestion of the board; the same disclaimer I must make with regard to two officials—namely, Mr. Burford Rawlings and Mr. Bower. My object in rising is to meet the motion moved by Mr. Green and seconded by Sir James Crichton Browne with a direct negative. For my own part I will make my remarks as short as possible. I will simply state that the rules are well as they are. I do not say unimprovably good—that would be ridiculous—but only susceptible to improvement in small details which could be very well dealt with by the board as it already exists or as it will be when altered at any subsequent election. The great fundamental question which underlies the whole trouble was the question whether two members of the medical staff should be admitted to seats on the board. It is within the recollection of those who hear me to-day that throughout I—with no thought of personal reference to anybody, but simply for the sake of the hospital—have been of the opinion deliberately formed that to grant the demand of the medical staff for two seats on the Board of Management would be attended with inconvenient consequences. Sir James Crichton Browne made a direct personal reference to myself in this matter and I hope I shall be allowed to make some answer to him. The sense of it was that the board had altered its attitude with a zeal which did more credit to its fortitude than its pride. I am entirely in agreement with him. It will be in the recollection of many who hear me that at the meeting held early in August, 1900, I was in the chair speaking on behalf of the board in the strongest possible sense hostile to the admission of two members of the medical staff to the Board of Management. At that time I spoke, so far as my belief goes, the unanimous sentiments of the whole board save and except one member. Then came the autumn of that year and the long controversy in the columns of the *Times*, and when the board resumed its deliberations in the fall of the year it became apparent that a very considerable change had passed over the mind of the board. It was not, as far as I know, that anyone thought it desirable to admit these two members to the board, but the board had now come round to think it desirable to submit the matter to inquiry. In August we were under no circumstances ready to submit the matter to any external authority, and, as everyone here knows, it was only during the autumn of that year that a complete change came over the minds of the board in favour of submitting the question to arbitration, and I confess I think that the good-natured sarcasms of Sir James Crichton Browne were justly merited and justly applied, but as a matter of personal explanation I would like to say that whatever change occurred in the mind of my colleagues no change occurred in my own.

A GOVERNOR: You ruled that the discussion should be for the future and not about the past. The present speaker is referring to the past.

The CHAIRMAN: I think that Mr. Russell is giving a personal explanation of his own views to-day in opposing these rules and I think he

is quite justified in doing so. Whether it is wise for him as an individual is quite another thing.

Mr. RUSSELL: If the gentleman who has just spoken is at all conversant with public meetings he would know that everybody is entitled by the courtesy of such meeting to make a personal explanation.

The GOVERNOR: Thank you for the information.

Mr. RUSSELL: As far as I am concerned my withers are quite unwrung by Sir James Crichton Browne's criticism. I only wish to make clear to those present that the fact that I have been so constantly in the chair made it impossible for me to express my opinion or try to enforce it upon my colleagues as I should like to have done if I had been merely a member of the board, because the chairman is not entitled, I think, to press his own opinion, and I have been swamped so far by the opinion of my colleagues, who came to the conclusion that the question should be submitted to arbitration. I strongly hold that no case has been made out for revolutionising the rules of the hospital under which it has lived and flourished up till now and to substitute for them a new constitution. I move a direct negative to Mr. Green's proposition.

The CHAIRMAN: It has been moved and seconded that the report of the Committee of Reconstruction be adopted.

The motion was put to the meeting and declared carried.

The CHAIRMAN saying: I declare that that part of the report dealing with the rules is carried, and these rules are adopted (loud applause).

Mr. RUSSELL: I wish to call your attention to the existing rule No. 4, paragraphs 6 and 7, which regulate the demand for a ballot. This cannot be granted unless five governors demand it.

Five governors did not demand a ballot and the business of the meeting was continued.

The meeting then proceeded to the consideration of the second portion of the report of the Committee of Reconstruction dealing with the proposed pension for Mr. Burford Rawlings. The following gentlemen took part in the protracted discussion on this subject: The CHAIRMAN, Mr. GREEN, Mr. J. H. NELSON, Mr. J. WIGAN, Sir JOHN PAGET, Mr. J. PEARMAN, and Sir H. BURDETT. It was ultimately agreed that in addition to a pension of £450 Mr. Burford Rawlings should be presented with the amount of one year's salary, £800.

The usual vote of thanks to the Chairman ended the meeting.

## THE ELECTION OF DIRECT REPRESENTATIVES.

WE have received this message from Dr. W. Bruce addressed to the medical profession of Scotland:—

Dr. Bruce begs to thank the Scottish registered medical practitioners to the number of 975 who by their votes placed him at the top of the poll at the late election. Especially he wishes to express his most grateful thanks to the large number of those who have taken the trouble to personally congratulate him on his victory.

Now that the fight is over he assures the constituency generally of his desire to give his utmost energies towards advancing their interests in so far as it may be in his power to do so during his term of office.

We have also received the following letter from Dr. C. W. Hayward:—

To the Editors of THE LANCET.

SIRS,—I trust you will permit me to thank, through the medium of your columns, all those members of the medical profession who were kind enough to record their votes for me at the recent election. Considering the lateness of the hour when I came forward, and the consequently exceedingly limited opportunities I had of placing my views personally before the electorate, I believe that the number is a record for a candidate's first appearance. I therefore hope that on some future occasion they will again do me the favour of voting for me, and that with their votes as a nucleus I may be able to obtain sufficient new supporters to enable me to devote myself to doing the utmost of which I may be capable in the true interests of the general medical profession.

I am, Sirs, yours faithfully.

CHARLES W. HAYWARD.

Grove-street, Liverpool, Dec. 15th, 1901.

To the Editors of THE LANCET.

SIRS,—The official figures published by the returning officer show that the number of votes recorded for me at the recent election of Direct Representatives was 5569 and not 5369 as stated on page 1693 of THE LANCET of Dec. 14th.

I am, Sirs, yours faithfully,

Gilson-square, N., Dec. 18th, 1901.

GEORGE BROWN.

WE regret to have omitted the name of Mr. H. Betham Robinson in giving a list of those members of the surgical staff of St. Thomas's Hospital who were present at the funeral of Sir William Mac Cormac.

## VITAL STATISTICS.

## HEALTH OF ENGLISH TOWNS.

In 33 of the largest English towns 5752 births and 4076 deaths were registered during the week ending Dec. 14th. The annual rate of mortality in these towns, which had been 21.3, 20.3, and 19.5 per 1000 in the three preceding weeks, further declined last week to 18.5 per 1000. In London the death-rate was equal to 18.5 per 1000, while it averaged 18.6 in the 32 large provincial towns. Among these large towns the lowest death-rates were 11.0 in Blackburn, 12.8 in Croydon, 13.3 in Derby, and 14.3 in Huddersfield and in Bradford; the highest rates were 21.6 in Sheffield, 22.1 in Preston, 22.6 in Birmingham, 22.7 in Plymouth, and 24.7 in Oldham. The 4076 deaths in these towns last week included 414 which were referred to the principal zymotic diseases, against 473, 434, and 418 in the three preceding weeks; of these 414 deaths 145 resulted from measles, 73 from diphtheria, 55 from whooping-cough, 40 from "fever" (principally enteric), 38 from scarlet fever, 36 from diarrhoeal diseases, and 27 from small-pox. No death from any of these diseases occurred last week in Cardiff; in the other towns they caused the lowest death-rates in Croydon, Plymouth, Nottingham, Huddersfield, and Bradford, and the highest rates in Birmingham, Norwich, Birkenhead, Liverpool, and Blackburn. The greatest proportional mortality from measles was recorded in Norwich, Manchester, Oldham, Blackburn, Preston, Halifax, and Sheffield; from scarlet fever in Newcastle; from whooping-cough in Liverpool; and from diarrhoeal diseases in Swansea and Burnley. The mortality from "fever" showed no marked excess in any of the large towns. The 73 deaths from diphtheria included 31 in London, six in Liverpool, five in Salford, three in Brighton, three in Portsmouth, three in Bristol, three in Birkenhead, and three in Sheffield. 26 deaths from small-pox were registered last week in London and one in Birmingham, but not one in any of the 33 large towns. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals at the end of the week was 506, against 396, 427, and 474 on the three preceding Saturdays; 134 new cases were admitted during the week, against 141, 123, and 170 in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital, which had been 3336, 3278, and 3241 at the end of the three preceding weeks, had further declined to 3188 on Saturday, Dec. 14th; 332 new cases were admitted during the week, against 379, 320, and 376 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 582, 534, and 470 in the three preceding weeks, further decreased last week to 427, and were equal to the corrected average number. The causes of 52, or 1.3 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Cardiff, Leeds, Sunderland, and in 10 other smaller towns. The largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Manchester, Sheffield, and Gateshead.

## HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 22.2 and 20.5 per 1000 in the two preceding weeks, rose again to 20.7 during the week ending Dec. 14th, and showed an excess of 2.2 per 1000 over the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 15.0 in Paisley and 16.1 in Leith to 21.6 in Glasgow and 24.8 in Dundee. The 660 deaths in these towns included 28 which were referred to measles, 15 to diarrhoea, 11 to "fever," nine to whooping-cough, four to scarlet fever, and three to diphtheria. In all, 70 deaths resulted from these principal zymotic diseases last week, against 85, 77, and 72 in the three preceding weeks. These 70 deaths were equal to an annual rate of 2.2 per 1000, which was 0.3 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of measles, which had been 29, 29, and 23 in the three preceding weeks, rose again last week to 28, of which 19 occurred in Glasgow, six in Dundee, and two in Paisley. The deaths from diarrhoea, which had been 21 in each of the two preceding

weeks, declined to 15 last week, and included six in Glasgow, five in Dundee, two in Edinburgh, and two in Perth. The deaths referred to different forms of "fever," which had been eight, nine, and 10 in the three preceding weeks, further rose last week to 11, of which seven were registered in Glasgow, two in Edinburgh, and two in Paisley. The fatal cases of whooping-cough, which had been seven and four in the two preceding weeks, increased again to nine last week, and included seven in Glasgow. The deaths from scarlet fever, which had been three and nine in the two preceding weeks, declined again last week to four, of which three were registered in Edinburgh. The three fatal cases of diphtheria showed a marked decline from recent weekly numbers. The deaths referred to diseases of the respiratory organs in these towns, which had been 186 and 180 in the two preceding weeks, further declined last week to 165, but were 29 in excess of the number in the corresponding period of last year. The causes of 22, or more than 3 per cent., of the deaths in these eight towns last week were not certified.

## HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23.8, 18.8, and 20.2 per 1000 in the three preceding weeks, declined again to 17.9 per 1000 during the week ending Dec. 14th. During the past four weeks the death-rate has averaged 20.2 per 1000, the rates during the same period being 20.2 in London and 19.8 in Edinburgh. The 129 deaths belonging to Dublin registered during the week under notice showed a decline of 16 from the number in the preceding week, and included one death from whooping-cough, but not one from any other of the principal zymotic diseases. The zymotic death-rate for the week was thus only 0.1 per 1000, against 1.9 in London and 1.6 in Edinburgh. In no previous week of this year had the number of deaths referred to the seven principal zymotic diseases been less than five. The 129 deaths in Dublin last week included 19 of children under one year of age and 34 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a decline of four from the respective numbers recorded in the preceding week. One death from violence and three inquest cases were registered, and 38, or nearly a third, of the deaths occurred in public institutions. The causes of seven, or more than 5 per cent., of the deaths in Dublin last week were not certified.

## VITAL STATISTICS OF LONDON DURING NOVEMBER, 1901.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in each of the cities and boroughs in the county of London. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 11.6 per 1000 of the population, provisionally estimated at 4,543,757 persons in the middle of the year. In the three preceding months the rates had been 8.6, 12.4, and 13.8 per 1000 respectively. The rates were considerably below the average in Kensington, Hammersmith, Chelsea, Hampstead, Lambeth, Lewisham, and Woolwich; while they showed the largest excess in St. Pancras, Hackney, Holborn, Southwark, Bermondsey, and Camberwell. During the four weeks ending Nov. 30th, 413 cases of small-pox were notified in London, against 94, 157, and 347 in the three preceding months; 52 cases belonged to Holborn, 44 to Stepney, 43 to St. Pancras, 36 to the City of Westminster, 30 to Bermondsey, 28 to Finsbury, and 28 to Camberwell. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals, which had been 74, 163, and 284 at the end of the three preceding months, had further risen to 427 at the end of November; the weekly admissions averaged 110, against 23, 44, and 72 in the three preceding months. The prevalence of scarlet fever showed a marked decline from that recorded in the preceding month; among the various metropolitan boroughs this disease was proportionally most prevalent in Southwark, Bermondsey, Camberwell, Deptford, and Greenwich. The Metropolitan Asylums hospitals contained 3186 scarlet fever patients on Saturday, Nov. 30th, against 2971, 3096, and 3281 at the end of the three preceding months; the weekly admissions averaged 352, against 288, 412, and 399 in the three preceding months. During the month under notice diphtheria was considerably less prevalent than in the preceding month; the greatest proportional prevalence of this disease occurred

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING NOVEMBER, 1901.  
(Specially compiled for THE LANCET.)

TOWNS AND BOROUGH.	Estimated population in the middle of 1901.	NOTIFIED CASES OF INFECTIOUS DISEASE.							DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.										Deaths from all causes.	Death-rate per 1000 living.	Deaths of infants under one year to 1000 births.

\* Including membranous croup.

in Fulham, St. Pancras, Hackney, Poplar, Wandsworth, and Deptford. There were 1504 diphtheria patients under treatment in the Metropolitan Asylums hospitals at the end of last month, against 1336, 1499, and 1570 at the end of the three preceding months; the weekly admissions averaged 200, against 177, 248, and 243 in the three preceding months. The prevalence of enteric fever showed a marked decline from that in recent months; among the various metropolitan boroughs the greatest proportional prevalence of this disease occurred in St. Pancras, Islington, Finsbury, Bethnal Green, Stepney, Poplar, Bermondsey, and Deptford. The number of enteric fever patients under treatment in the Metropolitan Asylums hospitals, which had been 225, 292, and 291 at the end of the three preceding months, had further declined to 245 at the end of November; the weekly admissions averaged 32, against 42, 50, and 38 in the three preceding months. Erysipelas was proportionally most prevalent in St. Pancras, Hackney, Holborn, Shoreditch, Stepney, and Southwark. The 25 cases of puerperal fever notified during the month included four in Stepney, three in Hackney, two in St. Pancras, two in Islington, and two in Southwark.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occurring in the public institutions of London having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ending Nov. 30th the deaths of 6984 persons belonging to London were registered, equal to an annual rate of 20.0 per 1000, against 15.4 per 1000 in each of the two preceding months. The lowest death-rates in the various metropolitan boroughs were 10.8 in Hampstead, 13.5 in Stoke Newington, 14.3 in Lewisham, 14.9 in Woolwich, 15.2 in Chelsea, and 15.9 in St. Marylebone; the highest rates were 25.1 in Stepney, 25.5 in Shoreditch and in Southwark, 26.1 in Finsbury, 26.6 in Bermondsey, and 27.5 in Holborn. The 6984 deaths from all causes during the month included 622 which were referred to the principal zymotic diseases; of these 73 resulted from small-pox, 201 from measles, 38 from scarlet fever, 140 from diphtheria, 52 from whooping-cough, 52 from enteric fever, two from simple continued fever, and 64 from diarrhoeal diseases. The lowest death-rates last month from these diseases were recorded in Chelsea, St. Marylebone, Hampstead, Stoke Newington, Hackney, and Greenwich, and the highest rates in Kensington, Islington, Holborn, Finsbury, Bermondsey, and Battersea. The 73 fatal cases of small-pox greatly exceeded the average, and included fourteen in Holborn, nine in the city of Westminster, eight in St. Pancras, seven in Stepney, six in Southwark, and six in Camberwell. The 201 deaths from measles showed a slight increase upon the average number in the corresponding periods of the 10 preceding years; among the various metropolitan boroughs this disease was proportionally most fatal in Kensington, Hammersmith, Islington, Finsbury, Lambeth, and Battersea. The 38 fatal cases of scarlet fever were less than one-half of the corrected average number; the greatest proportional fatality from this disease occurred in St. Marylebone, Finsbury, Bermondsey, Lambeth, and Camberwell. The 140 deaths from diphtheria were 62 below the average number in the corresponding periods of the 10 preceding years; this disease showed the highest proportional fatality in Paddington, St. Pancras, Islington, Holborn, Shoreditch, Bethnal Green, Poplar, and Camberwell. The 52 fatal cases of whooping-cough showed a marked decline from the corrected average number; among the various metropolitan boroughs whooping-cough was proportionally most fatal in Finsbury, Shoreditch, Bermondsey, Battersea, and Lewisham. The deaths referred to "fever" last week numbered 54, against an average of 90 in the corresponding period of the 10 preceding years; the "fever" death-rate was highest in Fulham, Islington, Bethnal Green, Bermondsey, Battersea, and Deptford. The 64 fatal cases of diarrhoea were just equal to the corrected average number; among the various metropolitan boroughs the greatest proportional fatality from this disease was recorded in Kensington, Hammersmith, Fulham, Finsbury, Southwark, and Deptford. In conclusion, it may be stated that the aggregate mortality in London from these diseases during November was nearly 13 per cent. below the average.

Infant mortality in London last month, measured by the proportion of deaths among children under one year of age to registered births, was equal to 165 per 1000. The lowest rates of infant mortality were recorded in St. Marylebone, Hampstead, St. Pancras, City of London, Lewisham, and

Woolwich; and the highest rates in Kensington, Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, and Bermondsey.

## THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons:—T. E. H. Williams to the *President* for R.N. Rendezvous and at medical department, and H. A. W. Richardson to the *Defiance*. Staff Surgeon E. J. Morley to the *Magnificent*.

### ARMY MEDICAL SERVICE.

Surgeon-General W. Taylor, C.B., Honorary Physician to the King, to be Director-General, vice Surgeon-General A. F. Preston, Honorary Physician to the King, whose tenure of the temporary appointment has expired. Dated Dec. 2nd, 1901.

Lieutenant-Colonel A. Keogh, C.B., R.A.M.C., has been selected for the appointment of Deputy Director-General, with the temporary rank of Surgeon-General, from Jan. 1st, 1902, on the retirement of Surgeon-General H. S. Muir, C.B.

### ROYAL ARMY MEDICAL CORPS.

Major W. Lewis Gray has arrived in the Southern District for duty and has taken over charge of the station hospital, Parkhurst. Lieutenant-Colonel D. Bruce proceeds from London to Aldershot for duty.

### INDIA AND THE INDIAN MEDICAL SERVICES.

The King has approved of the following promotions among the officers of the Indian Medical Service:—Majors to be Lieutenant-Colonels (dated Oct. 1st, 1901): *Bengal Establishment*: James Barry Gibbons, Donald St. John Dundas Grant, and Dirom Grey Crawford. *Madras Establishment*: Robert Bradley Roe, John Smyth, Hugh Greany, and Edward Pettingall Youngerman. Captains to be Majors (dated Sept. 30th, 1901): *Bengal Establishment*: Henry Bruce Melville, Joseph Charles Stoelke Vaughan, Alexander Leonard Duke, Joshua Chaytor White, Harry William Elphick, and Charles Henry Bedford. *Madras Establishment*: Charles Louis Williams and Wilfrid Constant Vickers. *Bombay Establishment*: John Blackburn Smith and Henry Francis Cleveland.

The King has also approved of the retirement from the service of the undermentioned officers:—*Bengal Establishment*: Lieutenant-Colonel John Manook Zorab (dated Oct. 9th, 1901); Lieutenant-Colonel Frederic Daly Caesar Hawkins (dated Oct. 26th, 1901) [this notification supersedes that of the transfer to the half-pay list of Lieutenant-Colonel Hawkins made in the *London Gazette* of Nov. 26th, 1901]; Lieutenant-Colonel Patrick Mullane (dated Nov. 1st, 1901).

### VOLUNTEER CORPS.

*Artillery*: 1st Gloucestershire: Surgeon-Lieutenant W. J. Hill to be Surgeon-Captain. *Royal Engineers* (Volunteers): 1st Lancashire: George Arthur Hawkins-Ambler is re-appointed Surgeon-Captain. *Rifle*: 1st Volunteer Battalion the Suffolk Regiment: Surgeon-Lieutenant F. Ward to be Surgeon-Captain. 1st Roxburgh and Selkirk (the Border): Brigade-Surgeon-Lieutenant-Colonel G. H. Turnbull is seconded whilst holding the appointment of Senior Medical Officer to the Scottish Border Volunteer Infantry Brigade. 3rd Lanarkshire: Surgeon-Lieutenant A. S. Tindal to be Surgeon-Captain. 3rd (Sunderland) Volunteer Battalion the Durham Light Infantry: Surgeon-Captain J. C. Fenwick resigns his commission.

### ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant-Colonel H. M. Morgan having retired from the Volunteer Forces ceases to belong to the Army Medical Reserve of Officers.

### SOUTH AFRICAN WAR NOTES.

The following have been discharged from hospital to duty:—Major O. R. A. Julian, R.A.M.C., Lieutenant J. M. Buist, R.A.M.C., and Civil Surgeons Macauley, Clarke, Newland, Clements, and Walker.

### SOME GERMAN SUGGESTIONS ABOUT ARMY MEDICAL REFORM.

Our contemporary the *Outlook* last week had a long article based upon a communication which it had received from a high German authority *apropos* of the Government proposals for the re-organisation of the Army Medical Service

in this country. It appears that the new War Office scheme has attracted attention in Germany and abroad among those who have been studying the whole question of army reform. A good many points are taken up and discussed in the communication in question—which requires (and well deserves) to be read as a whole to be rightly appreciated and understood—and among others the institution of an Advisory Board is regarded as a necessity. The fact that the German Government has within the last six months established a “scientific senate” acting as an Advisory Board to the Director-General (*Generalstabamt der Armes*) is adduced in support of that view. This senate is a large one, and in addition to its ordinary members it includes a number of eminent specialists in every branch of medical science. The board controls the course of study, the plans of post-graduate courses, questions of sanitation and hygiene, research on diseases of the army and their treatment, &c. The German correspondent of the *Outlook* would have a much larger board than that proposed in Mr. Brodrick's new scheme, and he thinks that in order to make an efficient and representative organisation appointments to the posts of consulting physicians and surgeons to the army should be made in time of peace by the Crown acting on the advice of the Secretary of State for War. In this way it is contended that the most eminent practitioners of the day would be made available and would regard their selection for such appointments as an honour and distinction. He considers that the number and range of the examinations set forth in the War Office scheme, if carried out, would tend to repel instead of to attract medical candidates and proposes a system of scholarships similar to those in vogue in the German service and makes several other suggestions. The German scheme as outlined in the *Outlook* is a big affair and would, we fear, be difficult to carry out in this country. In summing up the various points of his communication the German authority adds: 1. Induce young men to join the Royal Army Medical Corps by giving them scholarships. 2. During their candidature test their medical and social qualifications. 3. By frequent scientific courses and liberal grants of “study leave” stimulate the officers to replenish and increase their knowledge. 4. Promotion to take place by seniority, but subject to confidential reports from various sources (military and civil) up to the rank of lieutenant-colonel. 5. All higher posts to be granted, without regard to seniority, on grounds of general merit or distinction in the service, by the Director-General.

#### AFFAIRS IN SOUTH AFRICA.

As far as the purely military news is concerned it may be very briefly summed up as mainly consisting in the extension of the blockhouse system, General Bruce Hamilton's recent attacks upon, and capture of, Boer laagers, and the capture of Commandant Kritzinger. A good deal of sickness still continues in South Africa, but not more than might be expected to make its appearance under the circumstances. The names of those returned as dangerously ill amount to about 100, enteric fever occupying, as usual, the chief position. The casualties from wounds have to be added, of course, to the returns of sickness. The death-rate from all causes happily does not appear to be a heavy one. The *Times* of Dec. 16th contains an interesting and instructive article reviewing the recently published blue-book of 131 pages relating to the working of the refugee camps in the Transvaal, Orange River Colony, Cape Colony, and Natal. The report of Dr. Pratt Yule on the general medical condition of the camps in the Orange River Colony is well worth reading. The subject of camp diseases in relation to camp sanitation is taken up and commented upon and much is said about such diseases as measles, whooping-cough and pneumonia which have been so widely prevalent in the concentration camps. After stating, among other things, that it is well known to military officers that camping grounds quickly become foul under the best circumstances, he goes on to call attention to the important point that the urine of patients convalescent from typhoid fever often contains a pure culture of the typhoid germ, which, by the methods of disposal pursued in refugee camps, becomes blown about in the dust, and he states his belief that the typhoid infection of camps is principally air-borne. Dr. Pratt Yule is also of opinion that the extraordinary frequency of pneumonia and lung disease generally in these camps is commonly attributable to some air-borne infection, due in part to the increasing pollution of camping-grounds.

#### THE REFORM OF THE ARMY MEDICAL SERVICES.

Among the number and variety of unfavourable criticisms

which the report of Mr. Brodrick's War Office Committee has called forth we notice that it is generally, but somewhat hastily we think, assumed that the medical officers now serving under existing regulations will be deprived (without any compensatory advantage) of the privilege of retiring on £1 a day after 20 years' service. We cannot believe that this is intended to be the case. According to our reading there is nothing definite in the report to indicate that such a proposal would be made applicable to medical officers now serving, but only to those who may hereafter enter under a new warrant—that is, supposing the proposal to be embodied in a forthcoming warrant which, if the authorities are wise, they are not likely to do.

#### FIELD HOSPITAL EQUIPMENT IN INDIA.

The following recommendations of the committee on the question of field hospital equipment in India will be given effect to from April 1st next:—(1) Changes in scale of commissariat and ordnance stores; (2) recommendations regarding field hospital boxes, flags, and tents; and (3) supply of perchloride of mercury. Congo stoves are to be given a further trial, a small portable stove to burn solidified spirits of wine and a lamp lantern for burning acetylene gas being provided. The question of a more liberal provision of the Roentgen ray apparatus is under consideration.

#### THE REFUGEE CAMPS.

A supplementary blue-book to the one already issued was published on Dec. 14th, dealing with the working of the refugee camps in the Transvaal, Orange River Colony, Cape Colony, and Natal. The reports contained in the book will reassure everyone that Mr. Chamberlain and the authorities concerned are making every effort to promote hygienic conditions in the camps which have been established by military needs.

#### THE MEMORIAL SERVICE AT ST. PAUL'S CATHEDRAL.

Among those who were present at the memorial service at St. Paul's Cathedral on Dec. 16th to commemorate those who have fallen in South Africa were Colonel Sir Thomas Gallwey, C.B., R.A.M.C. (representing the Director-General of the Army Medical Department) and Lieutenant-Colonel W. Babbie, V.C., R.A.M.C.

At an investiture, held at St. James's Palace on Dec. 17th, decorations and rewards granted in recent Gazettes were conferred by His Majesty the King.

## Correspondence.

“Audi alteram partem.”

### THE EDUCATION OF THE MEDICAL STUDENT AND THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS,—As I was unfortunately not able to be present at the late meeting of the General Medical Council perhaps you will allow me the opportunity of stating in THE LANCET that, had I been present at the discussion on the report of the Education Committee as regards the proposals submitted respectively by Dr. Bruce and Mr. Ball, I should have voted with the minority. I do not mean now to remark on the very complicated entanglements that have led up to these proposals and which seem to me to involve the risk of a very heavy fall for the General Medical Council if there should be an appeal to the Privy Council. I hope that the committee which has been appointed *ad hoc* will have this issue in mind, as it was very distinctly and significantly set forth in the Council by Dr. MacAlister. I regard it as unfortunate that the Council did not accept the recommendation of the Education Committee so far as the principle, at least, of the proposals is concerned, viz. :—

That the Council approves of the suggestion that the registration of a medical student should be postponed until he has passed a recognised examination in the preliminary scientific subjects, on the understanding that the subsequent course of professional study should occupy at least four academic years.

It seems to me that the acceptance of a proposition of this kind by the General Medical Council would not only have been a reconciling one as regards its own previous decisions (which are much more in need of reconciliation than some of us are willing to allow), but would have provided a *modus vivendi* as regards the present unfortunate deadlock with the English

Royal Colleges. In the event of an appeal to the Privy Council (which I need not say I greatly deprecate) it would certainly not be overlooked that the General Medical Council itself, notwithstanding its own Education Committee, had thrown away an opportunity of this kind by its vote upon their report. But these grounds, though sufficient in my opinion, would not have been the only grounds of my voting with the minority in this case. No notice was taken in the discussion of what has become apparent enough to some of us in Scotland—viz., that the main object of the institution of the fifth year of study by the General Medical Council is being gradually and insidiously invaded, in quite a different direction from that attributed, rightly or wrongly, to the English Royal Colleges. No one who attentively considers the matter can doubt, I think, that the main purpose of the addition of a fifth year to the compulsory period of a medical education was to provide an entirely separate clinical year, to be attended after the curriculum of lectures and other academic studies had been completed, on which account the regulations were deliberately so framed as to leave candidates perfectly uncontrolled as to the schools and hospitals at which these practical and all-important studies were to be conducted. This, however, is evidently not the view of the fifth year which was present to the mind of one member of the General Medical Council who (according to the report) "thought that it was in order to make room for chemistry, physics, and biology that the five years' curriculum had been instituted." It is true that a subsequent speaker rightly expressed a measure of "surprise" at this very significant and uncompromising idea, but all the same it shows very well the trend of actual experience. The early subjects, being in a position of vantage in virtue of their coming first in the curriculum, have gradually expanded their requirements so as virtually to take complete possession of the extra year; and "medicine, surgery, and midwifery"—the thoroughness of instruction in which is, observe, the very *raison d'être* of the General Medical Council—are shunted along, so that when the fifth year comes it is found to be crowded up with the remains of studies that ought, according to the original intention of the fifth or final year, to have been completed before it began. Now, while the attention of the General Medical Council has been engrossed, to what I think is a quite undue extent, with an apparent encroachment on the first year of the medical curriculum, this virtual evasion of the purpose of the final year has, so far as I have observed, received no attention at all. And yet a perfectly undisturbed year for practical and clinical work, outside what may be called the merely academic requirements of the medical curriculum, is surely a question of no less importance (to put it mildly) than whether physics, chemistry, and elementary biology are, or are not, to be studied in a medical school on the one hand, or as part of a general education on the other. As matters stand at present, unless we are to look forward shortly to a sixth year being added for the final practical subjects (and even, perhaps, in that case) it will be necessary for the General Medical Council to secure the proper application of the final year as an undisturbed period of clinical and practical studies by a ruling, not only that the elementary scientific subjects shall have one compulsory year and no more, but also that before entering on the "clinical year" evidence shall be put in that the whole curriculum of "lecture" subjects has been completed, so as to leave (according to the original intention) an undisturbed time and practical freedom of choice as regards the clinical subjects. The suggestions of Dr. Bruce and Mr. Ball, had they been more kindly received by the Council, would, I think, have led the way to a readjustment of the curriculum generally, in which something effective might have been introduced in the direction here indicated. I am not to be considered as disparaging the early scientific subjects in thus attempting to keep them in what seems to me their proper place; indeed, few men engaged in medical teaching have been more consistent throughout a long career in supporting these subjects and insisting on their value as a discipline. Much more might be written on this topic, but to save your space I will abstain from further remarks at present.

I am, Sirs, yours faithfully,

Edinburgh, Dec. 14th, 1901.

W. T. GAIRDNER.

## A QUESTIONABLE PUNISHMENT.

To the Editors of THE LANCET.

SIRS,—Four or five years ago an able and popular civil surgeon of the Indian Medical Service prescribed, by the merest slip of the pen, an overdose of strychnia. The native

compounder made up the prescription as it stood and the patient died in consequence. The compounder was, I believe, dismissed, and the civil surgeon not only lost his appointment, but has remained ever since under such a cloud with the Indian Government that his career seems to be ruined. It seems to me, if the facts are as I believe them to be, that the person to blame in this case was chiefly, if not entirely, the compounder. The civil surgeon was a most capable physician, and had taken one of the first places in the entrance examinations of the service. The mistake, therefore, was certainly not due to any ignorance on his part, but was the result of a pure accident in writing—an accident which may, and often does, happen even to the most careful prescribers. On the other hand, to make up a poisonous prescription—to measure out and to mix in a poisonous dose of a deadly drug like strychnia—is a deliberate action which can only be ascribed to the grossest ignorance on the part of the compounder, and, unless I am mistaken, the law in this country makes the compounder chiefly, if not solely, responsible in such cases.

It was, no doubt, right to take notice of the most unfortunate error made by the civil surgeon; it may have been even right to deprive him for the time of his responsible post. But is it quite right to ruin his career entirely merely for a momentary slip of the pen which, after all, would have had no evil consequence if the authorities who gave the punishment were more careful regarding the qualifications of the men whom they employ as compounders? I should like to take the opinion of your readers on this point with a view to further action if deemed necessary.

I am, Sirs, yours faithfully,

Liverpool, Dec. 14th, 1901. RONALD ROSS, F.R.C.S., F.R.S.

## THE METHODS OF EXAMINING FOR MOVEABLE KIDNEY.

To the Editors of THE LANCET.

SIRS,—Reading the valuable address on the subject of Moveable Kidney by Mr. Henry Morris in THE LANCET of Nov. 30th (p. 1467), I was much interested in his description of the *palpation néphroleptique* of Glénard. Without knowing that Glénard had originated this manœuvre, or that he had glorified it with such a lengthy name, I have been practising a similar proceeding for some years on the loins of every patient whose abdomen I have had to examine, and I should like to bear tribute to the excellence of the method. By the degree of mobility of the kidney can be estimated by the use of one hand alone, or by the use of both hands both kidneys can be simultaneously palpated. To examine the right kidney the fingers of the left hand are placed behind the right loin so that the first and second fingers are over the last rib, while the thumb compresses the loin from the front immediately below the costal margin. The patient being told to breathe quietly the loin is gently but firmly compressed between the fingers behind and the thumb in front, when the loin will be felt in the normal condition to be empty; the fingers and thumb in a thin subject are able to be brought within two inches of one another. The patient is now told to inspire deeply but quietly, and the compression of the loin being maintained the end of the kidney will be felt to butt against the barrier formed by the first finger behind and the thumb in front; indeed, if the inspiration be a powerful one the kidney, when unduly moveable, may forcibly separate them as it descends. When the lower end of the kidney touches the hand the thumb is gently relaxed, and as it is lifted (still maintaining some pressure) the kidney will be felt either wholly or in part to pass between the fingers and thumb. Unless the compression by the thumb be relaxed the kidney is unable to descend, but, on the other hand, a degree of pressure must be kept up, otherwise the abdominal wall by bulging forwards as inspiration proceeds will carry the thumb off the anterior surface of the kidney. Just at the height of inspiration, but before expiration has begun, the thumb, with a somewhat rolling motion upwards, sharply depresses the anterior parietes against the fingers behind, with the result that the kidney is caught between them. If the lower end is compressed the organ will be driven upwards under shelter of the ribs by a mechanism similar to that which children use when they express a cherry stone from between their finger and thumb. If, however, the mobility is such that the upper end of the organ is caught instead of the lower the same mechanism will force it downwards, and by keeping

the loin compressed it can be retained below the thumb for as long a time as the examiner pleases.

The right hand, previously passive, is now used to palpate the kidney in its abnormal position. When the examination is finished the right hand gently pushes the kidney upwards whilst the thumb of the left hand is raised to allow of its passage. As the organ returns the thumb can be seen to ride over it and the peculiar slipping sensation associated with its replacement is very noticeable. The use of the second hand, however, is not necessary if mobility alone is in question, and by using a hand for each loin both kidneys, if sufficiently moveable, can be fixed below the thumbs. Sometimes the sharp compressing movement nips the kidney exactly at its centre and it may then be held in this position, though this usually causes some pain.

The application of the method is rendered easier by the fortunate possession of long fingers, and particularly of a long thumb, but it undoubtedly has the advantage of enabling the kidney to be felt throughout late inspiration and early expiration; for although, as Mr. Morris points out, a deep inspiration produces a hardening and bulging forwards of the anterior abdominal wall, yet firm compression is able in most cases to resist this so long as the patient breathes quietly and not spasmodically. By using this method it will be found that (in women at least) the lower end of the right kidney can practically always, and that of the left kidney nearly always, be easily felt on deep quiet inspiration. My experience is limited to the examination of women, but in them I should certainly hesitate to call any kidney moveable above the upper end of which I found it impossible to get my thumb by using this manoeuvre.

I am, Sirs, yours faithfully,

W. F. VICTOR BONNEY, M.D., M.S. Lond.,  
Assistant Physician, Chelsea Hospital for Women.  
Devonshire-street, W., Dec. 14th, 1901.

## CANCER AMONG HINDOOS.

*To the Editors of THE LANCET.*

SIRS,—In THE LANCET of Oct. 5th, p. 939, Mr. C. B. Keetley, writing upon the subject of cancer, states that he had been informed by Dr. C. N. Saldanha that "Hindoos suffer comparatively little from cancer." Upon this statement of the comparative immunity of Hindoos from cancer both Dr. Saldanha and Mr. Keetley base certain arguments regarding the prophylaxis of the disease. I do not know in what part of India Dr. Saldanha gathered the experience upon which he bases his opinion, but his statement is certainly not correct so far as Southern India is concerned. On the contrary, in this part of India cancer is very prevalent amongst Hindoos and much more so than amongst Mahomedans. In the wards of the Madras General Hospital cases of cancer affecting Hindoos are almost always to be found. At the time that I write I have three Hindoos in my wards suffering from this disease. Indeed, so common is the affection here that there are few diseases that our students are so familiar with when they leave college as cancer. The disease is most frequently seen in the mouth, affecting the inner side of the cheek. Cancer of the perris is also very common, as well as cancer of the uterus and breast.

I am, Sirs, yours faithfully,

J. MAITLAND, M.D. Edin.,  
Lieutenant-Colonel, I.M.S.  
Madras, Nov. 28th, 1901.

## ADMINISTRATION OF CHLOROFORM.

*To the Editors of THE LANCET.*

SIRS,—One cannot, I think, deprecate too strongly the overweening assumption of perfect security from danger for any one method of administering an anæsthetic. I refer to the letter of Mr. C. J. Harris in THE LANCET of Dec. 14th, p. 1696. Neither, in my opinion, can one too strongly urge on enthusiasts such as Mr. Harris that, at present at least, we must aim at right administration to the individual, not to "the public." The conception of a perfectly safe anæsthesia to be conferred on all and sundry—be it by any one anæsthetic or by any method of dosage by that anæsthetic—is in our present condition of knowledge a conception only, not a realisation. "There are no rules in medicine," is an adage with a wide application. It cannot be too strongly urged on students that it is only by careful observation of every case that skill in anæsthetic administration can be obtained, and not by the blind adherence to any rule-of-thumb method of administration. Krohne's inhaler is an excellent and most useful apparatus, but it is not, as claimed for it, the solution

of the difficulty and dangers of chloroform administration. Any experienced anæsthetist will know that difficulties and dangers arise in the course, say, of severe abdominal operations, which cannot be overcome by any one method, or by any agency save common sense born of experience in the use of all methods. That anyone can in time be anæsthetised by the gradual and methodical use of a Krohne inhaler I am prepared to admit. But that I ought to be able to go to any and every case with no other methods in my head or apparatus in my bag I am not prepared to agree to. Surely, Sirs, difference of opinion in such an important matter does not imply "lack of clear thought" or of observation as Mr. Harris suggests.—I am, Sirs, yours faithfully,

S. HENNING BELFRAGE, M.D. Lond.,  
Senior Anæsthetist to the Samaritan Free Hospital.  
Montagu-place, W., Dec. 13th, 1901.

## THE BRITISH ELECTRO-THERAPEUTIC SOCIETY.

*To the Editors of THE LANCET.*

SIRS,—At a meeting held on Dec. 13th it was unanimously decided that a society be formed for the study of electricity in its relation to medical science and that the said society be named "The British Electro-Therapeutic," also that a provisional committee be appointed, to consist of Dr. W. S. Hedley, Dr. Lewis Jones, Dr. H. G. Turney, Dr. J. H. Bryant, Dr. George Herschell, Dr. J. T. Ashton, Dr. H. McClure, and Mr. Chisholm Williams, to take the necessary steps for the organisation of such a society and to report to a meeting to be convened for Jan. 10th, 1902.

I am, Sirs, yours faithfully,

CHISHOLM WILLIAMS.  
20, Bedford-square, W.C., Dec. 15th, 1901.

## DUODENAL ULCER AND ITS SURGICAL TREATMENT.

*To the Editors of THE LANCET.*

SIRS,—In speaking of perforation of a duodenal ulcer Mr. B. G. A. Moynihan, in his instructive paper on the subject in THE LANCET of Dec. 14th, p. 1656, indicates the direction which the fluid may be supposed to take—viz., to the hepatic flexure of the colon, along the outer side of the ascending portion, to the iliac fossa, and thence to the pelvis, &c.

I imagine that this applies to cases of sudden rupture and where much fluid escapes when a person is in the erect position, as in Mr. Moynihan's second case. To give the escaped fluid a chance of remaining localised it would seem in these cases of the utmost value to lay the patient in a recumbent position immediately, and to maintain him there at all costs. One so often sees patients brought to hospital who are suffering from ruptured gastric ulcer in vehicles which do not allow of their lying down. I believe that it is these journeys which are largely responsible for the wide extent of peritoneal infection. Recent inquiries into the anatomy of the right kidney pouch in the cadaver have convinced me of what great importance this area is for the localisation of pus and other fluids, especially those coming from the duodenal region. If the viscera be removed it will be seen that the hollow of the flank, of which the kidney pouch is the most dependent portion, sinks three inches below its lowest boundary wall, which is the brim of the pelvis. Pus or extravasated fluid, unless of very large amount, must find some difficulty in ascending this gradient in order to flow over the brim of the pelvis into its cavity while the patient is supine. And it is correspondingly much easier for appendicitic pus to pass down the flank and infect the kidney pouch. As the kidney pouch with its various diverticula under the liver and into the lesser omental sac is notably difficult to cleanse I should have been glad to have seen Mr. Moynihan recommend an incision at the outer side of the right kidney just below the last rib and drainage at that point. I am, Sirs, yours faithfully,

F. VICTOR MILWARD, F.R.C.S. Eng.  
Birmingham, Dec. 16th, 1901.

## SMALL-POX AND VACCINATION.

*To the Editors of THE LANCET.*

SIRS,—There are many letters written to the medical papers now on the above subject, and some of the remedies suggested for inefficient vaccination are amusing if not instructive. Surely at a time when small-pox is daily increasing in

London and steadily finding its way into the provinces the Local Government Board should do something, and I venture to suggest three things easy of doing. 1. As the objection to vaccination is entirely due to ignorance in the great majority of persons (I am frequently told when I ask a patient what he thinks vaccination really is, "Oh, you give small-pox to a cow and then put the stuff out of the spots into our arms") to get the school board authorities to have vaccination explained shortly and simply to the pupils once in every term. 2. To supply all medical practitioners at a reasonable charge with pure calf lymph, or to get an Act passed prohibiting anyone from selling calf lymph without a certificate from the Local Government Board, which Board should have power to visit and inspect premises, animals, and operations, and to take away lymph for bacteriological and other examinations. 3. To alter the present vaccination certificate by adding to the form, "has been successfully vaccinated by me," the words "in — places," and in any case where less than four places have been certified the vaccination officer should note such in his register and write to the parents or guardians of the child notifying that such vaccination is not protective for more than a few years and advise that the child should be revaccinated at or before the age of seven years.

I am, Sirs, yours faithfully,

Gravesend, Dec. 16th, 1901.

C. J. W. PINCHING.

### THE WILLIAM SMYTH FUND.

To the Editors of THE LANCET.

SIRS,—May I be permitted to make a suggestion of a practical character as to the method by which, I trust, the widow and eight orphan children of that manliest and bravest of men, the late William Smyth of Burton Port, Donegal, can be secured, as they certainly ought to be, from every fear of want. When the case was brought to my notice, after forwarding my individual subscription I undertook, at the suggestion of the gentleman who mentioned the matter to me, to write a letter to the Liverpool papers in which, after briefly setting forth the case, I offered to receive and acknowledge any monies forwarded to me. The response has been very kind and generous both on the part of the medical profession and the public, sums of various amounts have been sent to me, and I have been able thus far to transmit to Sir Christopher Nixon £350 (inclusive of my own subscription), while there are still some £40 to send. The suggestion which I wish to make is that a senior and thoroughly well-known medical man in each of the large towns and cities of England, Wales, and Scotland should undertake a similar duty for his own neighbourhood, appealing to patients as well as to his medical brethren. The result would not be in the least doubtful. Sir Christopher Nixon and the distinguished gentlemen associated with him will look after Ireland.—I am, Sirs, yours faithfully,

Liverpool, Dec. 16th, 1901.

WILLIAM CARTER.

### RASH AFTER TONSILLOTOMY.

To the Editors of THE LANCET.

SIRS.—In reply to the suggestion of Dr. Clement Dukes that the rash after tonsillotomy recently reported by me in THE LANCET was possibly the result of a soap-and-water enema, I should like to explain that no enema was administered in the case in question.

I am, Sirs, yours faithfully.

H. W. HENSHAW, M.R.C.S. Eng.,

Kew, Dec. 17th, 1901.

L.R.C.P. Lond., D.P.H.

### EXCESS OF SALT IN THE DIET A PROBABLE FACTOR IN THE CAUSATION OF CANCER.

To the Editors of THE LANCET.

SIRS.—It is not in opposition to Dr. James Braithwaite's theory<sup>1</sup> of "salt being a probable factor in the causation of cancer" that I write, but against the assertion that the Jewish race, owing to their dietary laws, are not so liable to the disease. Among orthodox Jewish people as soon as meat arrives at the house it is washed and then well sprinkled with

salt and allowed so to remain for half an hour or more, in order to dissolve out any fragments of blood that may remain in the tissues. That in itself is sufficient (if the salt theory be correct) to create a larger proportion of cases in the race *pro rata* to others. Though ham and bacon are excluded from their diet, let me assure Dr. Braithwaite that the latter is amply compensated for by smoked and pickled meats. No doubt, owing to their Oriental origin, Jewish people are particularly prone to dishes that are very highly seasoned, salt being one of the main ingredients. In conclusion, I could enumerate many cases of carcinoma amongst my friends and patients during the last few years, most of them never having tasted swine-flesh.

I am, Sirs, yours faithfully,

M. BERNSTEIN, L.R.C.P. Edin. &c.

Edgbaston, Dec. 10th, 1901.

To the Editors of THE LANCET.

SIRS.—In THE LANCET of Dec. 14th, p. 1686, you make the following remark upon the subject of my paper on the causation of cancer:—

We believe, however, that a more systematic and widespread inquiry would show that cancer is not so uncommon amongst women and men of Jewish birth as has hitherto been supposed.

I think that I have tapped every source of information possible on this point and I send you the following extract from my paper, an abstract of which only has yet been published:—

Dr. Abraham Cohen, physician to the Jewish out-patients at the Metropolitan Free Hospital, has very kindly looked up the registered causes of death of those buried by the United Synagogues of London. This covers the whole Jewish population of London with the exception of about 5000 or 6000 who do not belong to the Union. In the years 1899, 1900, and 10 months of 1901 there were registered 62 deaths from cancer: uterus two, breast nine, liver four, rectum two, throat two, stomach three, and one each of kidney, bladder, colon, pancreas, parotid, ovary, superior maxilla, abdomen, pelvis, tumour (died in cancer hospital), and "cancer" only, without locality, 30 cases. From these figures we arrive at the curious and unexpected conclusion that it is from cancer of the uterus chiefly that Jews are especially free. Taking, however, all forms of cancer, they are nevertheless subject to it as compared with the general population of London in the proportion only of 10·8 to 37·0—i.e., they are a little more than a quarter as liable to the disease as is the general population of London. In the two complete years, 1899 and 1900, the total deaths were 3798 from all causes, and of these 41 were from cancer, which gives one death in every 92 amongst the Jews, comparing with one in every 22 in the general population in 1896. We may take this in another way. The present mean Jewish population of London is said by the best authorities to be 105,000. Of these 100,000 are connected with the United Synagogues, and 5000 to 6000 are outside this Union. Out of this 100,000 41 died from cancer in the two years 1899 and 1900. This gives a mortality of 20 per 100,000, contrasting with 71 per 100,000 in the general population. The same result, therefore, works out as when the deaths from cancer are contrasted with the total deaths.

Thanks to Dr. Henry Russell Andrews, Obstetric Registrar to the London Hospital, I have the following further figures and information. He writes: The total number of in-patients in the London Hospital in 1899 was 13,234, and in 1900 about 13,500. Jews and Jewesses and their children form about one-sixth of the total. This is not based on actual counting but, Dr. Andrews thinks, is quite sufficiently nearly correct to work upon. Quite one quarter are children under 16. In 1899 and 1900 there were 20 male and female Jews of all ages as in-patients with cancer (not including cancer of the uterus) in the ordinary medical and surgical wards of the hospital, as against 286 Gentile males and females of all ages—that is, one cancerous Jew to 292 cancerous Gentiles. The proportion of total Jewish in-patients to Gentile in-patients, calculated on the basis of 6 per cent., would, however, be one Jew to every 162 Gentiles. So that from all possible sources of information on this subject, and calculated in every way possible, it always comes out that the Jews are much less subject to cancer than we are and that they are especially free from cancer of the uterus.

I should like it to be distinctly understood that my argument does not rest upon this question about the Jews but upon other and stronger grounds. The idea, however, was originated in my mind by the comparative immunity of the Jews.

I am, Sirs, yours faithfully.

Leeds, Dec. 13th, 1901.

JAMES BRAITHWAITE.

### A DANGEROUS PRINCIPLE.

To the Editors of THE LANCET.

SIRS.—On Feb. 25th, 1901, I made personal application to the registrar of the Royal College of Surgeons in Ireland for a copy of their by-laws for the purpose of ascertaining did these in any way bear upon the following provision in the charters of 1844 and 1885:—

And the examiners or any number of them declared by the by-law to be competent to transact business as a court of examiners shall in the presence of the President or in his absence of the Vice-President and two or more members of the council examine any candidate for a Fellowship.

Upon that occasion I was informed that the by-laws were

<sup>1</sup> THE LANCET, Dec. 7th, 1901, p. 1573.

being printed. On July 10th I wrote to the secretary of the council of the College, and was informed that when the by-laws were printed I could have a copy. Again on Nov. 21st I wrote in reference to the delay, and was informed that the council declined to give me a copy of the by-laws by advice of their solicitor. Having regard to the penal powers over its Licentiates possessed by the corporate surgical body concerned and to the dangerous principle now laid down by the President, Vice-President, and council of the Royal College of Surgeons in Ireland that they can withhold their by-laws from a Licentiate on the grounds of legal expediency, I beg space to lay this case before the profession through your valued journal.

Dec. 17th, 1901.

I am, Sirs, yours faithfully,

S. WESLEY WILSON.

## THE QUESTION OF FEMALE MEDICAL RESIDENTS IN GENERAL HOSPITALS.

*To the Editors of THE LANCET.*

SIRS,—Reflecting upon what is taking place at Macclesfield, Stockton, and other places in connexion with the employment of lady doctors in hospitals and infirmaries, it has struck me that some decided and clear guidance is needed for the professional and public mind from the leading organs of the medical press. I have myself no prejudice at all against the study of medicine or even surgery by those of the female sex who are well qualified for it by the excellence of their character and education, provided that it leads them to work in suitable channels and does not from its nature demoralise and unsex them. It does appear to me that the delicacy and refinement of mind which constitutes so great a charm and which one always expects to find in every cultivated and modest young lady is hardly compatible with promiscuous mixture with the young house surgeons in our hospitals and small infirmaries or with attendance upon the injuries and diseases of adults of the male sex. The finer sensibilities of her nature must be blunted and soon sacrificed for all time when she can view without a shudder the call to treat venereal diseases and pass catheters, for example, for adult males. And what must be thought of the individual young lady who would desire to seek such occupation? I say nothing of the feelings of her male patients who are to be subjected to such an outrage upon common decency. The retort may be made that women have to submit to similar services from the opposite sex, therefore why not the men. There is a great distinction. For centuries men have in the main carried on this work, and there can be no question that they have gained the confidence and good will to an extraordinary degree of the great bulk of their female patients. The lady doctors will have to work hard to establish themselves even in an equal degree of trust from their own sex, and as time goes on they may perhaps succeed in doing so. But in mixing themselves up with the treatment of diseases of men it seems as though they would be likely to defeat their own object, as it shows a coarseness of mental fibre that men would scarcely be found to tolerate and the more refined minds of their own sex would certainly condemn. The employment of these young ladies in the women's and children's wards of hospitals when they possess the requisite skill appears to rest upon an entirely different foundation, and may under some circumstances be preferred. There is a practical difficulty to be overcome in infirmaries doing all kinds of work and employing two or three house surgeons. The senior house surgeon is in confidential relation with the managing board and with the whole of the medical staff of the institution; he requires his own room and it is necessary that he should have it to himself. The other two will often share their room together. Imagine a young fellow of 24 and a young lady of 23 thus thrown together in such intimate daily association. This is no imaginary picture. At an infirmary some years ago a very highly qualified and experienced surgeon was elected as second house surgeon and at the same time a young lady as his junior. The two junior house surgeons had previously been accustomed to join at their sitting-room, and therefore when the gentleman was elected he naturally wished to know whether it was expected that the same arrangement would be continued. When told that it would he immediately threw up the appointment. He said, what would his mother say! The lady made no difficulty, but expressed her willingness to accept the position. Afterwards the good sense of the board prevailed, and when another election took place shortly after separate rooms were arranged with considerable addition of expense and discomfort. In small general infirmaries

it is frequently necessary for the house surgeons to interchange duties in the unavoidable absences of their colleagues, so that it becomes highly inexpedient and unpractical to appoint those who cannot when required take up the work in proper sequence. Where there are separate departments for children and women and no work is required amongst male adults, either as in-patients or out-patients, the circumstances are materially modified, and it then becomes a question of expediency and convenience as to housing and living, rather than of propriety and general decency.

I am, Sirs, yours faithfully,

Dec. 12th, 1901.

X.

## PUBLIC HEALTH APPOINTMENTS.

*To the Editors of THE LANCET.*

SIRS,—Your readers will be aware that after this month all applicants for appointments in the public health service will require either to possess a special diploma or to have been similarly engaged during the past three years. Candidates registered before Jan. 1st, 1890, are exempt from special regulations, but I gather that the examination is of such a nature as to entail a special and protracted course of bacteriological and chemical laboratory instruction. Candidates registered since Jan. 1st, 1890, must submit entirely to the new regulations as to course of instruction, pupilage, &c.

Under these circumstances it appears to me that of the many hundreds qualified during the last 10 years only a favoured few, possessed of both money and time, can ever become medical officers of health unless they already hold that distinction. I am among those registered before 1890 and have held office as medical officer of health but not during the last three years. Though I am exempt from the strict regulations, still the examination is almost prohibitive, if my information be correct. Are all, except those recently qualified and so able to become diplomates before settling down to be debarred from holding these important offices? What I really wish to know is whether any diploma is within reasonable reach of a busy practitioner, and whether, considering that the new regulations must limit the number of applicants, the field offers sufficiently bright prospects to entice entry; or are all these posts to be left for the future to the young and recently qualified man? I shall be extremely grateful for any advice from yourselves and also from any of your readers.

I am, Sirs, yours faithfully,

Dec. 18th, 1901.

LATE M.O.H.

\* \* \* Our correspondent will do well to consult Section 18 of the Local Government Act, 1888, from which he will see that every medical officer of health appointed after Jan. 1st, 1892, to a district of 50,000 or more inhabitants must either possess a diploma of public health or have been during some three consecutive years prior to 1892 medical officer of health to a district containing at least 20,000 inhabitants, or have been for not less than three years on the staff of the Medical Department of the Local Government Board. If "Late M.O.H." wishes for a diploma of public health he must pass the examination, although, as he was registered before Jan. 1st, 1890, the regulations as to study do not apply to him. Whether or not the diploma is within reach of a busy practitioner will depend largely upon the scientific learning which such practitioner has had and whether the interval which has elapsed since such training is a long or short one. So, too, the prospects must depend largely upon his age and qualifications. We should advise him to procure some of the recent examination papers and to ascertain whether there is any laboratory near at hand where he could do some chemical and bacteriological work.—ED. L.

## MEDICAL OR LAY SECRETARIES TO HOSPITALS.

*To the Editors of THE LANCET.*

SIRS,—With reference to the letter appearing in THE LANCET of Dec. 14th, p. 1699, over the signature of Dr. F. Bushnell, might I be permitted the liberty of indicating the reason

why lay secretaries, having to deal with matters of organisation and finance purely and simply, of hospitals, sanatoriums, and similar institutions, are preferred to, and are more successful as such than, members of the medical profession? It is to be found in the "specialised knowledge" possessed by such lay secretaries which is not obtainable in the medical man, or if so obtainable it is the exception, not the rule. To fill adequately and satisfactorily such a position it is business acumen and organising ability which are required, not professional knowledge. The question as to "whether medical candidates for such posts could be obtained" does not fully express what is required: the question rather should be whether medical candidates having sufficient competence and experience in such special branch could be obtained—to which question there can be but one answer. I inclose my card.

I am, Sirs, yours faithfully.

Dec. 13th, 1901.

CHARTERED ACCOUNTANT.

## THE ORGANISATION OF THE PROFESSION.

(FROM OUR SPECIAL COMMISSIONER.)

### *The Workmen and the Consultants at Birmingham.—Important Statistics relating to Contract Work.*

WE have seen that the proposed formation of a Consultative Institute at Birmingham brought all grades of the profession together in a common effort to resist this attempt to introduce commercial methods into medical practice. That such an attempt should have been made at all constitutes a further proof of the degrading effects of cheap contract work. This is a phase of the question on which it is impossible to insist too much. The great difficulty throughout has been to convince the general public that their interests and the interests of the medical profession are identical. Over and over again medical men have been accused of simply endeavouring to increase their incomes. There is, on the contrary, no profession more willing to work, not only for inferior pay, but, for the genuine poor, gratuitously. The argument is that if those who could pay did pay, then medical practitioners could afford to give full and careful attention to patients who could not pay at all and to those who could only pay very small sums, such as a penny per week. But if a large proportion of the public who can afford the usual fees enrol themselves in medical aid organisations, then the general practitioner, being thus deprived of his paying patients, has to make up in quantity for what he loses in quality. He has to put on his list several thousand subscribers at a penny a week to make up for a hundred or so patients at 2s. 6d. a visit. But if quantity thus replaces quality in the category of his patients so inevitably does the character of the attendance given also partake of the nature of quantity rather than quality. This is degrading to the profession and in nowise satisfactory to the patient. Thus the impression has gained ground that the club medical officer is an inferior man and a desire for something better has arisen. It was this feeling that led a large body of working men in Birmingham to support the proposal to create a Consultative Institute. The movement derived much of its strength from the dissatisfaction felt against club practice. It was also in a measure due to the extraordinary ignorance which prevails as to the meaning of the term "consultant." According to the popular opinion a consultant holds a much higher qualification than the general practitioner; he is supposed to have gone through a longer and more elaborate training, to have passed more difficult examinations, and to be altogether much more efficient. At a large meeting which was held previously to the formation of the Consultative Institute the working-men speakers clearly showed that they were under the impression that a medical man was trained either as a general practitioner or else as a consultant; and, if the latter, that he could advise on any disease with equal knowledge.

One of the medical practitioners in Birmingham who has taken an active part in the recent agitation, when discussing this question with me, expressed the opinion that perhaps this impression had arisen at the ambulance classes. Some workmen who attended these courses imagined that the teacher did not know more than what he taught. Hence, when they had completed the course, some of the pupils were apt to classify themselves with their teacher, thinking they know as much

as he did; and, if this knowledge did not suffice, then both teacher and pupil must go to a consultant. The club medical officer has himself not infrequently helped to confirm this impression. To get rid of a tiresome patient he has been apt to advise him to go to the hospital, urging that the members of the hospital medical staff were so much more clever. The same has occurred in surgery cases, the club medical officer being anxious to avoid attending on patients who require more bandages than he can afford to give. Over and over again club patients are heard to say that their medical officer has candidly told them that he was not capable of attending such cases. Yet if these same patients had offered a 2s. 6d. fee he would have been just as ready to attend them as the consultant who claims a guinea. Again, the club medical officer suits the language he employs to his patients and describes their complaints by their popular names. The consultant, on the contrary, employs technical terms and the patient goes away with the impression that the consultant has discovered a new disease which has escaped the observation of the club medical officer who is but a general practitioner and is therefore supposed to be much less capable. One speaker at the general meeting mentioned above indignantly explained how his club medical officer had told him that he was suffering from dyspepsia, whereas a consultant had subsequently informed him that he was afflicted with gastric catarrh. Nor is the medicine given by the club medical officer held in any higher estimation. Several speakers held forth on the same occasion in deprecating terms about the club medical officers and their "stock" and "slop" mixtures. No one, not even Mr. Arthur Chamberlain, attempted to define what was meant by the term "consultant," but it was quite clear that the workmen wanted to have someone at their disposal to whom they could bring their medicine, who would smell the bottle, shake his head, and prescribe something better. They did not want a real consultant to meet their club medical officer and consult with him, but they wanted a sort of referee who would act as a check over him. They compared the general practitioner to the ordinary workman and thought that it was only right that a foreman should be set over him to keep him in order and to see that he did his work properly. The consultant was evidently destined to play the part of the foreman. He was to be held *in terrorem* over the much-maligned club medical officer. Nobody seemed to realise, and nobody was willing to explain, that such complaints as may be justifiable were due, not to any incapacity or inferior training on the part of the general practitioner, but to the system of contract work which compelled the club medical officer to do more work than could be properly accomplished in the time he could afford to give. What can be expected when the average remuneration for a consultation and for medicine only amounts to a few pence? It would in many instances be better if there was no payment at all, as there would then be no disguising the purely charitable character of the advice given. There would be fewer poor patients and more paying patients, and both categories would receive better attention, the general practitioner would not be overworked and could do his best for all alike, there would be better opportunities for the advancement of medical science, and the advantages reaped by the general public would be quite as great as those secured by the profession.

The great need of the moment is a better array of arguments that will help to place the public on the side of the profession—that will convince the patient that his interests are identical with those of his medical attendant. The money argument ought not to be the most effective. There are other and much higher considerations. Unfortunately, these latter are apt to soar over some people's heads. For this category of individuals Dr. E. D. Kirby, honorary secretary of the Birmingham and District General Medical Practitioners' Union, has collected some valuable statistics. They are not yet complete, as they only extend over a period of six months, and a larger experience may necessitate the altering of many of the figures given, but the general moral conveyed is likely to remain the same. The results obtained are totally unexpected and they reveal a new fact which may lead the public to look more closely into the system of contract work. As a rule the complaint is that the medical officer of a medical aid organisation is insufficiently paid, and the public generally have displayed a stoical indifference in regard to this grievance. Perhaps, however, this apathy may be somewhat

shaken if it can be shown that occasionally the grievance is the other way round, and that it is the public who pay too much. The figures collected relate to several Birmingham clubs and local branches of friendly societies and compare the receipts of the medical officers with the number of visits paid and consultations given during the six busiest months—January to June—of the year 1901. An appeal is made that similar statistics should be drawn up on a larger scale and for a more prolonged period. It is the club medical officers who alone can give such information. The statistics which have already been obtained show that there is an amazing difference in the scale of remuneration when it is compared with the actual work done. In some cases the amount suggested above was inadequate; but it is also made evident that in other instances the payment is more than necessary, so perhaps the public will take greater interest in the matter. The amount received in annual subscriptions has been divided into two parts. One-third of the sum has been allotted as fees or remuneration for visits made to patients in their own homes and the remaining two-thirds for consultations given at the medical officer's surgery. In both cases the medicines, bandages, &c., are included. Taking first the Manchester Unity of Oddfellows, it is found that 205 visits were paid and 656 consultations were given in the six months. Reckoned on the above principle, the payments made amounted to 1s. 1d. for each visit and 8½d. for each consultation. For the members of a club which had its headquarters in Cannon-street there were 97 visits at 6d. each and 287 consultations at 4d., but in another case there were 276 visits and 1104 consultations which brought in only 3d. and 1-95d. respectively. Another organisation, known as the Ebenezer, yielded for 109 visits about 1s. 11d. each and for 473 consultations about 9d. each. Other figures show 2s. 4½d. per visit and 7d. per consultation. One medical officer records 377 visits working out at an average of 2s. 3d. each, and 2886 consultations at 7d. each, and another medical officer calculates that he received 2s. 9d. per visit and 11d. per consultation. On the other hand, the Union Provident for 432 consultations and 63 visits yielded only 2d. and 7d. respectively. The Birmingham Mutual Old Age Society for 34 visits and 133 consultations showed an average of 2s. 1d. and 1s. 0½d.; and two courts of the Ancient Order of Foresters for 62 visits and 281 consultations paid as much as 2s. 10½d. per visit and 1s. 7½d. per consultation, which is a little more than what is generally considered the minimum fee. But the most interesting point is that while the scale of remuneration is frequently very inadequate, it is now and then very much more than necessary and the patients would be far better off if they selected their own medical adviser and paid him the usual fees. Thus there is in Birmingham a small society consisting for the most part of young men. Only six visits were necessary during the six months and consequently these brought in an average of 12s. 1d. per visit. There were, however, 102 consultations and for these the average was only 1s. 5d. If we add 1d. to each of these consultations, to bring them up to the 1s. 6d. minimum, this makes 8s. 6d., and this amount we should deduct from the 72s. 6d. paid for the six visits, and there would then remain 64s. for the six visits, or 10s. 8d. per visit. If the members had paid 2s. 6d., the minimum fee per visit, this would have been 15s.; and deducting this sum from the 64s. there remains 49s. Therefore the members could have paid the minimum fees of 1s. 6d. and of 2s. 6d. and yet have saved 49s. out of a total expenditure of 217s. In this case, therefore, the members of the club were absolute losers. They could not choose their medical adviser, they had to accept the services of their club medical officer whether they liked him or not, and they paid him more than if they had sought medical advice in the ordinary manner. In another instance the amount paid per visit was 5s., but the average payment per consultation was only 7½d., so that the excess on one side is counterbalanced by the deficiency on the other side.

There is no difficulty in accounting for all these discrepancies. The remuneration does not depend on the amount paid but on the physical condition of the subscribers. This is an all-important consideration, for it clearly shows that no general rate of payment is applicable. For instance, it is thought absolutely scandalous to accept clubs at 2s. 6d. per head per annum, yet there are some clubs that pay very much better at this rate than other clubs where the members subscribe 4s. 4d. or even 5s. each. This is especially the case with seafaring populations. At Dundee crews engaged in whale-fishing only

pay 2s. 6d. per head per annum, but as they are away for at least half the year this is equivalent to a payment of 5s. a year for persons who are on land all the time. Indeed, this applies to a certain category of workmen whose homes are in Birmingham but who are constantly being sent to work in other parts of the country. Then, again, if a new club is formed consisting of young members they will need very little medical attendance, while, on the other hand, clubs of long standing whose original members have grown old require a great deal. The mistake has been made of comparing members of a club with the general population, whereas it would suffice if young men paid 2s. 6d. a year, though perhaps 10s. a year would not be enough for the old men. Of course, if the young and the old, the healthy and the weak, were mingled in the same proportion as they exist in the population at large it might be said that a general average could be struck, but this is not the case—the figures dealt with above relate only to adult males and the discrepancies would be infinitely greater if women and children were introduced. Thus, to give yet another example, the medical officer of lodges or branches of the Oddfellows, of the Unitarian Brotherhood, of the Rechabites, and of the Gas Workers' Union explains that each of these societies pay 4s. per head per annum. This brings him in an average of 1s. 2d. per visit and 7½d. per consultation. On the other hand, a society that pays only 3s. per head per annum yields 1s. 6½d. per visit and 8½d. per consultation, while a smaller lodge, which also only pays 3s. per annum, works out at 5s. the visit and 9d. the consultation. In the face of such figures it is absolutely impossible to lay down a general rule. To obtain anything like a financial equilibrium it would be necessary that a young society should appoint a young medical officer, that this medical officer should never sever his connexion with the society, and that he should live as long as its young members. Then the medical officer would have an easy time of it during the earlier period, to be counterbalanced by more pressing work as he became older and felt a growing need of rest. His remuneration, of course, would be the same throughout. The only other way out of the difficulty would be to introduce a sufficient quantity of new and young members into the old societies, but the figures given above clearly prove that this is not done, at least to a sufficient extent. It will be seen, therefore, that the whole system of contract work requires to be studied anew and that an increase, even a considerable increase, of the subscriptions paid will not meet the difficulty. Sometimes the lowest pay is the most remunerative when compared with the work actually done. It will be necessary to find a new combination.

(To be continued.)

## MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

### *Memorial to the late Professor Thomas Jones.*

ON Dec. 11th a bronze medallion portrait and a brass tablet which have been placed in Owens College Medical School in memory of the late Professor "Tom" Jones were unveiled in the presence of a large number of students and friends. The memorial tablet also bears the names of Mr. W. Davies, Mr. J. C. Eames, and Mr. H. Aldred who died in South Africa—four valuable lives given to their country from Owens College. Nearly £1000 were subscribed by 275 friends, which sum, as Professor G. A. Wright said, might have been largely increased if a public appeal had been made. In addition to the medallion and tablet a sum of £852 14s. was handed to the college authorities for the foundation of an exhibition in anatomy. Eloquent testimony was given to the respect and affection felt for the late Professor Jones.

### *Stockport Infirmary.*

The harmony existing between the Stockport Infirmary board and the medical staff contrasts pleasantly with the troubled state of things at Macclesfield in the same county. At a meeting of the board on Dec. 11th a letter was read from the honorary staff presenting an installation of the x ray apparatus which has been erected at the infirmary. At the same time the honorary medical board expressed their pleasure at the harmonious relations which had always existed between the board of management and themselves. Colonel Howard, the chairman, in moving a vote of thanks

to the staff, said that they had before shown their generosity by the presentation of an operating-room.

#### *Manchester Companies Volunteer Medical Staff Corps.*

An interesting event took place in Manchester on Dec. 3rd, when a dinner, presided over by Surgeon-Lieutenant-Colonel W. Coates, was given in honour of the First Service Company of the Manchester Companies Volunteer Medical Staff Corps who have recently returned from South Africa. Mr. Walter Whitehead—or, as he should here be styled, Surgeon-Colonel Walter Whitehead—spoke warmly of the great sacrifice made by Captain Smith in going to South Africa when his seniority entitled him to a certain appointment at the Royal Infirmary and said that he thought he should receive some recognition of the excellent services he had rendered. Captain Smith said that at Bloemfontein the orderlies were for some time doing duty for 36 hours out of 48, and although the work was of a kind not altogether congenial to them he was sure that, if required, they would be willing to go and do similar work again. It was stated that the Medical Staff Corps sent out more men in proportion to their strength than any other arm of the service. A smoking concert was afterwards held and the annual prizes were distributed by Surgeon-Colonel Whitehead.

#### *Manchester Ear Hospital.*

Sir W. H. Houldsworth, M.P., presided over the annual meeting of the Manchester Ear Hospital held on Dec. 11th. During the year 202 in-patients had been treated and a large number of operations had been performed, while the out-patients had numbered 2438. Alterations and furniture had cost £250, of which sum the committee subscribed £125 19s. Hospitals are like empires, every extension involves increased work and greater expenditure. Last year the latter exceeded the income by over £87, and an appeal was made for an addition of £100 to the annual income. There is no doubt of the great good done by the Ear Hospital, and the people of the Manchester district will surely find the means asked for.

Dec. 17th.

## WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

#### *Cardiff Isolation Hospital.*

In his last quarterly report the medical officer of health of Cardiff (Dr. E. Walford) draws the attention of the corporation to the necessity for enlarging the isolation hospital. This institution at present has accommodation, upon the Local Government Board basis of 2000 cubic feet for each patient, for 116 patients in six ward pavilions. Three of these pavilions have been in occupation only about a year and the remainder about six years. With the erection of three more pavilions, each for 22 patients, there would only be accommodation for 182 patients—none too much in view of the large number of working people who live in the town and of the readiness with which they avail themselves of the advantages of the hospital. The population of Cardiff at the last census was 164,000. Small-pox patients are now isolated in iron buildings situated upon land immediately adjoining the permanent hospital and Dr. Walford advises that a more remote site should be obtained upon which a permanent structure could be built. He expresses the opinion, also, that as the majority of cases of the disease come from vessels in the port the expense of a small-pox hospital should be borne by the port sanitary authority.

#### *Gratuitous Distribution of Antitoxin.*

Upon the recommendation of the medical officer of health the Neath Rural District Council has decided to supply antitoxin gratuitously to medical practitioners living in those portions of the district where diphtheria is prevalent.

#### *Prevention of Tuberculosis.*

At a public meeting held at Haverfordwest on Dec. 13th a sub-branch of the South Wales and Monmouthshire Branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis was formed for the counties of Pembrokeshire, Cardiganshire, and Carmarthenshire. Dr. Douglas A. Reid, medical officer of health of Tenby, was elected secretary, and the executive committee were instructed to take into early consideration the desirability of erecting a sanatorium for the open-air treatment of consumption and a sanatorium for the treatment of tuberculous diseases in children.

#### *Water-supply of Bath.*

Until the last few weeks the ordinary constant supply of water to the city of Bath has not been interrupted, but the absence of any considerable amount of rain in October necessitated careful husbanding of the water in the reservoirs and there was no supply during a few hours daily. The average rainfall in Bath during the past 41 years in October and November was six inches, but during the same months in this year it was less than two inches. Since Dec. 5th the yield of the springs has improved considerably and it is anticipated that there is now no likelihood of the supply again running short.

#### *Coroners and Medical Men.*

On Dec. 9th an inquest was held at Bussage, Gloucestershire, upon the body of a man, aged 47 years, who died from the effects of a bicycle accident which had occurred on the previous day. A local medical man who was sent for after the accident gave a certificate in which death was stated to be due to a fractured skull, but he refused to attend the inquest unless he had a written order. The coroner said that he ought to have been present, adding that the death certificate was useless and that it was well known that medical men were not entitled to give certificates in cases of this kind, as the registrar would not accept them but would refer to the coroner. The jury returned a verdict of "Accidental death."

#### *Proposed National Museum for Wales.*

On Dec. 10th at Cardiff a deputation waited upon the county council with a view to inducing them to take up the matter of a national museum for Wales. It was urged that the museum committee should be allowed to call to their assistance outside aid and that the designation of the Cardiff Museum should be altered, seeing that the institution was doing a national work, and that its name should indicate its real nature. Eventually the matter was referred to a committee.

Dec. 16th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

#### *University of Glasgow.*

At a meeting of the University Court held on Dec. 12th the Finance Committee submitted a statement dealing with a report of the senate on the proposed changes in the scope of the chair of natural history. Hitherto the professor of this subject has had the responsibility of teaching both zoology and geology and Dr. Young's resignation is to be made the opportunity of establishing a scheme which always had his hearty support—namely, the institution of two distinct chairs. It has been announced that the Bellahouston trustees are prepared to provide £6000 towards the foundation of a chair of geology. The committee recommended that application be made to the Carnegie trust for the balance of the sum required and this suggestion was accepted by the court. The following appointments to examinerships are announced: Dr. Ebenezer Duncan in medicine and clinical medicine, Mr. Sydney Jones in surgery and clinical surgery, Dr. R. Barclay Ness in materia medica and therapeutics, Mr. Malcolm Laurie in zoology, and Mr. D. R. Boyd in chemistry.—At a recent semi-public function in Glasgow Principal R. H. Story, in replying to the toast of "The University," took occasion to discuss several academic questions of current interest. Dealing with the appeal for funds for further extensions of the college he said it was somewhat unfortunate that after 30 years the splendid buildings at Gilmourhill should be found inadequate. This result was due to two causes—first, that Sir Gilbert Scott in designing the buildings had thought more of architectural effect than of the demands of modern science, and, secondly, that the number of students, more especially on the scientific side, had so greatly increased. The principal urged the claim of the university to public support and argued that Mr. Carnegie's generosity had by no means solved all their financial problems. He expressed the opinion that the devotion of such a large sum of money to the payment of fees had been a great mistake and that many who had no claim to such assistance were availing themselves of the benefits of the gift. If university education were to be made free the task should be undertaken by the Government and should include the whole of the students. Principal Story also

referred to the criticism which had been passed in certain ultra-Protestant quarters on the action of the university authorities in sending a letter to the Pope in connexion with the recent celebration of the ninth jubilee of the university. He scoffed at the suggestion that such a letter was an indication of Romanising tendencies and described it as a mere courtesy to the direct successor of Pope Nicholas VI., to whose Bull the university owed its existence.—A sign of the times may perhaps be detected in the announcement that a course of six lectures on the Outlines of Local Government in Scotland is to be delivered in connexion with the class of political economy by Miss Mabel Atkinson, M.A.

#### *Glasgow Central Dispensary.*

At a meeting of the directors of this institution held on Dec. 15th the following appointments were made: Dr. F. J. Charteris to be physician, Dr. George Jubb to be assistant physician, and Dr. John Gordon to be surgeon in the department of urinary diseases.

Dec. 17th.

### IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

#### *The Smyth Fund.*

THE contributions to the Belfast branch of the fund for the widow and family of the late Mr. W. Smyth of Burton Port, co. Donegal, amount to over £800.

#### *Royal College of Surgeons in Ireland: New Regulations for Academical Costume.*

The general body of the Fellows are authorised to wear a black stuff Master of Arts gown, faced with a St. Patrick's blue Irish poplin border, five inches in width, narrowing round the collar behind and extending to each end of the gown in front. Inside the blue poplin there shall be a crimson Irish poplin lining, five inches in width, and of similar extent to the blue. A black velvet college cap with St. Patrick's blue and crimson tassel. This gown and cap may be worn at all public functions, college ceremonials, state and civic public meetings: and on all occasions when academical costume is worn by the general body of the Fellows of the Royal College of Surgeons of England and of the Royal College of Surgeons, Edinburgh.

#### *County Antrim Infirmary.*

At a meeting of the board of management of the County Antrim Infirmary, held in Lisburn on Dec. 13th, the chairman (Mr. J. M. Barbour) announced that his wife had invested £1000 in Northern Counties debenture stock for the use of the County Antrim Infirmary, the condition of the gift being that the interest should be paid to the County Antrim Infirmary so long as it remained in Lisburn, but in the event of that institution being removed from that town then the money would be devoted to some local charity for the benefit of Hilden and Lisburn. A very cordial vote of thanks was passed to Mrs. Barbour for her very generous gift.

#### *Dinner to Professor J. Lorrain Smith.*

A dinner by his old pupils was given to Dr. J. Lorrain Smith in Ye Old Castle Restaurant, Belfast, on Dec. 10th on his being appointed professor of pathology in Queen's College, Belfast. Between 50 and 60 persons were present, including the President of the North of Ireland branch of the British Medical Association, the President of the Ulster Medical Society, the President of Queen's College, Belfast, and Sir James Musgrave, D.L. (the founder of the chair), all of whom were invited guests. Professor J. Symington presided and the principal toast of the evening, which was very cordially received, was "The New Professor of Pathology," to which Dr. Smith replied.

#### *The Poor-Law System.*

A meeting was held in the Belfast Chamber of Commerce on Dec. 13th for the purpose of establishing an association for the province of Ulster which shall have for its objects the holding of conferences and the taking of steps to bring about amendments in the Poor-laws and in their administration. It was decided to form an Ulster Poor-law Conference Association, the objects being to promote united action on the part of Poor-law boards and other public bodies and persons interested in Poor-law administration in the province of

Ulster and throughout Ireland; to procure such alterations in the law and in the regulations of the Local Government Board and such improvements in Poor-law administration as from time to time may be required; to promote the holding of conferences on Poor-law subjects; and to endeavour to bring about the assimilation of the Irish to the English law which gives a legal status to such conferences. A representative council of ladies and gentlemen interested in Poor-law reform was appointed to control and manage the affairs of the association.

#### *Death of Two Ulster Medical Men.*

I regret to announce the death of two Ulster medical men—Dr. Samuel H. Campbell of Portrush, co. Antrim, and Mr. John S. Ward of Lisburn, co. Antrim. The former gentleman was of advanced years, as he graduated M.D. of Glasgow in 1844. For a long time he was medical officer of the Portrush Dispensary and Admiralty surgeon, and he practised for many years in the well-known Irish summer retreat, Portrush, where he died on Dec. 12th. Mr. John S. Ward was an Englishman who came to Lisburn as a young man, to teach in the Ulster Provincial School, an institution belonging to the Society of Friends, of which he was a member. Later, after his marriage, he entered the business of pharmaceutical chemist and subsequently, in 1884 (after studying in Belfast and Edinburgh), he obtained the qualification of the Royal College of Physicians, Edinburgh. For a time he was assistant surgeon and apothecary to the County Antrim Infirmary, Lisburn, and he was surgeon to the Brookfield Agricultural School, Lisburn. Mr. Ward had been in his usual health on Sunday, Dec. 15th, when he attended the service in the meeting-house of the Society of Friends at Lisburn. He died suddenly the next morning from cardiac failure. Mr. Ward enjoyed the respect and esteem of a large circle of friends. He was buried at Lambeg on the 18th. He leaves a widow, but no family.

#### *Royal Victoria Hospital, Belfast.*

Lieutenant-Colonel Andrew Deane, I.M.S. (retired), has been appointed Superintendent of the Royal Victoria Hospital, Belfast.

Dec. 18th.

### PARIS.

(FROM OUR OWN CORRESPONDENT.)

#### *Lumbar Puncture as a Means of Diagnosis in Fracture of the Base of the Skull.*

At the meeting of the Society of Surgery held on Dec. 4th M. Poirier related the case of a patient who had been admitted to hospital under his care on Sept. 16th suffering from the sequelæ of a fall on the nape of the neck. He complained of pains in the head and of constant vomiting and had a wound of the skin in the occipital region. His temperature was 37.2° C. and his pulse was 110. On the day after admission he became semi-comatose and at times gave the hydrocephalic cry, but no paralysis was present. Cerebral meningitis was suspected. The *interne* of the ward performed lumbar puncture and a jet of cerebro-spinal fluid tinged with blood spurted out. Between 30 and 40 grammes of fluid were drawn off. This slight operation had a prompt and astonishing effect. Within a few hours the coma, the vomiting, and the headache had disappeared, and on the following day (the fourth since the accident) the patient talked about leaving the hospital. He continued to improve and, as if to confirm the diagnosis, paralysis of the right internal rectus and conjunctival ecchymoses developed in each eye. He left the hospital, although advised not to do so, on the eleventh day and was not seen again. In this case the diagnosis was cleared up by the result of the lumbar puncture and, moreover, the evacuation of the fluid seemed to have a remarkably beneficial effect. M. Rochard cited a case, that of a child with severe cranial injuries, in whom he had brought about rapid and marked relief by the withdrawal of 20 cubic centimetres of cerebro-spinal fluid. He also mentioned another case of fracture of the skull in which he performed lumbar puncture for the relief of persistent headache 15 days after the accident with marked relief. M. Tuffier remarked that he had already drawn the attention of the society to the value of lumbar puncture in fractures of the skull as a means both of diagnosis and treatment. He thought that the fluid should be collected in three separate tubes so as to make

certain that the red colour was that of the fluid itself and did not come from puncture of a spinal vein. The cerebro-spinal fluid might vary from a bright red to pink or yellow and contained no red corpuscles.

#### *Election to the Academy of Medicine.*

Dr. Albert Josias, physician to the Bretonneau Hospital, has just been elected a member of the Academy of Medicine. He is one of the few Paris hospital physicians who has turned his attention to the all-important subject of state medicine. He took his doctor's degree in 1881, his thesis being upon the subject of Typhoid Fever in Elderly Persons, the matter for which he had collected at the Tenon Hospital in the wards of Dr. Rendu. After serving as a prison surgeon in the central prison infirmary of the Seine, where he worked through the cholera epidemic of 1884 and the small-pox epidemic of 1887, he was made physician in succession to the Pitié, the old Trousseau, and the Bretonneau Hospitals. He is now consulting physician to the veterinary school at Alfort.

#### *Accidents to Workmen during the Exhibition of 1900.*

M. Wagner has written a thesis upon accidents occurring to workmen during the Exhibition of 1900. These figures deal mainly with the year 1899, in which year, of course, the works were in progress. During that year the Champs Elysées Station alone treated 1171 cases of accident and the Invalides Station 572. Eight deaths occurred, three from fracture of the skull, one from fracture of the spine, one from fracture of the pelvis, two from severe abdominal contusions, and one from drowning in the Seine. This is a high proportion of deaths seeing that the figures are those for one year only. Another table gives the figures of serious surgical accidents occurring in various works from the year 1896 to July 1st, 1901. There were 249 cases of injury to the eye and 152 fractures, of which 23 were cases of fractured ribs, 21 were of fractured fingers, 16 were fractures of the radius, and 16 were cases of Pott's fracture. These figures show that serious fractures like those of the skull or of the pelvis are by no means common. M. Wagner unfortunately gives no details of treatment. It is to be hoped that when the full medical report of the Exhibition is published details of treatment and of the after-progress of the cases will be given.

#### *Another Medical Play.*

The French stage continues to occupy itself more and more with medical subjects. One house follows another in producing plays of this description, the latest to do so being the Renaissance Theatre. Here there has just been given a new play by M. Masson Forestier, called *The Country Doctor*. It is a story of disillusion. A young medical man takes over a practice in a country district which, however, does not offer very great advantages. The other practitioner in the village is an elderly *officier de santé*, by name Palfrène, and most of the well-to-do patients much prefer "old Doctor Palfrène" to the young newcomer. Palfrène falls ill from pneumonia and his wife seeks the aid of the young practitioner, whose name is Valadier. He treats his patient after the latest fashion and among other things prescribes cold baths. This is too much for Madame Palfrène, who says that her husband shall be treated as he treats his own patients—namely, by bleeding. Valadier is obliged to agree under protest, for he knows that the Paris professor who has been called into consultation and who is just on the point of arriving, always argued that this method of treatment was quite out-of-date. When he arrives he congratulates his young colleague, for Palfrène is quite recovered, thanks to the bleeding. Valadier is much puzzled by this and comes to the conclusion that it is quite possible that in future he will prefer old modes of treatment to new.

#### *Conjunctivitis due to a Specific Bacillus.*

DR. AUGUST COLOMB of Geneva has published a study of 97 new cases of conjunctivitis due to infection from a diplo-bacillus. Three years ago Dr. Chauvel of Paris, speaking in the name of the Academy of Medicine, remained very sceptical as to the existence of such a disease and the specificity claimed for it by Dr. Morax. He issued a warning against the multiplication of the number of varieties of

conjunctivitis, but facts—stubborn things—have proved the claims of Dr. Morax. The studies of Dr. Gonin, of Dr. Colomb, and especially of Dr. zur Nedden of Bonn, who published a series of 500 cases, have decided the question. Dr. Colomb now contributes nearly 100 new cases casually, not systematically, collected during the last two years, thus proving that this specific conjunctivitis is very common. The examination of the secretion was made directly on the cover-glass and if possible corroborated by cultures in suitable mediums (bouillon, glycerine-agar, and Löffler serum). 46 cases showed the symptoms of subacute or chronic conjunctivitis, 27 of blepharo-conjunctivitis especially localised at the borders, and 24 cases combined conjunctivitis with acute blepharo-conjunctivitis. Dr. zur Nedden collected his 500 cases in 18 months and calls the disease very widespread. In chronic cases the staphylococcus aureus was also present. Dr. Colomb especially mentions in detail eight observations concerning children under one year of age observed by him and other medical men. Inoculation proves the contagiousness of the affection and infections in families (36 cases) go to prove this also. There is probably direct transmission from one mucous membrane to another. The bacillus keeps alive some days in an aseptic tube, though exposed to light, and retains its virulence; thus the mode of transmission through handkerchiefs and towels and similar articles is possible and probable. The bacillus is easily stained with violet of gentian, the counter-proof of Gram being necessary. A magnifying power of 800 is desirable to ensure exact diagnosis.

#### *Koplik's Plaques in Measles.*

Dr. Emil Feer of Basle, *privat-docent*, has made observations on 200 cases of measles. In 89 per cent. of all these cases the Koplik plaques were to be seen from one to three days before the appearance of the skin eruption. As the patchy discolouring of the mucous membranes in the fauces precedes the skin eruption by one day only, Koplik's plaques ensure prompter diagnosis. Examination by direct light is desirable as one can easily overlook the plaques in artificial light if they are small and very localised. They consist often of very minute white or bluish-white spots on the surface of the mucous membrane of the cheek, generally opposite the molars. They are often to be seen more distinctly when they have a tiny hyperæmic border. They never occur in any other disease, especially not in German measles (*rötheln*) according to Dr. Feer's exact examinations in 37 cases. Dr. Feer mentions Falkener's and Slawyk's studies on the subject which concur with his own, and says that Lorand found the plaques in 329 out of 349 cases, a percentage of 95. In some cases the diagnosis of measles in the incipient stage enables the medical man to make his diagnosis so soon that isolation proves of effect and the other children in the family escape infection. Such prophylactic measures must not be underrated as measles may prove very dangerous and sometimes fatal in young and feeble children.

### NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

#### *Proposed Changes in the United States Army Medical Department.*

IN this country, as in Great Britain, although to a lesser degree, there has been for a considerable time grave dissatisfaction with the manner in which the Army Medical Department is conducted. Major W. O. Owen, surgeon, United States Army, read recently before the Academy of Medicine at Cincinnati a paper which voiced the sentiments of the malcontents and which has provided food for discussions in medical and lay journals. The author wants legislation by Congress to allocate the responsibility for insanitary conditions among troops and to provide punishment for the fault. He would likewise give the right of self-government to the Medical Department with regard to the supervision and transportation of medical supplies. Major Owen holds that the Medical Department should have in its hands all matters relating to the sanitary care of troops, so that its authority should not be overruled, as is often the case, by the commanding officer. Major Owen's plea that the medical department of an army should have complete and independent control of those matters which directly appertain to it

has much to be urged in its favour. However, so drastic a plan is impracticable. A training in the principles of sanitation at the military schools of the country could effect nothing but good, and such a step is recommended by the *Medical Record* and other medical journals. It also seems to be the general opinion that Major Owen's argument that the Medical Department should control its own transport is right. Increased powers granted to the Medical Department would prevent the recurrence of the state of chaos which prevailed during the Spanish-American war so far as the forwarding of medical supplies was concerned, and for which the Medical Department was wrongly held accountable.

*Report of the Surgeon-General of the United States Navy for 1900.*

This report has just been issued and it states that the health of the Navy and Marine Corps for the calendar year 1900 was satisfactory, although there was a slight increase in the ratio of admissions to the sick list per 1000 of strength as compared with that for the previous year. The average strength of the active list for 1900 was 23,756. The total number of admissions from all causes was 18,936; of these 15,829 were for disease and 3107 for injury, giving ratios per 1000 of strength of 688.90 and 145.52. During the year there were 211 deaths, the death-rate per 1000 of forces being 8.88, divided as follows: for disease, 5.01; and for injury, 3.87. The admissions to the sick list during the year included 1699 cases of epidemic catarrh, 983 of malarial diseases, 963 of wounds, 902 of diarrhoeal affections, 828 of rheumatic affections, 336 of dengue, 246 of alcoholism, 195 of dysentery, 175 of typhoid fever, 160 of measles, 132 of mumps, 128 of heat stroke, 117 of pulmonary tuberculosis, 100 of organic heart disease, 99 of pneumonia, 40 of nephritis, 37 of rubella, 10 of small-pox, two of yellow fever, and one of bubonic plague. Epidemic catarrh was by far the most extensive and widespread complaint to attack the men of the United States Navy. The returns do not indicate that the unusual number of cases was due to conditions peculiar to the naval service, but rather that it was incident to a pandemic spread of the disease. Malarial affections were very common on the Asiatic and North Atlantic Stations. Typhoid fever was more prevalent than usual, especially in the tropics. Diarrhoeal affections on the whole were less than in former years, but dysentery caused a larger number of admissions than in 1899. Dengue was, as in previous years, especially prevalent at Cavite, but the attacks were generally mild in type, ending in complete recovery and usually in immunity to the disease. Of the 10 cases of small-pox reported five proved fatal.

*The Water-supply of New York.*

A question to be faced by the new municipality of New York is that of the water-supply. No fault can be found with the generosity of those who planned the reservoirs which at present provide New York with water so far as quantity is concerned, but the quality at certain periods of the year is altogether another matter. Although analysis has demonstrated that even when most turbid the metropolitan drinking-water does not contain bacilli particularly harmful to health, yet at the same time it is on occasions disagreeable, not to say nauseous. The remedy for this state of affairs, according to experts on the subject, is to provide an efficient system of sand filtration. Such a measure would necessitate the expenditure of an immense sum of money, but the gain to the city from a health point of view ought amply to justify the primary cost.

*Vaccination and Tetanus.*

A short time ago several cases of tetanus occurred in Camden, New Jersey. The anti-vaccinationists, inspired doubtless by the fact that tetanus in St. Louis has been recently traced to impure diphtheritic antitoxin, proclaimed that lockjaw in Camden was due to poisonous vaccination lymph. This allegation was seized upon by the sensational lay journals and much prejudice has been aroused against vaccination. However, the Camden Board of Health have made a report on the matter which utterly refutes the mischievous statements made by the opponents of vaccination. They made a thorough and exhaustive investigation into the case and came to the following conclusions: "The tetanus cases in Camden are to be explained on atmospheric and telluric conditions which have prevailed in Camden during the past six weeks. There has been a long period of dry weather with high winds, so that tetanus germs, which have their normal habitat in the earth, dust, dirt of stables, &c., have been

constantly distributed in the atmosphere. It is noticeable in all the cases after careful examination as to the cause that the wound had been exposed by the scab being knocked off or removed, or else the arm had been injured and infection resulted; frequently children scratched the vaccinated arm with their dirty finger-nails and infected the wound." It is satisfactory that proof has been brought to show that impure lymph was not the cause of the cases of tetanus in Camden and the report of the board of health of that town should tend to reassure the public as to the innocuousness of vaccination. At the same time the fatalities from tetanus in Camden proceeding indirectly from carelessness in guarding the wounds produced by vaccination should act as a warning and impress upon the minds of the vaccinated the need of carefully protecting such wounds.

## AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

*Proposed Hospital for Consumption for Sydney.*

A DEPUTATION of medical men and prominent citizens of Sydney recently waited on the Premier to ask the Government to establish a special hospital for the treatment of consumption. The Mayor of Sydney, Sir James Graham, M.D. Edin., who introduced the deputation, said they wanted done for consumptives what was done for other infectious people. At present consumptives, because infectious, could not be admitted into ordinary hospitals. What was wanted was a State institution, within easy access of the city, containing about 200 beds, where these patients could be sent and treated till they could, if found suitable, be sent to sanatoriums in the country, or if unsuitable cared for till they died. The cost would be about £50,000. The Premier said that he had every sympathy with the proposal and was anxious to avoid delay. He intended to erect a wooden building as a tentative arrangement at Long Bay and would ask Parliament to vote the necessary money on the Supplementary Estimates. The construction of more extensive buildings could be considered later.

*Prince Alfred Hospital Extension.*

The report of the Public Works Committee on the proposed additions to the Prince Alfred Hospital which was presented to Parliament confirmed the expediency of the proposal, provided the cost did not exceed £45,000 and that such alterations were made in the plans as to ensure improved ventilation and lighting. The plans prepared and approved by the hospital board had been condemned by private architects examined by the committee. The wings, in which were to be situated the new lecture-rooms and operating theatre, would prevent a considerable part of the southern side of the pavilion for patients getting the sun in winter, while on the western side the wards were unprotected from the extreme heat of the summer. The Government architect, while not agreeing with their criticisms as to the general design, admitted that several objections as to details were worthy of consideration and submitted an amended design for the educational portion of each pavilion which embodied several of the improvements suggested by the criticising architects.

*Municipal Sanitation in Sydney.*

The outbreak of the plague has stirred up the Sydney Municipal Council to considerable activity in sanitation, and with a medical mayor and a "reform" council great progress has been made. One of the first steps was the appointment of a city health officer, and that officer—Dr. W. G. Armstrong—recently detailed to a number of medical practitioners, invited by the mayor, the sanitary work accomplished. Sanitary inspectors, most of whom had passed the tests of the London Sanitary Institute, had been appointed and assigned to definite districts and had to inspect every house in their respective districts at least twice a year and to record every sanitary fact about each dwelling at each inspection. Where defect was found legal action was taken to remedy it. A special inspector had been told off to look after common lodging-houses and he had reported on over 1000, their sanitary condition showing much improvement as regards air-space, ventilation, and cleanliness. Active measures of disinfection had been carried out in cases of scarlet fever, diphtheria, and typhoid fever, the existence of which was reported in a routine

way. Disinfection of premises where phthisis had occurred was also carried into effect. Whenever a death from phthisis occurred the house was visited and disinfection was offered, but other houses could only be reached through the voluntary aid of the profession. Fumigation had been discarded as a tedious, clumsy, and unsatisfactory procedure, and instead all walls, floors, and furniture were sprayed with formalin, and all linen, bedding, &c., were soaked in a solution of corrosive sublimate, 1 in 1000.

*Students' Fees at the Melbourne Hospital.*

A deputation, representing the council of the Melbourne University, the faculty of medicine, and the honorary staff of the hospital, recently waited on the committee of the Melbourne Hospital and asked that the increase in fees charged to medical students from £5 to £20 should not be continued, as it was excessive and would drive students to other medical schools where the fees were lower and where, moreover, greater advantages were given for the fees paid. The committee at a subsequent meeting decided that the fees for the full undergraduate course should be £10 10s.

*Charge against a Medical Man.*

Dr. Frederick William Marshall, a medical practitioner, was on Oct. 3rd tried at the Sydney Criminal Court for having performed an alleged illegal operation on a young woman. The jury found him not guilty.

*Return of Dr. J. A. Dick.*

A public welcome of a most enthusiastic nature was accorded to Dr. J. Adam Dick, of the Army Medical Corps, who has just returned from 21 months' active service in South Africa. Dr. Dick was with Lord Roberts, General French, and General Clements, and was mentioned in Lord Roberts's first despatch for special and meritorious service. Colonel Fiaschi said that there was no more ardent or devoted medical man at the front than Dr. Dick. In the crowded hospitals, on the long marches, on the field under fire, Dr. Dick always did more than his duty.

*Obituary.*

The news of the sudden death of Mr. R. S. Bright, M.R.C.S. Eng., L.M., L.S.A., of Hobart, was received with universal regret and sorrow by the profession in Australia. Mr. Bright was President-elect of the next meeting of the Australasian Medical Congress to be held in Hobart in February next, and it will be very difficult to fill his place. Mr. Bright was born in London in 1835, and began to practise his profession in Hobart in 1859. He was the senior member of the honorary staff of the Hobart Hospital and was president of the medical section of the Royal Society of Tasmania. He had by far the largest practice in Tasmania and was held in universal esteem both for his high professional attainments and his personal qualities. He took a deep interest in art and literature and was a member of the committee of the Hobart Museum and Art Gallery. He died in harness. He had some affection of the heart and was attacked with a little bronchitis on Sunday, Oct. 27th, but carried out his professional duties as usual. Towards morning he became very weak and he died in his sleep at 9 A.M. on Monday, Oct. 28th.—I also regret to have to record the death of Mr. W. Lloyd Mathias of Darlington, Sydney, from pneumonia, at the early age of 37 years. Shortly after taking his qualifications of M.R.C.S. Eng. and L.R.C.P. Lond. he came to Sydney and entered into partnership with the late Dr. Kyngdon whom he subsequently succeeded. He was very popular both with the profession and the public.

Nov. 6th.

**DONATIONS AND BEQUESTS.**—Queen Charlotte's Hospital has received a grant of £100 from the Goldsmiths' Company and £10 10s. from the Salters' Company.—The Royal Dental Hospital, Leicester-square, has received £100 for the general maintenance fund and £100 for the new building fund from the Goldsmiths' Company, and £105 from an anonymous friend.—Under the will of the late Mr. Bernhard Charles Hirsch of Hampstead certain sums forming part of the residuary estate are left in trust to the following hospitals: to the North London Hospital for Consumption, £3000, and to the North-Eastern Hospital for Children, £1000. £1000 are also left for the endowment of a cot at the Great Ormond-street Hospital. The Prince of Wales's Hospital Fund will probably benefit to the amount of £25,000 or more.

## Obituary.

DAVID RITCHIE PEARSON, M.D. EDIN., M.R.C.S. ENG.

DAVID RITCHIE PEARSON, who died on Dec. 5th, near Rye, in Sussex, was the son of the late Major Pearson, of the Honourable East India Company, and was born in April, 1837, and educated at Madras College, St. Andrews, and Edinburgh University. In 1858 he was appointed assistant surgeon to the Rifle Brigade and served for two years in India. He settled in practice in Kensington in 1863, where he remained until his retirement in 1900. Dr. Pearson served as assistant surgeon in the Tower Hamlets Militia and the London Scottish Volunteers. He was for 35 years honorary physician to the National Industrial Home for Crippled Boys and worked hard on the managing committee of that institution. He also helped to found, and took great interest in, the Kensington Dispensary, of which for 25 years he was physician and a member of the medical board. He was consulting physician to the Industrial Institution for the Blind and to the Working Ladies' Guild. Dr. Pearson was a man of attractive personality, gentle, wise, and dignified, with a touch of old world courtesy. He never acquired a very large practice, and amongst his patients were a considerable number of people of gentle birth but little fortune who seemed to gravitate into his kind and sympathetic hands and always commanded his utmost efforts for their welfare. But rich and poor gained confidence from his steadfast character and skilful handling and his memory will be held in affection and respect by many friends and former patients.

Dr. Pearson contributed some thoughtful papers to the Pathological and Clinical Societies of London and to the *British Medical Journal*. He married in 1869 Jane, eldest daughter of Mr. James Rae of Phillimore-gardens, Kensington, who survives him, and has left a family of several children, of whom four are sons; one, Dr. Allan Pearson, is in the Army Medical Service, another is in the Royal Engineers, and two are in the Indian Civil Service.

JENKIN LLOYD, M.B., C.M. GLASC.

DR. JENKIN LLOYD of Bethesda, Carnarvonshire, died on Nov. 20th, at the age of 48 years, after an illness of only a few hours' duration. On the morning of that day he went out in his usual health, but returned at 11 A.M. feeling ill, soon passed into a state of unconsciousness and expired about 6 P.M. Dr. Lloyd was a native of Llanddeiniol, Cardiganshire, and received his medical education at Glasgow University, where he graduated as M.B. and C.M. in 1881. Returning to Wales he made his home in Blaenau Ffestiniog, but after some years he went to Bethesda as assistant to Dr. Hughes, ultimately becoming surgeon to the Bangor slate quarry. In 1891 he married the niece of Dr. Hughes, Miss Williams of Carnarvon, daughter of Ioan Mai, the well-known bard and *litterateur*. Dr. Lloyd was an ardent Welshman; he also had a reputation as an excellent bard and was a master of the difficult Welsh metres. His natural kindness of heart and sympathetic manner gained for him many friends, by whom he is much missed. The funeral took place on Nov. 23rd in Glanogwen Churchyard.

**DEATHS OF EMINENT FOREIGN MEDICAL MEN.**—The deaths of the following eminent foreign medical men are announced:—Dr. C. E. Stoner, Professor of Surgery in the Iowa College of Physicians and Surgeons.—Dr. Francisco Melendez y Herrera, Professor of Anatomy in the Cadiz Medical School.—Dr. Gouguenheim of Paris.—Dr. Jarvis S. Wight, Professor of Clinical Surgery in Long Island College Hospital, Brooklyn.—Dr. Mascara, Professor of Medical Pathology in the Manila Medical School.—Dr. N. Guardia, formerly Professor of Midwifery in the University of Caracas.—Dr. G. Chiarleoni, Professor of Midwifery in the Palermo Medical School.—Dr. F. de Castro, Professor of Medical Propeutics in the University of Rio de Janeiro.

## Medical News.

UNIVERSITY OF LONDON.—At examinations held recently the following candidates were successful:—

### M.B. EXAMINATION FOR HONOURS.

*Medicine*.—First Class: Alfred Ernest Jones (gold medal), University College; Henry Crew Keates, Guy's Hospital; John Henry Sheldon, Owens College and Manchester Royal Infirmary; Harold Weightman Sinclair, St. Thomas's Hospital; and Charles James Thomas, B.Sc. (scholarship and gold medal), St. Bartholomew's Hospital. Second Class: Carey Franklin Coombs, St. Mary's Hospital; Myer Coplans, Guy's Hospital; Robert Kelsall, Owens College and Manchester Royal Infirmary; and Albert Edward Thomas, St. Bartholomew's Hospital. Third Class: Ernest Gilbert Bark, Queen's and General Hospitals, Birmingham, and Birmingham University; William Henry Bowen, Guy's Hospital; John Charlton Briscoe, King's College; Ellen Mary Sharp, London (Royal Free Hospital) School of Medicine for Women; James Ernest Stratton, University College; and George Ernest Waugh, Cambridge University and University College.

*Obstetric Medicine*.—First Class: Alfred Ernest Jones (Scholarship and Gold Medal), University College; John Henry Sheldon, Owens College and Manchester Royal Infirmary; and Charles James Thomas, B.Sc. (gold medal), and Ernest Eric Young, St. Bartholomew's Hospital. Second Class: Olive Claydon, London (Royal Free Hospital) School of Medicine for Women; Carey Franklin Coombs, St. Mary's Hospital; Ellen Mary Sharp, London (Royal Free Hospital) School of Medicine for Women; Harold Weightman Sinclair, St. Thomas's Hospital; and William Henry Wynn, B.Sc., University and Queen's and General Hospital, Birmingham. Third Class: Arthur Edmunds, B.Sc., King's College; Robert Kelsall, Owens College and Manchester Royal Infirmary; and John Ford Northcott, Guy's Hospital.

*Forensic Medicine*.—First Class: Ellen Mary Sharp (scholarship and gold medal), London (Royal Free Hospital) School of Medicine for Women; and Albert Edward Thomas (gold medal), St. Bartholomew's Hospital. Second Class: Robert Ellis Roberts, B.Sc., St. Thomas's Hospital; and William Henry Wynn, B.Sc., University and Queen's and General Hospitals, Birmingham.

### B.S. EXAMINATION.

*First Division*.—Janet Mary Campbell, London (Royal Fever Hospital) School of Medicine for Women; Felix Bolton Carter, M.D., University College; Arthur Edmunds, B.Sc., King's College; Ernest Lewis Lilley, Charing Cross Hospital; Charles Archibald Scott Ridout, St. Bartholomew's Hospital; Thomas Copeland Savage, University College; and Ralph Paul Williams and W. Halliburton McMullen, King's College.

*Second Division*.—William Fielding Addey, University College; Kenneth Bush Alexander, Guy's Hospital; William Billington, Birmingham Medical School and King's College; Charles Henry Bullen, Birmingham Medical School; Adrian Caddy, St. George's Hospital; Katherine Chamberlain, London (Royal Free Hospital) School of Medicine for Women; Carey Franklin Coombs, St. Mary's Hospital; David Leighton Davies, University College; Herbert Charlton Jonas, St. Thomas's Hospital; Helena Gertrude Jones, London (Royal Free Hospital) School of Medicine for Women; Henry Crew Keates, Guy's Hospital; Robert Kelsall, Owens College and Manchester Royal Infirmary; Herbert James Marriage, St. Thomas's Hospital; Richard Rothwell Mowll, King's College; Frank Herbert Noko and William Trethowan Rowe, St. Bartholomew's Hospital; Douglas Wilberforce Smith, Guy's Hospital; William Lunsden Stuart, King's College; Kenneth Vincent Trubshaw, Guy's Hospital; Blanche Elinor Walters, Royal Free Hospital; Herbert Septimus Ward, Cardiff Medical School and St. Bartholomew's Hospital; Florence E. Willey, B.Sc., Louisa Woodcock, and Edith Louisa Young, London (Royal Free Hospital) School of Medicine for Women; and Ernest Eric Young, St. Bartholomew's Hospital.

N.B.—The foregoing lists, published for the convenience of candidates, are provisional only and are not final until the reports of the examiners shall have been confirmed by the Senate.

UNIVERSITY OF CAMBRIDGE.—At the examinations for medical and surgical degrees, Michaelmas term, the following candidates were successful:—

### FIRST EXAMINATION.

*Part I. Chemistry and Physics*.—G. D. Alexander, B.A., Caius; F. W. Argyle, St. John's; F. O. Arnold, Trinity; J. Barcroft, M.A., and H. Bowring, King's; P. E. Braham, Clare; J. P. Buckley, Trinity; H. V. Byatt-Byatt and B. P. Campbell, Clare; H. B. Carlyll, St. John's; R. C. Chance, Trinity; H. Chapple, St. John's; L. Colledge, Caius; A. F. Comyn, Pembroke; R. Crawford, Jesus; N. R. Cunningham, B.A., and G. H. Davy, Caius; A. T. Densham, St. John's; H. Dimock, Sidney Sussex; A. C. J. Milwin, Corpus Christi; F. S. Eschwege and A. W. Ewing, Christ's; N. M. Fergusson, Magdalene; H. B. H. Follett, Clare; L. A. Fothergill, Emmanuel; N. H. Gandhi, Caius; G. Graham, Trinity; B. Haigh, Caius; H. W. Hesse, Trinity Hall; F. S. Hewett, Caius; T. R. Hodgson, Christ's; G. Hoffmann, Caius; W. D. Hopkins, Trinity Hall; N. W. Jenkin, Christ's; A. R. Jordan, Clare; J. L. Joyce, King's; R. P. Lamb, Trinity; A. A. H. Lawrence, B.A., and W. S. Leicester, Emmanuel; R. G. Markham, Caius; W. Mathieson, Sidney Sussex; L. Meakin and M. W. B. Oliver, Trinity; E. S. Perrin and A. H. Platt, Caius; A. V. Poyser, Magdalene; C. H. Rippmann, B.A., King's; J. H. Roberts, Emmanuel; S. H. Scott, St. John's; R. E. Smith, Emmanuel; C. Stanley-Clarke, B.A., Caius; F. A. Stockdale, Magdalene; O. Teichmann, F. B. Treves, B.A., and W. W. Treves, Caius; G. Walker, Trinity; K. M. Walker, Caius; D. R. P. Walther, Pembroke; C. E. Whitehead, Caius; and T. M. O. Williams, Christ's.

*Part II. Elementary Biology*.—F. O. Arnold, Trinity; E. W. Atkinson, Caius; J. Barcroft, M.A., King's; H. S. Berry, Clare; J. P. Buckley and L. S. T. Burrell, Trinity; H. V. Byatt-Byatt, Clare; H. J. B. Cane, Caius; P. Clayton and R. Colgate, Trinity; R. Crawford, Jesus; G. H. Davy, Caius; H. Dimock, Sidney Sussex; N. H. Gandhi and J. F. Gaskell, B.A., Caius; G. Graham, Trinity; B. Haigh, Caius; H. A. Hancock, Non-Collegiate; H. W. Hesse, Trinity Hall; F. H. Holl, Trinity; W. D. Hopkins, Trinity Hall; E. C. D. Marriage, Clare; J. H. B. Martin, Emmanuel; B. N. Nutman, Jesus; W. S. Perrin and A. H. Platt, Caius; C. H. Rippmann, B.A., King's; S. H. Scott, St. John's; R. C. Standing-Smith, B.A., Catharine; H. H. Taylor, Pembroke; K. M. Walker, Caius; H. K. Waller, Trinity; and C. E. Whitehead and W. H. Williams, Caius.

### SECOND EXAMINATION.

*Part I. Pharmaceutical Chemistry*.—W. A. Alexander, Caius; J. H. Board, Pembroke; L. B. Cane, King's; A. de C. C. Charles, Magdalene; H. J. Clarke, Trinity; E. B. Clayton, Caius; A. W. C. Drake, Pembroke; J. R. Draper, St. John's; D. Embleton, Christ's; M. F. Emrys-Jones, Caius; S. Gooding, B.A., St. John's; G. S. Haynes, King's; G. A. M. Heydon and G. Holroyd, B.A., Christ's; R. S. Jenkins, St. John's; C. E. M. Jones, King's; S. G. Luker, Pembroke; R. M. Miller, B.A., Clare; H. E. H. Oakley, B.A., St. John's; E. V. Oulton, Christ's; D. G. Pearson, Pembroke; M. Phillips, B.A., Caius; J. H. Pratt, Trinity; F. Shingleton Smith, B.A., King's; S. J. Steward, Downing; R. Svensson, Caius; R. Wade, B.A., Christ's; B. Wahby, Non-Collegiate; G. L. Webb, Caius; H. N. Webber, St. John's; A. Wilkin, B.A., King's; and W. H. Woodburn, B.A., and O. K. Wright, Christ's.

*Part II. Human Anatomy and Physiology*.—C. B. M. Aldridge, B.A., Christ's; E. Beaton, Caius; H. C. Cameron, B.A., St. John's; M. A. Cassidy, B.A., and H. M. Clarke, B.A., Clare; E. R. T. Clarkson, M.A., H. Selwyn; R. P. Cockin, B.A., Caius; W. I. Cumberlidge, Christ's; C. E. Droop, B.A., Trinity; T. Drysdale, B.A., Jesus; L. Dukes, B.A., Trinity; T. W. N. Dunn, Caius; R. G. Elwell, B.A., Trinity; H. J. Fardon, B.A., Christ's; N. C. Fletcher, B.A., Queen's; D. H. Fraser, B.A., Caius; S. H. Gibson, B.A., and H. E. Graham, B.A., Jesus; R. E. G. Gray, B.A., Pembroke; J. R. C. Greenlees, B.A., St. John's; C. F. R. Hall, B.A., Trinity; H. Hardwicke-Smith, B.A., St. John's; W. H. Hastings, Trinity; W. Hastings, Christ's; R. F. V. Hodge, Emmanuel; W. R. Honeyburne, Peterhouse; E. C. Hughes, B.A., and N. H. Illingworth, B.A., Clare; F. A. Juler, B.A., and C. King, B.A., Trinity; J. C. Lawton-Roberts, B.A., Clare; W. Lowe, B.A., Caius; G. H. K. Macalister, B.A., St. John's; J. McIntyre, King's; S. M. Mackenzie, B.A., Trinity; J. T. Macnab, B.A., Christ's; C. D. Mathias, B.A., Trinity; J. Mellanby, B.A., Emmanuel; A. H. Miller, B.A., Trinity; A. R. Moore, B.A., Caius; S. A. Owen, B.A., Trinity; C. E. Palmer, B.A., Caius; C. W. Ponder, B.A., Emmanuel; W. H. Robinson and E. W. S. St. B. B.A., Downing; G. C. E. Simpson, St. John's; W. H. Smyth, B.A., Emmanuel; W. H. Thresher, B.A., Caius; G. T. Western, B.A., Pembroke; W. P. Williams, Downing; E. K. Williams, B.A., Caius; and J. K. Willis, B.A., Queen's.

### THIRD EXAMINATION.

*Part I. Surgery and Midwifery*.—J. F. Alexander, B.A., Trinity; J. A. Andrews, B.A., St. John's; L. B. Axling, B.A., Christ's; L. E. H. R. Barker, B.A., Caius; G. D. Barton, B.A., Pembroke; J. M. Bennion, B.A., St. John's; E. Bigg, B.A., Caius; F. Bryan, B.A., King's; C. V. Bulstrode, B.A., Trinity; J. W. E. Cole, B.A., Corpus Christi; G. L. Crimp, B.A., Caius; H. Davies-Colley, B.A., Trinity; S. Dodd, B.A., Caius; F. P. Edwards, Downing; A. F. Elliott, B.A., Emmanuel; R. B. Etherington-Smith, B.A., Trinity; A. O. M. Fehrsen, B.A., Caius; W. S. Fox, M.A., Trinity; G. W. Greene, B.A., Downing; G. P. D. Hawker, B.A., Caius; F. B. Manser, Peterhouse; J. C. Matthews, B.A., Downing; C. L. Nedwill, B.A., Trinity; F. D. Nicholson, B.A., King's; G. B. Norman, B.A., St. John's; F. H. Parker, B.A., Pembroke; J. E. Payne, Peterhouse; J. S. Pearson, B.A., Trinity; H. V. Pryce, B.A., St. John's; R. M. Ranking, B.A., Pembroke; F. Richmond, B.A., Clare; C. Roper, B.A., Caius; E. A. Ross, Trinity; H. M. Scaping, B.A., Clare; E. S. Scott, B.A., Pembroke; W. T. Scott, B.A., Clare; H. J. Shoue, B.A., Emmanuel; A. I. Simey, B.A., and G. E. St. C. Stockwell, B.A., King's; E. Weatherhead, St. John's; H. C. Williams, B.A., Pembroke; and J. A. Wool, M.A., St. John's.

THE Prince of Wales has now, we understand, definitely consented to become President of the National Association for the Prevention of Consumption and Other Forms of Tuberculosis.

ROYAL UNITED HOSPITAL, BATH.—The eighth annual amateur dramatic performances were given last week at the Theatre Royal, Bath, in aid of the funds of the Royal United Hospital. The pieces selected were *The Yeoman of the Guard* and *The Two Roses*. The performances were an undoubted success and it is thought that the hospital will benefit substantially.

INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of the North-Western Branch of the Incorporated Society of Medical Officers of Health was held at the Victoria Hotel, Manchester, on Dec. 13th, when Dr. E. W. Hope described the administrative measures adopted in Liverpool upon an outbreak of plague. With regard to contacts the practice was to keep them in their own homes and for each one to be visited and interrogated daily for a fortnight. They were not taken to isolation homes belonging to the corporation. The annual dinner of the branch was subsequently held and was presided over by Mr. T. W. H. Garstang. The principal guest was Professor Sheridan.

Delépine who was presented during the evening by Mr. Francis Vacher, on behalf of members of the society and others, with a silver rose bowl. The presentation was intended to commemorate the election of Professor Delépine as an honorary fellow of the society.

**UNIVERSITY OF WALES.**—The Prince of Wales has been unanimously nominated as Chancellor of the University of Wales.

**BIRMINGHAM HOSPITAL SUNDAY FUND.**—The amount of £5547 has been received from the Hospital Sunday offerings this year, a sum which has not been equalled since the year 1876. The authorities of the General Hospital are the recipients on the present occasion.

**PRESENTATION TO A MEDICAL PRACTITIONER.**—Mr. M. A. Adams, F.R.C.S. Eng., was on Nov. 29th presented with his portrait in oils in recognition of his long gratuitous and beneficial services as surgeon to the Kent County Ophthalmic Hospital. The portrait will be suspended on the hospital walls.

**ROYAL BRITISH NURSES' SETTLEMENT FUND.**—A sale in aid of this fund will be held on Feb. 6th and 7th, 1902, at 24, Park-lane, London, W., the residence of Lord Brassey. Princess Christian will open the sale and will preside at one of the stalls. The object of the fund is to secure a comfortable old age for nurses.

**DRAINAGE OF DORCHESTER.**—At the meeting of the Dorchester Town Council held on Dec. 10th it was reported that the Local Government Board had approved of the method of sewage disposal in connexion with the new scheme being altered to the septic system; an additional loan of £3000 for sewerage works in the extended part of the town was also sanctioned.

**TAVISTOCK COTTAGE HOSPITAL.**—In the Chancery Division on Dec. 10th an order was made with reference to the £10,000 recently left by the late Mr. Gill to the Tavistock Cottage Hospital. It was decided that the authorities of the hospital should erect a wing to be called the Gill Wing at a cost of about £1500 and that the income of £10,000 should be applied to its maintenance, and an order was made accordingly.

**BEQUESTS TO WEST OF ENGLAND CHARITIES.**—The late Mr. E. Halsall of Bristol, who died in September last and who was for more than 50 years a member of the executive committee of the Bristol General Hospital, has bequeathed £200 each to the Bristol General Hospital and the Bristol Royal Infirmary.—The late Mr. H. D. Skrine of Claverton Manor, Somerset, has bequeathed £100 each to the Royal United Hospital, Bath, Bath Mineral Water Hospital, and the Bath Eye Infirmary.

**MEASLES AT EXMOUTH.**—At the meeting of the Exmouth District Council held on Dec. 4th, the medical officer of health reported that an outbreak of measles commenced in the middle of June and lasted until September. The total number of notifications received was 235 and 15 cases ended fatally, the rate of mortality being 6.38 per cent. He added that the number of notifications did not correctly represent the actual number of cases, for a large number of children had not been attended by a medical man and consequently were not reported.

**BRIDGWATER INFIRMARY.**—The eighty-eighth annual report of the Bridgwater Infirmary has just been issued. It states that during the 12 months ended August 31st last 339 in-patients had been admitted, compared with 348 in the previous year. The out-patients numbered 2141, against 2149 in 1900. The financial statement shows that the total income amounted to £3201, and the expenditure was £2314. The Hospital Sunday Fund amounted to £228. The reserve fund of the institution now amounts to £6800.

**SUICIDAL MANIA.**—At the Bristol Lunatic Asylum on Dec. 11th an inquiry was held concerning the death of a female patient, aged 50 years, who escaped on Dec. 9th and whose body was subsequently found in the river which runs close to the institution. A nurse whilst bathing the patients had left the keys of the ward doors on the bath-room mantelpiece, and the deceased contriving to get them was able to let herself out. A verdict of "Suicide whilst of unsound mind" was returned, and the coroner reproved the nurse for allowing the keys to go out of her possession.

## Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ADDINSELL, J. H., M.R.C.S., L.R.C.P., has been appointed House Accoucheur to King's College Hospital.  
BALDWIN, G. P., L.R.C.S. Edin., has been appointed Public Vaccinator for the Shannon District of New Zealand.  
BOAG, JAMES, M.B., M.S. Glasg., has been appointed Certifying Surgeon under the Factory Acts for the Wishaw District of Lanarkshire.  
BREHAUT, A. H., M.R.C.S., L.R.C.P., has been appointed House Surgeon to King's College Hospital.  
BULTEEL, C. E., M.R.C.S., L.R.C.P., has been appointed House Physician to King's College Hospital.  
CARLE, F. C., M.R.C.S., L.R.C.P., has been appointed House Physician to King's College Hospital.  
CHEATLE, GEORGE LENTHAL, C.B., F.R.C.S., has been appointed Surgeon to the Italian Hospital, Queen-square.  
COATES, C. M., L.R.C.P. Edin., L.R.C.S. Edin., has been appointed Certifying Surgeon under the Factory Acts for the Creech St. Michael District of Somerset.  
CUDMORE, ARTHUR MURRAY, M.B. and Ch.B. Adel., M.R.C.S. Eng., has been appointed Honorary Assistant Surgeon to the Adelaide Hospital, Australia.  
DEANE, ANDREW, M.D., F.R.C.S.I., Lieutenant-Colonel, I.M.S. (retired), has been appointed Superintendent to the Royal Victoria Hospital, Belfast.  
HAMILTON, T. K., M.D., F.R.C.S.I., has been re-appointed Director of the Local Board of South Australia of the Australian Mutual Provident Society.  
HIND, WHEELTON, M.D. Lond., F.R.C.S. Eng., has been appointed Senior Honorary Surgeon to the North Staffordshire Infirmary and Eye Hospital.  
HOWSE, N. R., M.R.C.S. Eng., V.C., has been appointed Visiting Surgeon to the Gaol, New South Wales.  
JOHNSTON, S. E., M.B., C.M. Edin., has been appointed Assistant Resident Medical Officer to St. Mary's Hospital for Sick Children, vice T. E. Frazer-Toovey.  
KELYNACK, T. N., M.D., M.R.C.P., has been appointed Assistant Physician to the Mount Vernon Hospital for Consumption, Hampstead, Northwood, and Fitzroy-square.  
MAXWELL, W. W., M.B., Ch.B. Edin., M.R.C.S., L.R.C.P., has been appointed House Physician to King's College Hospital.  
MCLEOD, J. A., M.R.C.S., L.R.C.P., has been appointed House Accoucheur to King's College Hospital.  
PARKE, T. H., M.R.C.S., L.R.C.P. Edin., has been appointed Certifying Surgeon under the Factory Acts for the Tideswell District of Derbyshire.  
PEREIRA, JOSEPH ANTHONY WENCESLAUS, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Exeter Workhouse.  
POOLER, EDWARD LESLIE, M.D. R.U.I., L.K.Q.C.P.I., has been appointed Medical Officer to the Destitute Poor and Aborigines of the District of Stirling, South Australia.  
ROGERS, F. C., F.R.C.S.E., L.R.C.P.E., has been appointed Medical Officer of Health to the Erith District Council, vice Mr. John Elliot, resigned.  
STANTON, W. D., F.R.C.S. Edin., has been appointed Honorary Consulting Surgeon to the North Staffordshire Infirmary and Kyo Hospital.  
STUART, W. L., M.B., B.S. Lond., M.R.C.S., L.R.C.P., has been appointed House Surgeon to King's College Hospital.  
WILLCOX, H. L., M.R.C.S., L.R.C.P., has been appointed House Surgeon to King's College Hospital.  
WORGER, R. G., M.R.C.S., L.R.C.P. Lond., L.S.A., has been appointed Surgeon under the Factory Acts for the Radstock District in the County of Somerset.

## Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index).*

**BIRMINGHAM AND MIDLAND FREE HOSPITAL FOR SICK CHILDREN.**—Resident Surgical Officer. Salary £60, with board, washing, and attendance.  
**BIRMINGHAM GENERAL DISPENSARY.**—Resident Surgeon, unmarried. Salary £150 per annum, with rooms, fire, lights, and attendance.  
**BRADFORD ROYAL INFIRMARY.**—Dispensary Surgeon, single. Salary £100 per annum, with board and residence.  
**CHELSEA, BROMPTON, AND BELGRAVE DISPENSARY, 41, Sloane-square, Chelsea, S.W.**—Honorary Surgeon.  
**CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.**—Clinical Assistant.  
**CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, N.**—Second House Physician for six months, with board, washing, and residence. Salary at the rate of £30 per annum.  
**DEVONSHIRE HOSPITAL, Buxton, Derbyshire.**—House Surgeon and Assistant House Surgeon. Salary, House Surgeon £100 per annum, Assistant £50 per annum, with apartments, board, and lodging.  
**EYE AND EAR INFIRMARY, Liverpool.**—House Surgeon. Salary £80, with residence and maintenance.  
**GLASGOW ROYAL INFIRMARY.**—Superintendent. Salary £500 per annum, with board, residence, &c.  
**GREAT NORTHERN CENTRAL HOSPITAL.**—Assistant House Surgeon for six months. Salary at the rate of £30 per annum, and board.

**HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.**—Resident House Physicians for six months. Honorarium of £25.  
**JAFFRAY BRANCH OF THE GENERAL HOSPITAL, Gravelly-hill, near Birmingham.**—Resident Medical and Surgical Officer. Salary £150 per annum, with board, residence, and washing.  
**KIDDERMINSTER INFIRMARY AND CHILDREN'S HOSPITAL.**—House Surgeon. Salary £140 (increasing to £170), with rooms and attendance.  
**LANARK COUNTY ASYLUM, Hartwood, Glasgow.**—Third Assistant Medical Officer and Pathologist. Salary £120 per annum, with fees, board, washing, and residence.  
**LIGHTBURN JOINT HOSPITAL FOR INFECTIOUS DISEASES, Shettleston, near Glasgow.**—Resident Physician. Salary £130 per annum, with board, &c.  
**MOUNT VERNON HOSPITAL FOR CONSUMPTION, Hampstead, and North-wood, Middlesex.**—Honorary Anaesthetist.  
**NORFOLK COUNTY ASYLUM, Thorpe, Norwich.**—Junior Assistant Medical Officer, single. Salary £120 per annum, with board, lodging, and washing.  
**NOTTINGHAM GENERAL HOSPITAL.**—Assistant House Surgeon. Salary £100, with board, lodging, and washing.  
**QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.**—Assistant Resident Medical Officer for four months. Salary at rate of £50 per annum, with board, residence, and washing.  
**ROYAL DEVON AND EXETER HOSPITAL, Exeter.**—Senior Assistant House Surgeon for six months. Salary at rate of £30 per annum, with board, lodging, and washing.  
**ROYAL HOSPITAL FOR INCURABLES, Donnybrook, Dublin.**—Resident Medical Officer, unmarried. Salary £150, with board and apartments.  
**ROYAL PORTSMOUTH, PORTSEA, AND GOSPORT HOSPITAL.**—Assistant House Surgeon required for six months. Remuneration at rate of £50 per annum, with board and residence.  
**ST. BARTHOLOMEW'S HOSPITAL.**—Surgeon.  
**ST. THOMAS'S HOSPITAL.**—Resident Assistant Physician.  
**SOUTH DEVON AND EAST CORNWALL HOSPITAL, Plymouth.**—House Surgeon. Salary £100, with board and residence.  
**STATE CRIMINAL LUNATIC ASYLUM, Broadmoor, Crowthorne, Berks.**—Junior Assistant Medical Officer, single. Salary £175, rising to £200 per annum, with furnished quarters, coal, gas, and attendance.  
**STROUD GENERAL HOSPITAL.**—House Surgeon. Salary £80 per annum, with board, lodging, and washing.  
**SUNDERLAND INFIRMARY.**—House Surgeon. Salary £100, increasing, with board and residence.  
**WESTMINSTER GENERAL DISPENSARY.**—Honorary Surgeon.  
**WESTMINSTER HOSPITAL, opposite Westminster Abbey.**—Aural Surgeon.  
**WESTMORLAND CONSUMPTION SANATORIUM.**—Resident Medical Officer, single. Salary £150, all found.  
**WHITECHAPEL UNION INFIRMARY, Vallance-road, N.E.**—First Assistant Resident Medical Officer. Salary £130 per annum, rising to £150, with rations, apartments, coal, gas, and washing.

## Births, Marriages, and Deaths.

### BIRTHS.

**ROE.**—On Dec. 11th, at 121, Old-street, E.C., the wife of William Francis Roe, L.R.C.P.I., L.R.C.S.I., and L.M., of a daughter.  
**SUTHERLAND.**—At 32, George-square, Edinburgh, on the 17th inst., the wife of L. R. Sutherland, M.B., Professor of Pathology, University of St. Andrews, a daughter.  
**THOMSON.**—On Dec. 15th, at Kirkston, Spa-road, Radipole, Weymouth, the wife of David Thomson, L.R.C.P. Edin., L.R.C.S. Edin., L.F.P.S. Glasg., of a son.

### MARRIAGES.

**ATKEY—MENZIES.**—On the 14th inst., at Holy Trinity, Ryde, by the Rev. W. M. Cameron, vicar, Percy J. Atkey, M.R.C.S., L.R.C.P., D.P.H. Camb., of Southampton, eldest son of C. J. Atkey, Esq., Exmouth (late Streatham), to Barbara, only daughter of the late Captain William Menzies, R.N., and Mrs. Menzies, Ryde.  
**BATTY—ROY.**—On the 17th inst., at S. Peter's, Southborough, James Henly Batty of the Gold Coast and London, to Violet, widow of the late Professor Roy, F.R.S., and daughter of the late Sir George B. Paget, K.C.B., F.R.S., of Cambridge.  
**BOWEN-JONES—EVANS.**—On Dec. 12th, at Saint Catherine's Church, Neath, South Wales, Lloyd Bowen-Jones, M.R.C.S., L.R.C.P. Lond., D.P.H., to Clara, daughter of the late Edward Evans, Esq.  
**FOSTER—DALLAS.**—On Dec. 12th, at Christ Church, Brockham, by the Rev. P. G. Ward, M.A., vicar of Braughing, Herts, M. Bernard Foster, M.R.C.S. Eng., L.R.C.P., D.P.H. Lond., of Puckeridge, Herts, younger son of Michael E. Foster, of Brockham, Surrey, to Gertrude Mary, elder daughter of Seymour Dallas, J.P., of Kimberley, S. Africa.  
**STAHLKNECHT—GARDNER.**—On Dec. 12th, at the parish church, West Kirby, Cheshire, Bernard Stahlknecht, M.B., Ch.B. Vict., to Ethel Cleland, only daughter of R. B. Gardner, of West Kirby.  
**TAUNTON—SMITH.**—On Dec. 12th, at St. Peter's Church, Bengeworth, John Godfrey Cresswell Taunton, M.R.C.S., L.R.C.P. Lond., to Edna Harriet, eldest daughter of Mr. and Mrs. Edwin Smith.

### DEATHS.

**SPENCE.**—At Burntisland, on the 11th inst., Annabella Bain, wife of Robert Spence, M.B., C.M.  
**WILLIAMS.**—On Dec. 14th, at Cheap-street, Sherborne, Dorset, Mary, widow of the late W. H. Williams, M.D., aged 79.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

## Notes, Short Comments, and Answers to Correspondents.

### MEDICAL AID SOCIETIES AND THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS.—We will not combine ourselves—why? Because there are many in the profession who would not be happy if they had not the idea in their heads that they were taking someone else's patients or holding some miserable club which someone else wanted. May the Medical Defence Union grow so strong that it may be able to swamp out all medical men who degrade a noble profession by pandering to the public for their own (as they think) gain.

I am, Sirs, yours faithfully,

Dec. 16th, 1901.

GENERAL PRACTITIONER.

To the Editors of THE LANCET.

SIRS.—Certainly, we English are droll. A short time since our hospital out-patient department was the bogey, now it is medical aid societies, and for the time being nothing can be said too bad about them. We have a society formed to put them down; the said society lays its grievances before the General Medical Council; which in turn notifies by circular that "the Council strongly disapproves of medical practitioners associating themselves with medical aid associations." Next the Council convicts an unlucky wight for committing the offence and postpones action for six months. Why? Because the Council knows full well that it can do nothing. Can they remove a man from the Register for "infamous conduct in a professional respect" in taking low fees? If so, the millennium is surely close at hand. Would not an action lie against the Council if it did so? and would not an appeal to the Privy Council soon declare that removal for such a cause was *ultra vires*? The fact is that the General Medical Council knows no more about the doings of general practitioners than—nor indeed so much as—a "jury of matrons." It is composed of nominees of the Colleges and has no interest in general practitioners who form at least three-fourths of the men on the Register, and therefore it is fortunate that it really has no power over them. The Council was appointed to regulate the examinations for qualifications and to register those who were qualified; and if it be necessary, as I hold it is, that the relations of medical practitioners with each other and the public should be regulated this must be done by a house of representatives. To have the General Medical Council constituting itself a trade union when "the trade" is not represented is absurd on the face of it. I am aware that medical aid associations have injured and tyrannised over medical men in some districts, but this is by no means general. In my own locality they have been useful. No attempt has been made to enrol other than working-class members. One cannot, and one would not, wish to refuse attendance on the poor, but they cannot pay long bills and they do not pay one-fifth of what is sent in to them, and what they do pay is reduced by collector's commission—which simply represents the percentage retained by the medical aid societies—and I always look upon it that every £50 received from a medical aid society as so much to the good and that it relieves me of at least £250 of bad debts. Any business-like set of practitioners could frame regulations which would stop the canvassing of other men's patients and the admission of those whose income places them above the assistance of such associations, or the placing of paid servants of a society in a town to compete with the resident practitioners. But if the Council is asked to excommunicate all those who take low fees what shall we ask them to do with those experts and specialists who in hospitals provided by the benevolence of the charitable attend *gratuitously* both in- and out-patients, 75 per cent. of whom are well able to pay for medical attendance?

I am, Sirs, yours faithfully,

Dec. 18th, 1901.

ANTI-HUMBUG.

### LOOKING BACK.

To the Editors of THE LANCET.

SIRS.—In your interesting, amusing, and, I may add instructive, quotation from THE LANCET of Nov. 30th, 1823 (I say instructive because it affords a comparison between the tendency of thought of the present school and that of a period more closely allied to mediæval times), I may be pardoned if I remark that I do not think the views of Dr. Pearson run current with the present age without a grain of salt. The nearest resemblance, as I conceive, to this remarkable Biblical narrative as a natural process consists in pike-fishing, a pastime which as a youth I was an ardent lover of, and it so happened that what is known as "live-bait fishing" was my favourite branch of the art. As every fisherman knows, when the pike are not ferocious, or, to use the sporting term, "not on the feed," the float may disappear and reappear after a short interval, the live bait having been disgorged, but still living, thus enabling one to throw out the same bait without rebaiting. This is a very different situation from Jonah's, who was disgorged after an incarceration of three days; but it occurs to me as the nearest resemblance. Now, according to Dr. Pearson's hypothesis,

the narrative of Jonah reported no miracle at all, but solely natural phenomena; indeed, according to his account, to put it plainly, Jonah seems to have suffered, after three days' immersion, little or no inconvenience. However, taking a more scientific view of this case, Dr Pearson appears to have established the fact—if a fact—early "that the stomach had no power over substances imbued with vitality."

With regard to what Dr. Pearson terms the "minor point"—that is to say, how Jonah procured his sustenance—this can easily be disposed of apart from the miraculous, because the fasting experiments of modern times clearly eclipse Jonah's record for prolonged starvation; but with regard to the "respiratory process" this appears to me to be more difficult and enigmatical to account for according to natural phenomena. A case was reported in the daily papers some time ago of a whale (and let us assume the fish to have been a whale) at an aquarium which was unfortunately drowned through the intrusion of an insect rendering the valve of the ear inoperative, and it occurred to me when I read thereof how long, roughly speaking, a whale could remain under water without rising in order to recharge its breathing apparatus. I believe about four minutes is specified as the limit for man to sustain complete submersion, still retaining life—that is to say, amenable to resuscitation. How long could the whale thus remain? It might be possible for the whale to compensate Jonah in supplying air for changed atmospheric conditions, these points being beyond me, although I venture to guess that Jonah had a miraculous escape from death by drowning or suffocation.

With regard to Dr. Pearson as a logician he appears to me to have outwitted himself, because, supposing he could have explained all the remarkable narratives in Scripture by natural causes, he clearly undermines Scripture, because the Gospels insist upon the miraculous. What he would gain in one direction he would lose in another. The only question remains whether his advocacy was a hindrance rather than an aid to Christianity.

Peckham, S.E., Dec. 14th, 1901.

CLEMENT H. SERP.

#### FEES FOR INSURANCE EXAMINATIONS.

To the Editors of THE LANCET.

SIRS,—Kindly favour me with space for a few lines in reply to the letter that appeared in your last issue. It contains at least three grave misstatements: (1) The examination required is not "unusually rigorous"; (2) the report does not consist of "three sides of foolscap"; (3) the medical questions are *ten* in number, not "60," at stated by your correspondent. The fee for examinations has been fixed by our medical advisers at 10s. 6d., and for the report in question this has hitherto been regarded as a reasonable fee. Apart from this company, the societies providing sickness benefit are chiefly friendly societies, and I understand that candidates for admission to these societies are frequently examined for considerably less than even 10s. 6d., and I do not remember to have heard any demand for a guinea fee, which, of course, would be impossible.—I am, Sirs, yours faithfully,

HENRY BROWN, Manager.

The Century Insurance Company, Limited, Edinburgh,  
Dec. 16th, 1901.

#### FRIENDLY SOCIETIES AND THEIR MEDICAL AID INSTITUTIONS.

To the Editors of THE LANCET.

SIRS,—My letter on the above subject was simply to demonstrate the illegal position of these institutions and the grave abuses which are inherent to their constitution. Your correspondent, "C. W.," complains of my language and reads into my letter the word "insolent" which I did not use. If I wished to introduce a personal element into this discussion I could not do so, for "C. W." is to me only two alphabetical signs, and I have no such desire. I attack a system, not a person; and having fought that system now for 20 years I shall not try to conciliate it by smooth words. If the committee of a hospital were to employ their house surgeon to attend them as charity patients we should have a case approaching that supplied by medical aid societies. The pence of the poor pay for the cheap doctoring of the middle class—the publican, the tradesman, the schoolmaster. The whole thing on the part of these people, who need no concession from the profession, is a piece of Pecksniffian philanthropy. "C. W." compares medical aid associations with insurance companies. The latter canvass; they do not. I admit there is no direct canvass; it is not needed. The friendly societies are so fully organised that by simply including wives and children they have at once a large enough number of members to secure the services of a medical attendant. They start the practice when they first advertise, they carry it on by the aid of their professional—or unprofessional—nominee, who is solely and simply their servant and is usually paid at the rate of 2d. to 3d. a consultation, including visits. His name upon the door-plate covers this cooperative society, which is behind him, engages him or dismisses him. "C. W." quotes Sir W. Foster and Dr. Glover. With Sir W. Foster I had some years ago a correspondence on this subject, and I found his attitude weak. He deplored the lack of union in our ranks which made the matter almost hopeless. Dr. Glover's attitude I do not know, but Sir Dyce Duckworth spoke out strongly enough and ultimately he will voice our will, for he told us that the General Medical Council did not raise the standard of medical education in order that this sort of thing should be supported. There is only one practicable solution of this problem. Recognising the needs of the poor we treat a certain section of the public on nominal terms. We, then, not the philanthropic layman who wishes to unite with the poor in this matter, must be the judges

of who shall have medical attendance in this way. There is the crux. The clubs say, "We shall dictate the terms and scope of your club-work." The answer is easy enough, "You shall not, we will make our own arrangements." That has been, and I hope will always be, my attitude. I have not seen the liberal support of hospitals which "C. W." notes. I believe in Birmingham and some other towns large sums are contributed in this way, and I fear the provident element is invading to some extent our medical charities. The outcome of this feeling is shown in the late cooperative attempt in that city. If "C. W." would care to see them, I should be glad to send him privately instances of the weak points and abuses of the institutions he champions.

I am, Sirs, yours faithfully,

Loughborough, Dec. 16th, 1901.

J. B. PIKE.

#### THE FREQUENCY OF TRICHINOSIS IN THE UNITED STATES.

GERMANY has always been regarded as the only country in which trichinosis is especially rife, and this is of course due to the habit of a large number of its people of eating pork in an uncooked state. The United States is the land of the hog, but despite this fact the belief has been current that trichinosis is a disease comparatively rare among its inhabitants. A systematic examination of pork made for commercial reasons in the United States has shown the frequency of trichinosis in hogs to be about 2 per cent. Dr. Herbert A. Williams, professor of pathology, medical department, University of Buffalo, was struck by the apparent lack of any such systematic researches upon the frequency of trichinosis in human subjects, either in America or in Europe, and for the space of several years he has been closely investigating the matter, the results of which investigations he has published in the *Boston Journal of Medical Research*. Dr. Williams began his studies in 1894, and from that date up to this year 505 cadavers have been examined, trichinae being found present in 27 or 5.34 per cent. Of these the United States white population contributed 2.89 per cent.; United States coloured, 7.14; British and Irish, 8.06; Canadian, 16.6; German, 12.24; and Italian, 16.66 per cent. Dr. Williams summarises the result of his investigations as follows: 1. Samples of muscles secured at 505 unselected necropsies on adult human subjects were examined microscopically for trichinae. In 27 cases, or 5.34 per cent., trichinae were present. 2. All of the subjects died from other diseases than trichinosis. The infection with trichinae must in every case have occurred a considerable time previously. 3. The infections were of various degrees of severity, being sometimes very extensive and sometimes so slight that only one or two worms were detected. 4. The birthplaces of the subjects included the most important countries of North America and Europe. The number of cases was not large enough to allow accurate conclusions to be formed as to the influence of nationality upon the frequency of the disease. The fact that a large proportion of cases occurred in persons who were born and had lived in the United States is important. 5. An unusually high percentage of cases occurred among persons who had been insane. 6. Examinations of sections from the above cases for eosinophilic cells failed to show such cells about or near the encapsulated trichinae. 7. Mast cells do not collect in or about the capsules in cases of old trichinosis. 8. Plasma cells occasionally appear in or about the capsules. 9. Newly-formed elastic fibres sometimes appear about the capsules. 10. As described by Leuckart and Langerhans the capsules may be invaded by new cells, the worms disintegrate, and thus the capsules become filled with fibrous and adipose tissue. The investigations of Dr. Williams have brought out some extremely interesting and instructive points, the chief of which are these, that trichinosis is much more prevalent than is commonly believed in the United States, and especially is this true as regards the white population. Dr. Williams gives a probable and plausible explanation of this occurrence as being due to the custom of many American farmers of eating uncooked or partially cooked pork. The other point to which attention may be drawn is the prevalence of trichinosis among the insane, which may perhaps be attributed to the careless mode of feeding practised by persons thus afflicted before they are placed under restraint. The outcome of Dr. Williams's researches emphasises the need of careful microscopic examination of pork before it is exported, and the necessity of the meat being thoroughly cooked before it is used as food if the troublesome parasite is to be effectually kept out of the human body.

*Obstetrician* is certainly entitled to a fee if he was unconditionally engaged to attend the case. But if he was engaged only in the event of the absence of the first medical man, and the contingency did not arise (the first medical man being available), we do not think that he can claim a fee. Probably no definite arrangement was come to, the patient's husband believing the condition to be understood and our correspondent believing that there was no condition whatever attached to his engagement. If this is the case, would it not be better that a common friend should be invited to arbitrate? There can be no hard-and-fast professional rule that will provide for the results of a misunderstanding.

*Rostrum*.—A thing may be true and yet not worth saying. We advise our correspondent not to take the course that he proposes. If he think that a private remonstrance would be misunderstood it would be better to get someone else to put the right view before the offender.

*Oakdene*.—The greater part of our correspondent's speculations are

only possible to one devoid of anatomical and physiological knowledge. In one or two points he has guessed right, and these points he will find in every text-book of medicine.

**Fairplay.**—Only a combination among medical men can successfully deal with a medical aid society. Fairplay, we presume, knows the strength of his position and whether it will justify him and his colleague in sticking to their guns.

**Bat.**—In the circumstances narrated by our correspondent we think that 10 or 15 guineas would be a reasonable charge for each operation, taking into consideration the pecuniary position of the father.

**A late Public Vaccinator.**—We are in sympathy with much of our correspondent's letter, but we doubt if it would serve any practical purpose to reprint it.

**Furnace.**—The address is Gravel-lane, Southwark-street, S.E. Our correspondent should consult THE LANCET, Nov. 30th, 1901.

**Anonymous.**—We have forwarded the postal orders to the William Smyth Fund.

**A. G.** has acted in the proper spirit.

**During the week marked copies of the following newspapers have been received:**—*Macclesfield Times, Macclesfield Courier and Herald, Yorkshire Post, Reading Mercury, Mining Journal, Local Government Chronicle, Hertfordshire Mercury, Dorset County Chronicle, City Press, Norfolk Standard, Halifax Evening Courier, Alliance News, Lincoln Echo, Sydney Daily Telegraph, South Wales Press, Perth Journal, Liverpool Courier, Surrey Advertiser, Local Government Journal, Courrier de la Presse (Paris), Le Journal des Débats, Le Progrès Médical, Le Voltaire, La Politique Coloniale (Paris), Herts Observer, Stafford Advertiser, Durham Advertiser, Preston Herald, Hereford Times, Hull News, Liverpool Daily Post, Southern Echo, Dunfermline Journal, Plymouth News, East Anglian Times, Sussex News, Leeds Mercury, Worcester Chronicle, Walsall Observer, Swansea Herald, Dundalk Examiner, Birmingham News, Blyth News, Auto-motor Journal, Eastbourne Chronicle, &c.*

## Medical Diary for the ensuing Week.

### OPERATIONS.

#### METROPOLITAN HOSPITALS.

**MONDAY (23rd).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynaecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopaedic (2 P.M.), City Orthopaedic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M.).

**TUESDAY (24th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Bar (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

**WEDNESDAY (25th).**—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopaedic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.).

**THURSDAY (26th).**—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynaecological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

**FRIDAY (27th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's

(2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square, (9.30 A.M.), City Orthopaedic (2.30 P.M.).

**SATURDAY (28th).**—Royal Free (9 A.M. and 2 P.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.), Throat, Golden-square (9.30 A.M.). At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

## EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	... £1 12 6	One Year	... £1 14 8
Six Months	... 0 16 3	Six Months	... 0 17 4
Three Months	... 0 8 2	Three Months	... 0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed. THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

# A Lecture ON HEMIPLEGIA.

*Delivered at the National Hospital for the Paralyzed and Epileptic, Queen-square, on Nov. 29th, 1901,*

By JAMES TAYLOR, M.A., M.D. EDIN.,  
F.R.C.P. LOND.,

PHYSICIAN FOR OUT-PATIENTS TO THE HOSPITAL; PHYSICIAN TO THE NORTH-EASTERN HOSPITAL FOR CHILDREN, AND TO THE ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.

GENTLEMEN,—The subject of my lecture this afternoon is hemiplegia, by which is meant that condition in which power is impaired on the whole of one side of the body. In the common variety of this form of paralysis one arm, one leg, one half of the face and of the tongue, and one half of the trunk are affected on the same side. In another variety one arm, one leg, and one side of the trunk are affected on one side, while the face is affected on the other. The latter is known as "crossed" or "alternate" hemiplegia. There is another form of crossed hemiplegia in which the arm, the leg, and the trunk are affected on one side and the structures innervated by the third cranial nerve on the opposite side; and still another in which the parts supplied by the fifth nerve are affected on one side, causing sensory impairment on the same side of the face, while the motor power of the opposite limbs is affected. There is yet another kind of paralysis to be considered called "double hemiplegia," but this in itself is scarcely a separate variety, only a condition in which paralysis of one side has been succeeded by paralysis of the other, and on account of the affection being a two-sided one certain symptoms—especially the affection of what are known as bilaterally associated muscles—are produced, in many instances causing a close resemblance to bulbar palsy, so that certain cases of double hemiplegia are also spoken of as cases of "pseudo-bulbar paralysis." In this lecture I shall only just refer to the condition known as "functional" or hysterical hemiplegia—a condition in which, without any, at all events discoverable, lesion, the symptoms of hemiplegia due to organic disease are very closely simulated. I have thought it best, in order to obtain as comprehensive a view as possible of our subject, to divide the lecture into two main parts and to consider (1) the character of the paralysis, the relative weakness or disability produced in different parts of the body depending upon the position of the lesion in the brain; and (2) the nature of the lesion producing the paralysis as determined by the clinical history of the case. In conclusion, I shall show you several cases which will illustrate at least some of the points to which I shall refer.

As regards the character of the paralysis, in the ordinary form of hemiplegia there is weakness of one side of the face and trunk and of one arm and of one leg. It is not infrequently said that the paralysis of the face is of the lower part only, but the whole of the one side of the face is affected, although the weakness of the lower part is more obvious; in some cases of old hemiplegia it is hard to say that there is any facial paralysis. The weakness of the trunk on one side also is not as a rule very marked, although it is distinct enough, and the reason for this I shall refer to presently. In reference to the limbs, the arm is in the great majority of cases more paralysed than the leg. Why, then, with a lesion of one side of the brain causing paralysis of the opposite side of the body should the parts be affected in this way—namely, the face and trunk less than the limbs, and of the limbs the leg less severely than the arm? The explanation of this peculiarity is to be found in the hypothesis formulated in 1866 by Sir William Broadbent—a hypothesis which throws much light on obscure problems of cerebral physiology and pathology, and one to which clinical experience gives almost daily stronger support. This hypothesis is that bilaterally associated movements are represented on both sides of the brain, and the greater the strength of this bilateral association the more nearly equal is the representation on the two sides of the brain. Thus we know that the two lower limbs are much more closely associated in their movements than are the two upper. We

No. 4087.

very frequently use one arm quite independently of the other. A movement of one leg without some movement of the other is comparatively uncommon, and in the habitual use of the lower limbs for purposes of locomotion the association of the two is a very close one. The same applies even more strongly to the trunk movements. It is apparent that it is impossible for us to move one side of the abdomen or the chest without also moving the other. And so also with regard to the face. Facial movements in expression, &c., are nearly always bilateral. With regard to the forehead especially they are inevitably so; with regard to the eyes less so, although some people find it impossible to wink with one eye; and with regard to the lower part of the face—the part about the mouth—the association is still less close, although still much closer than that between the two arms or even between the two legs. Given, then, a lesion of one side of the brain causing paralysis of the opposite side of the body—the face, the trunk, the arm, and the leg—and situated at such a point (if such a point can be imagined) as to affect the face, the arm, the leg, and the trunk areas or fibres equally, we should expect to have the arm most affected, the leg less affected, the face still less, especially in its upper part, and the trunk least of all; and this, as I have already told you, is what actually happens in the ordinary form of hemiplegia. And I may just mention in passing that this hypothesis explains also the phenomena we meet with in double hemiplegia or pseudo-bulbar paralysis to which I have already referred. The symptoms by which this is allied to bulbar palsy are in the fact that swallowing and articulation are affected. The movements subserving those actions are strong in their bilateral association and consequently in their bilateral representation in the brain, so that a lesion of one side of the brain if it affects them does so only temporarily. But if, in addition to the weakness caused by a unilateral lesion, we have the weakness produced by a second lesion on the opposite side, it will at once be understood that considerable interference with these movements is not only likely but almost inevitable. And such is the case, and as a consequence we have deglutition and articulation so interfered with—to mention the two most prominent symptoms—as to give rise to a condition closely simulating true bulbar paralysis.

Let us now consider for a moment the position in which a lesion will be situated in the brain to cause such a condition as I have briefly sketched. Beginning with the cortex, we may have the lesion situated there, causing so great a loss of power on the opposite side of the body as we have alluded to and you will easily understand that the lesion would have to be one of very considerable extent. As the fibres of the motor tract proceed downwards and the area which they occupy becomes smaller and smaller they become more and more closely aggregated. There may be a lesion occurring at any part of their course. There may be one under the cortex, necessarily also a large one, or where the fibres are massed together in the posterior part of what is known as the internal capsule, a tract of fibres lying between the lenticular nucleus and the caudate nucleus and optic thalamus, and this is by far the most common situation. Or we may have the lesion in the crus cerebri or in the pons, or even lower down in the medulla, although in the latter case, if it is low enough—i.e., below the trunk and nucleus of the facial nerve—the face will escape altogether. But I have not seen a lesion so situated. In any of these positions a small lesion may be sufficient to cause extensive paralysis. In determining the position of a lesion it is necessary to remember that just as the centres for the different parts occupy a definite position in the cortex so the fibres have a similar definiteness at least as low as the crus. Thus in the internal capsule the face fibres are in front of the arm fibres, and those again in front of the leg fibres. And it may incidentally be mentioned that behind the leg fibres run the sensory fibres, and behind these again are the visual fibres subserving the two corresponding halves of the retina—i.e., the field of vision of the opposite side, so that a patient with a lesion in this position on the left side has right hemiplegia and cannot see to his right side—a condition known as "right hemianopia." Similarly in the crus the face fibres are internal to the arm fibres, whilst the leg fibres are external to those for the arm. In the pons the same division cannot be distinguished, for the fibres are now collected into several bundles without any, at all events discovered, topographical relation to function. You will also see that it is possible for a lesion to affect not the whole of the opposite side of the body but only a part, and

C C

then it will give rise to what is known as "monoplegia"—a small lesion in the leg area of the cortex, e.g., may cause only weakness of the opposite leg. It will scarcely cause complete paralysis by reason of the bilateral representation already referred to. A limited lesion in the arm area may, however, cause practically complete paralysis of the opposite arm alone. From the closer aggregation of the fibres lower down the lesion to cause a monoplegia would have to be an exceedingly small one, and as a matter of fact monoplegia from any lesion lower than the cortex, or just underneath it, is very rare for this reason.

We may have, then, an ordinary case of hemiplegia—we shall say "left hemiplegia" for reasons which will be obvious further on. Such a condition as that described may be due to a lesion in any of the places mentioned and without further symptoms it is impossible to say where. Sometimes, however, we find that the leg is more affected than the arm, that, for example, movement of the foot is completely absent while the hand can be moved. In such a case the face is as a rule slightly if at all visibly affected and the lesion will of course be one the focus of which is in the leg area of the cortex or among the leg fibres of the internal capsule or the crus. It is, indeed, a condition, as it were, midway between monoplegia and ordinary hemiplegia. In many cases, also, in which the leg is more affected than the arm there is anaesthesia of the paralysed side present and then the lesion is situated in all probability at the hinder part of the posterior two-thirds of the internal capsule. As we have already mentioned, the leg fibres are the most posterior of the motor fibres in the capsule and lying close to them are the sensory fibres. If, in addition to the anaesthesia, there is also hemianopia (loss of the corresponding half of the field of each eye) the probability of the lesion being of the hinder end of the capsule becomes a certainty, and conversely, where, in a case of hemiplegia you find hemianopia and hemianæsthesia, the leg, as a rule, is more affected than the arm.

I have hitherto purposely spoken of left hemiplegia, as there is frequently associated with paralysis of the right side the condition known as aphasia, in which the patient is unable to speak or perhaps even to understand what is said to him. According to current doctrines permanent aphasia is always due to a cortical lesion or to a lesion lying immediately under the cortex, and it is said that any lesion situated lower is not capable of causing at least permanent aphasia. The reason for this is said to be that speech processes can be conducted across through the corpus callosum and reflected down from the opposite hemisphere.

It is the rule with right hemiplegia to have some degree of aphasia. If there is none, then either the patient is left-handed or the lesion is situated at some distance from the speech centre and in such a way as not to interfere with the conduction of speech processes. Thus a lesion of the internal capsule may cause right hemiplegia without aphasia and even a cortical lesion may do so if the speech centre is not injured. If, for example, you have the focus of a unilateral cerebral lesion near the middle line it is quite likely that the third frontal convolution may escape, and Dr. J. Hughlings Jackson has for years been in the habit of pointing out that in cases of right hemiplegia without aphasia or with slight and transient aphasia the leg as a rule is more affected than the arm. I am able to show you to-day two cases illustrating this.

But besides these ordinary forms in which the affection of one-half of the body is all on the same side, a condition of crossed hemiplegia is met with, as I have already stated. The most common form is that in which the face on one side is affected and the limbs on the other. In such a case the lesion is situated in the lower part of the pons affecting the pyramidal tract before it has decussated and involving the fibres of the facial nerve as they pass from the nucleus to emerge as the facial nerve. The affection of the face in such a case is, as a rule, more severe than in ordinary hemiplegia and partakes much more of the characters of the paralysis known as "peripheral facial palsy" or "Bell's paralysis." In other words, the upper part of the face is much more affected than is usual in cerebral paralysis. The sixth nucleus also is often affected in such a case, and this will not be surprising when you think of the relation of such a lesion in the position I have described to this nerve and the close connexion of the nuclei of the sixth and seventh nerves. Similarly we may have hemiplegia in a patient associated with anaesthesia of the face, and in such a case also the lesion must be pontine, the anaesthesia being due

to affection of the fifth nerve or its nucleus. Sometimes in a case of hemiplegia, in other respects of the ordinary type—namely, affection of the face, the arm, the leg, and the trunk on one side—we have paralysis of the third nerve of the opposite side. Such a condition, if it is the result of only one lesion, can result from a lesion in only one situation—namely, in the crus cerebri of the side on which the third nerve is paralysed. It is a very uncommon form of hemiplegia.

We shall now proceed to the second part of the subject and consider how to determine the nature of the lesion causing hemiplegia, whether hæmorrhage, thrombosis, embolism, or tumour. The two factors to be taken account of in such consideration are the mode of onset of the paralysis and what may be called the clinical pathology of the individual, meaning by this the state of his arteries, pulse, heart, kidneys, and organs generally.

1. As regards hæmorrhage the onset of the paralysis is, as a rule, sudden and may take place during exertion. Perhaps one of the commonest forms of exertion with which cerebral hæmorrhage is associated is straining at stool. There is usually loss of consciousness, and if the hæmorrhage is a large one there may be profound coma with stertorous breathing or the irregular respiration known as Cheyne-Stokes respiration. If the hæmorrhage is superficial, that is cortical, the onset is usually signalled by a convulsion starting in the limbs opposite to the site of hæmorrhage and usually becoming universal. There may be a series of such convulsions the result of the cortical irritation. The pulse may be full and tense and the artery hard and obviously atheromatous. Healthy vessels do not readily rupture, whereas atheromatous ones do, and, besides, atheroma of arteries is not uncommonly associated with the presence on them of small aneurysmal dilatations. The heart also may be hypertrophied and there may be contracted kidneys. It does not necessarily follow that there will be albumin in the specimen of urine you may examine, but this does not exclude kidney change, and it is well to examine for the presence of vascular changes usually associated with kidney disease besides those already mentioned. The most important of these are the changes in the retina and its vessels, the condition known as "albuminuric retinitis," and I have known this frequently present in cases in which repeated examination has failed to reveal the presence of albuminuria.

2. The presence of these retinal changes is not absolutely conclusive that the condition giving rise to the symptoms is cerebral hæmorrhage, for it must be remembered that the condition of vessels which makes them liable to rupture is also that which tends to give rise to clotting in them and so induce the second condition which we have to consider as a cause of hemiplegia—viz., thrombosis. When this condition is present in the old the onset as a rule occurs during rest, often the rest which follows undue exertion. The commonest time of onset is during the night and the paralysis may only be realised when the patient gets up, or tries to get up, in the morning. Loss of consciousness may or may not take place—more frequently it does not; the pulse is slow and the condition generally not apparently one of such urgency and seriousness as in hæmorrhage. As will have been evident from what has already been said, visceral changes may be present similar to those mentioned as associated with hæmorrhage, for, as already stated, the atheromatous condition of the arteries renders them not only liable to rupture but also to become blocked. One thing is worth remembering, and that is that when the hemiplegia is on the right side and aphasia is present the cause is more likely to be thrombosis than hæmorrhage. The reason of this, from what has been said about the situation of the lesion in aphasia, will be apparent.

What I have said so far about thrombosis refers particularly to that condition as occurring in the aged. But hemiplegia is not confined to the aged, and in young adults or people generally under the age of 40 years in whom no heart disease or kidney disease is present hemiplegia is almost invariably due to thrombosis occurring in diseased vessels. The nature of such disease is the thickening which results from syphilis, and this is no doubt the usual condition giving rise to hemiplegia in those who have not reached the age at which senile atheroma may occur or in whom there is no cardiac condition likely to give rise to embolism or diseased vessels with kidney affection.

3. This leads us to the consideration of the third condition causing hemiplegia—viz., embolism. In embolic hemiplegia the onset is sudden, consciousness may or may not be lost,

and if it affects the right side aphasia—transitory it may be—is usually present. The sudden onset and the presence of obvious heart disease, especially of mitral stenosis, are usually sufficient to indicate the nature of the lesion, although even then the rule is not absolute, and I have known thrombosis occurring in an artery affected with endarteritis due to syphilis cause hemiplegia in a patient with mitral stenosis.

4. Another cause of hemiplegia is tumour and in this the clinical history is of immense importance. If there is or has been headache, sickness, and optic neuritis with unilateral weakness, of course the cause is almost certainly tumour, but you may justifiably diagnose tumour when not one of those so-called classical symptoms is present, if there is hemiplegia of slow onset—i.e., affecting first one limb slightly and gradually increasing its effect both in degree and in extent, the weakness occupying months or even longer before it can be definitely described as hemiplegia. If the tumour is situated beneath the cortex or in the vicinity of the central ganglia you may have only the slow onset to guide you; if it is in the cortex you may have in addition fits of local commencement and the hemiplegia may at first be only a temporary one occurring after the fits.

I need scarcely consider the question of abscess which may also cause hemiplegia. If abscess is present you will probably have a history of traumatism, or ear disease, or empyema, or suppuration in some other part. I have known, however, cases of abscess in which none of those were present and in which the clinical history and condition did not give rise to any suspicion that the cause was other than an ordinary vascular one. Yet in the great majority of cases of abscess you will have one of the three conditions I have mentioned—ear disease, suppuration elsewhere, or a history of injury.

I would just mention the hemiplegia which occurs in childhood. This may be of two kinds. 1. You may have a birth palsy hemiplegic in type, although in this form of paralysis the symptoms are usually bilateral. As the onset occurs during birth, usually in first-born children, and in cases in which the labour is long and difficult, often instrumental, and as the cause of it is meningeal hæmorrhage, you can understand that the affection is usually bilateral in its symptoms, the hæmorrhage extending on each side of the vertex. But you can also understand how the symptoms may be hemiplegic if the hæmorrhage is confined to one side of the vertex. 2. The other form of hemiplegia in childhood is the ordinary so-called infantile hemiplegia occurring in the early years of life, commencing usually with a unilateral fit or a series of convulsions. The cause of this is uncertain; according to some it is an inflammation of the grey matter, according to others a thrombosis in arteries, while Sir William Gowers believes that it is determined by a venous thrombosis. The hemiplegia is often severe, there is sometimes present the peculiar mobile spasm known as athetosis, and the patient is often subject to fits starting on the paralysed side. One point also is of interest, and that is that mal-development of the hemiplegic side nearly always results, so that it is smaller in every way than its fellow. I am able to show you an excellent example of this.

The treatment of hemiplegia divides itself into two natural parts—the treatment at the onset and the later treatment undertaken with the view of restoring function as much as possible. The great point in reference to the treatment at the onset is to determine the cause of the paralysis. If it is embolism, absolute rest, light food, and extreme care in avoiding any strain on the heart are the essentials; if it is hæmorrhage, free purgation, light, easily digested food, leeches to the temples if there is pain, and absolute rest are the main things; if it is thrombosis in the old, gentle aperients, together with cardiac stimulants and liquid nourishment, are best; if thrombosis in the young, then mercury and iodide of potassium must be energetically administered. It is unnecessary to go into the subject of the treatment of tumour or abscess. Anti-syphilitic remedies or operation are the only means open for the former, operation for the latter is the only treatment to be considered. Treatment in the later stages is directed to improvement of the condition. Loss of power and rigidity are the two things to be considered. Gentle rubbing is certainly useful in overcoming the rigidity, faradisation applied to the extensors—e.g., of the forearm—may diminish the flexor spasm and will also exercise the affected limbs. Fresh air, gentle exercise, and light, easily-digested food are the other means for securing the best results.

## A Clinical Lecture

ON

### THE EARLY DIAGNOSIS OF PULMONARY CONSUMPTION, WITH ESPECIAL REFERENCE TO THE VALUE OF TUBERCULIN.

*Delivered at the Brompton Hospital for Consumption on Nov. 6th, 1901,*

By ARTHUR LATHAM, M.A., M.B. OXON.,  
M.A. CANTAB., M.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO THE HOSPITAL, AND TO ST. GEORGE'S HOSPITAL.

GENTLEMEN,—I make no apology for discussing with you this afternoon the grounds upon which we are justified in making a positive diagnosis of early pulmonary consumption, more especially as I hope to bring under your notice a method of diagnosis which has been strangely neglected in this country—namely, the use of Koch's *old* tuberculin. The early diagnosis of tuberculosis is a question of supreme importance, perhaps the most important that the physician has to face, as anyone must realise when he grasps the facts that one person out of ten dies in this country from this disease, that a large proportion of those who die from other diseases are afflicted with consumption in one or other of its forms, and that in the early stages we can, owing to our greatly increased knowledge of the pathology and treatment of the disease, almost certainly bring about complete arrest of the tuberculous process, whilst in the later stages our efforts must often be largely palliative. I am not, I think, making too strong a statement when I assert that the larger number of cases of pulmonary tuberculosis, which are undetected in the early stages, end fatally within three or four years from the first onset of the disease. There can, therefore, be no question as to the importance of the disease being detected at the earliest possible stage.

I have here 15 or more patients who are in an early stage of consumption, but before you examine them I will briefly refer to the methods we employ to arrive at a *definite* diagnosis in the early stages of this disease. There are, fortunately, several ways in which we can achieve our object. We are, I think, justified in making a positive diagnosis in the vast majority of cases under the following circumstances.

1. When we find diminished resonance and increased resistance to the finger associated with the presence of *persistent* crepitations or fine râles in those situations in which tuberculosis usually starts in the lungs—namely, the apices of the upper lobes, more especially towards their posterior aspect. For example, the year before last I saw a patient at Sawston with Mr F. Edwards. She was well nourished and there was no family history of tuberculosis or history of exposure to infection; she had enjoyed previous good health, save that she had been troubled for a few months by a dry hacking cough. There was no loss of weight and no rise of temperature. The sputum had been examined on several occasions, but no tubercle bacilli were found. On physical examination I found slightly diminished resonance and increased resistance to the finger, together with feeble respiration and a few crackles at the end of inspiration above the left clavicle and to a less extent in the left supra-spinous fossa. The other portions of the lungs were healthy. I made a positive diagnosis of tuberculosis notwithstanding the absence of tubercle bacilli and the patient regulated her life in accordance with that opinion. She is now practically well, the only signs present being slight dulness and diminished breath sounds at the left apex, together with definite though slight contraction in that position—signs, that is, of a healed tuberculous lesion.

If there is no diminished resonance we cannot make a positive diagnosis, for we meet with cases in which there is no alteration of the percussion note but such physical signs as diminished breath sounds and fine râles, associated perhaps with slight fever. These râles eventually clear up and are probably due to local catarrh of the smaller tubes. Nor, again, can we make so positive a diagnosis in the absence

of tubercle bacilli in the sputum when there is dulness with adventitious sounds in some other situation than the apex of the lung. It is, of course, not so very uncommon to find the first physical evidence of pulmonary tuberculosis either at the bases of the lungs, or in the neighbourhood of the nipples, or in the axillary regions, but in these situations other conditions may occasionally give rise to the same physical signs as early tuberculosis, and we are not justified—at any rate, for some little time—in making as positive a diagnosis as we are when the apices are affected.

2. When the symptoms are suggestive of tuberculosis and tubercle bacilli are present in the sputum, although, on a physical examination, the lungs are apparently sound. Many patients come to a hospital like this who are apparently in good health, but who complain of repeated attacks of what they term “influenza,” or of a great tendency to “catch cold”; or, again, patients come with a history of some previous lung trouble and subsequent wasting; or people with a strong tuberculous history who are themselves anæmic and troubled by a distressing cough. In many of these cases it is impossible to make a definite diagnosis one way or the other from the physical signs present, and consequently I always have the sputum examined for tubercle bacilli. If bacilli are found the diagnosis is certain and the patient must act accordingly, and we may confidently assure him that if he can but carry out the necessary treatment in all its details he will be able to throw off the disease to all intents and purposes. Some few years ago a personal friend of my own, under the care of Dr. H. Menzies, although in apparently good health, was constantly having slight attacks of what appeared to be a feverish cold. There was no family history of tuberculosis, and on examination of the chest there were no physical signs of any disease. The attacks continued and it was thought wise to examine the sputum. Tubercle bacilli were found and the patient was persuaded with some difficulty to give up his work and to devote his attention, for a time, entirely to his health. He is now in a much better condition; his weight has increased one and a half stones, whilst the only physical signs present are those of fibrosis and contraction of the right apex.

3. When hæmoptysis, even to such a small extent as a teaspoonful, occurs in cases where there is no evidence that the bleeding comes from the upper air-passages or is dependent upon some morbid condition of the heart or other disease within the chest. We must be careful not to overlook some trivial cause, such, for example, as Dr. William Murray<sup>1</sup> with a courage too seldom seen in our profession confesses to in the following extract from his book:—“A gentleman, whose name is now a household word throughout the world, called on me in great alarm on account of an attack of blood-spitting. I saw a good deal of blood on his handkerchief, and on examining his chest I heard, or thought I heard, rough breathing and fine crepitation over the left apex. I told him this and treated him accordingly. On going to his shop he ..... looked into his mouth and discovered that the bleeding was from a spongy gum which he had doubtless lacerated with his tooth-brush. I need not say that he lost confidence in me and I lost my patient.” Hæmoptysis in some cases is associated with suspicious or even definite physical signs, with a strong family history of disease, but in many cases it is the first symptom of pulmonary tuberculosis; it often occurs in persons of apparently robust health and is frequently unassociated with the presence of tubercle bacilli in the sputum. I have at present under my care a lady who five years ago spat up on three occasions a teaspoonful of blood. I examined her carefully at the time to see if the blood had any possible source save the lungs, but found none. There was no family history of tuberculosis and the patient had had no previous illness. The only physical sign which I could detect was a slight persistent pleuritic creak in the left supra-spinous fossa. I endeavoured to convince this patient of the importance of looking after her health seriously for a somewhat prolonged period of time, but was only able to persuade her to take small doses of cod-liver oil. With this exception she lived her usual life. The physical signs made very slow progress until the end of last year, when she had a smart attack of bronchitis; in consequence of this the tuberculous mischief extended a little, and Sir R. Douglas Powell and myself were then able to convince the patient that she was really ill. She went on our advice to Dr. Walther's sanatorium at Nordrach, where she gained nearly two stones in

weight, whilst the physical signs now present are those of chronic fibroid disease. Her condition is satisfactory, but I am certain that if she had been willing to undergo treatment at an earlier stage she would have been, to all intents and purposes, an absolutely healthy person to-day. In another case which I saw with Mr. R. C. Gayer in Kensington last year there was profuse hæmoptysis associated with a strong family history of tuberculosis. There were no physical signs save a few crepitations beneath the right clavicle, which I thought were possibly due to the recent hæmoptysis, but which persisted for some considerable time and were no doubt due to the disease. There was no other cause for the bleeding, so Mr. Gayer and I took the responsibility of advising this patient to spend the winter at St. Moritz, although this involved an entire change of his plans and, indeed, of his life. At St. Moritz he gained over a stone in weight, and when I saw him this summer he looked an entirely new man, whilst the only evidence of disease that we could find was a deficient entry of air with very slight dulness over the right clavicle. In a third case which I saw with Mr. J. S. E. Selby at Waddesdon there was hæmoptysis so profuse that the patient became almost pulseless, but there was no physical sign of disease or family history of tuberculosis, and no bacilli were present in the sputum. There was no other cause for this alarming symptom, whilst the patient was decidedly tuberculous in aspect. Here again I advised that at least a year should be devoted to the patient's health, although such a procedure was highly inconvenient. I have recently heard from Mr. Selby that the great improvement which has followed in this case more than justified our advice.

I have enlarged on the significance of the expectoration of blood because I do not think that medical men are sufficiently ready to accept the responsibility of making a definite diagnosis on this symptom alone. Naturally we must be certain that there is no other cause for the bleeding, but if we find none, then, unless we insist on a rigorous course of treatment at once, our patients lose their best opportunity of getting well and come back later with well-marked signs of consumption.

4. When there are suspicious signs in the lungs, with tuberculous disease elsewhere in the body. For instance, I saw at the end of last year with Mr. Herbert Allingham a young man who had previously had one of his knee-joints excised for tuberculous disease and in whom Mr. Allingham had recently opened an abscess in connexion with the spinal column. When I saw this patient he was complaining of cough and a little pain in the right axilla. On examination I found a few scattered crackles in the right axilla and at the right base. There were no tubercle bacilli in the sputum, but the physical signs persisted. This patient on our advice went out to New Zealand, and I have lately seen a photograph of him showing that his improvement has been great, apart from the facts that he has increased in weight, lost his cough, and is able to go about in comfort.

When we meet with such signs or symptoms as I have mentioned it is imperative for us to treat the patient, on the well-known lines, for pulmonary tuberculosis. Unfortunately, however, we are constantly seeing cases of early consumption in which the symptoms or physical signs do not warrant a positive opinion. For example, we meet with cases in young people of progressive wasting when there is no malignant disease or diabetes to account for this symptom; with cases of general ill-health associated with pain in the chest or occasional attacks of so-called influenza or feverish cold; or patients may come to us suffering from slight cough, anæmia, and possibly feeble digestion; or again we see cases in which there is a history of pneumonia, pleurisy, or some other lung trouble, with subsequent debility and ill-health. In all such cases there may be in addition a strong history of tuberculosis, and yet on examination we may find no physical signs whatever and no tubercle bacilli in the sputum. On the other hand, we may find certain indefinite physical signs. We may find, amongst other things, the dilated venous radicles over the spinous processes to which Dr. W. Overend<sup>2</sup> has recently called attention; definite myotatic irritability, together with an increased pulse-rate; commencing depression or flattening in the region of one or other clavicle or supra-spinous fossa, or diminished freedom of costal movement; slight increase of the vocal and tactile vibration; slight diminution in the clearness and duration of the percussion note or slight increase in the resistance to the fingers; diminution of the

<sup>1</sup> Rough Notes on Remedies, p. 84.

<sup>2</sup> THE LANCET, August 31st, 1901, p. 592.

respiratory murmurs, prolongation and slightly higher pitch of the inspiratory and more especially the expiratory murmur, or jerky movements; or, again, there may be an occasional slight crepitation without any other sign. Our difficulty is increased when we remember that many of these signs occur in healthy individuals under certain conditions, more especially at the apex of the right lung. In such cases, then, we have perhaps general ill-health, a strong family history of tuberculosis, and certain symptoms and physical signs which make us strongly suspicious of consumption; yet we cannot give the dogmatic opinion which may be needed to save the patient's health. Take, for instance, the case of a medical man who consulted me last year. Two years previously he had suffered from pneumonia of the right lung, from which he made a good recovery. There was a fairly strong history of tuberculosis in his family and for a few months before I saw him there was considerable loss of weight, with slight harassing cough and scanty expectoration which on repeated examination was found to be free from tubercle bacilli, whilst on physical examination I found at the right apex, above the clavicle, and especially in the right supraspinous fossa, a diminution of the respiratory murmur which persisted when he coughed. Or, again, take the case of a medical student whom I saw this year. This patient was one of a family several of whom had suffered from one or other form of tuberculosis; he was wasting, very anæmic, and he suffered from slight cough. There was no fever at any time, and no tubercle bacilli were present in the sputum. On examination I found slight flattening above the right clavicle with prolongation of the expiratory murmur, and on two occasions I heard a faint click at the end of inspiration. This patient spent the summer, practically speaking, in the open air. He gained considerably in weight, but he still has signs at the right apex, which in view of his family history and general condition are not free from suspicion. Or take the case of a young man whom I have lately seen with Dr. Rashleigh. Here there was a history of pleurisy five years before, but of subsequent good health. The patient had recently become anæmic and was troubled by a slight cough with scanty expectoration in the morning. There was a certain amount of wasting and the digestion was impaired. Tuberculosis was strongly marked in the family. On examination I found in the right axilla a certain number of crepitations which were probably due to the attack of pleurisy; at the right apex the respiratory murmur was deficient on ordinary respiration, and, on deep respiration, the expiratory murmur was prolonged. The sputum contained no tubercle bacilli, but diplococci pneumoniæ were present in large numbers.

What are we to say in such cases as these if, after repeated examination of the sputum, or even if by means of inoculation, we are unable to demonstrate the presence of tubercle bacilli? If we say that there is no definite evidence of tuberculosis our patients are apt to be careless and to forget that even if they are not suffering from this disease they are extremely likely to contract it. On the other hand, we are not, I think, acting rightly if we assert that tuberculosis is present and order our patients' lives in accordance with this opinion. In many suspicious cases the patients get quite well on simple treatment. For instance, I remember very well the case of a young woman whom Mr. Herbert Allingham, who had seen her for some surgical trouble, advised to consult me three years ago. She was anæmic, was losing weight, and was suffering from cough and slight expectoration, together with impairment of digestion. On examination I found that the cough might be accounted for by the condition of the throat, but that there were distinct bronchophony and impaired note at the right apex, together with marked prolongation of the expiratory murmur. I prescribed a simple remedy in the shape of aloes and iron, and am glad to say that at the present day there are no suspicious signs in the chest, while the patient's condition is very good.

The majority, however, of these cases do not improve in this way, and we are in need of some means of determining their true nature, so that if we find no tuberculosis we can adopt measures which in a few weeks or months will restore the patient to health; whereas if we find definite evidence of tuberculosis we can insist on our patients taking the necessary steps to arrest completely the disease. My experience is—as might be expected—that if a patient cannot get a definite opinion that he has tuberculosis he will not take any great care of himself, but that if we are able to

state positively that tuberculosis has definitely set in, and that the chances of cure are extremely hopeful, then patients will make very great sacrifices. We are, I think, able to do this, and have at our disposal the means of determining the true nature of these suspicious cases by the employment of Koch's old tuberculin as a diagnostic agent, provided that it is used under certain definite conditions and by a skilled observer.

Several other methods have been employed to facilitate the diagnosis of consumption, such as the x rays and the agglutination of tubercle bacilli by means of the patient's serum, but none of these are at all reliable in the early and indefinite stages of the disease, and are not to be compared with tuberculin. This latter agent fell into disrepute very soon after Koch's somewhat premature disclosure, chiefly owing to the fact that Virchow asserted that tuberculin injections, in some cases, tended to generalise the disease. Virchow's statement was upheld by a report of eight physicians of this hospital, which was signed by Dr. C. Theodore Williams and Dr. John Tatham, and there can be no doubt that given in the doses and in the class of case in which it was given in the early days tuberculin was a dangerous weapon. I would point out, however, that the larger number of cases treated when the discovery was first made were cases of advanced disease with secondary infection, in which febrile symptoms were present, and that tuberculin was given in frequently repeated and often large doses. In the class of cases in which I use this remedy there is no fever, no advanced disease, or secondary infection, whilst the amount I use is small, and the injections never exceed three, or at most four, in number. I never use it where there is evidence of much disease. For instance, I do not use it to find out whether an attack of general bronchitis is tuberculous or not, or to make a diagnosis between bronchiectasis and tuberculosis. If the physical signs point to extensive mischief and I am in doubt whether the disease is tuberculous I do not use tuberculin because of the experience of Virchow and my colleagues. Nor do I use it when I am certain of my diagnosis by other means. For example, I admitted a young man who is here to-day a few weeks ago into St. George's Hospital. I had then seen him on several occasions and was suspicious of tuberculosis as he was anæmic and constantly "catching cold." The only physical signs that I found were diminished resonance, slight wasting, and deficient entry of air at the left apex. It was my intention to inject him with tuberculin, but before doing so I again examined his chest—I had not seen him for a couple of months—and found that in addition to the above signs and symptoms there were a few crepitations at the end of inspiration over the left clavicle. These persisted and I was consequently able to make a definite diagnosis without injecting him.

When the disease is so slight that a diagnosis cannot be made on physical signs nor any tubercle bacilli demonstrated in the sputum, then I believe that one, two, or three small injections of Koch's old tuberculin are absolutely free from danger. There is no recorded case where, used in the way in which I use this drug, any bad results whatever have followed the injections, and that is the experience of Koch, of Brierger, and Neufeld,<sup>3</sup> of B. Fränkel,<sup>4</sup> of Dr. Heron,<sup>5</sup> and of myself. Again, Professor Osler<sup>6</sup>—a man of singularly wide experience and level judgment—in taking part in a discussion raised by Dr. Heron at the recent British Congress on Tuberculosis, which was chiefly concerned with the curative value of the newer forms of tuberculin, said that he regarded the old form of tuberculin as a safe and efficient diagnostic agent, and that he used it as a routine practice in the wards at the Johns Hopkins Hospital. I think, then, that we may rest assured that under the conditions which I have laid down—that is, in the absence of definite signs of extensive disease, in the absence of fever, and in small doses—there is no danger whatever in the use of tuberculin as a diagnostic agent in the early stages of consumption.

We now have to consider what is the value of a reaction following the use of tuberculin. If we obtain a reaction can we assert that the case is one of tuberculosis? And again, if we fail to obtain a reaction after three, or possibly four, injections, can we positively exclude tuberculous disease?

<sup>3</sup> Deutsche Medicinische Wochenschrift, February, 1900, p. 93.

<sup>5</sup> Brit. Med. Jour., July, 1901, p. 213.

<sup>6</sup> Ibid., p. 214.

With regard to the first question Goldschmidt,<sup>7</sup> Babes, and Kalendero<sup>8</sup> have obtained a reaction in cases of leprosy. Netter stated that he obtained the reaction in 27 out of 100 cases where the patients were afflicted with other diseases than tuberculous disease of the lungs. Straus and Teissier<sup>9</sup> have observed a reaction in syphilitic subjects, and so on. With regard to leprosy we might perhaps expect a reaction; in any event it does not complicate the cases which we are concerned with. In the other diseases in which tuberculin is stated to have given a reaction there is not sufficient proof, in the shape of post-mortem or other evidence, to show that the patients in these cases did not also suffer from tuberculosis. Klebs, jun.,<sup>10</sup> states that he obtained a reaction in every case of chlorosis, but this is the experience of no other observer and requires confirmation. Against these statements we have Koch's<sup>11</sup> assurance that, after an experience of some 3000 cases, he considers the tuberculin test to be almost absolute, and we have in addition the evidence gained from post-mortem examinations of cattle slaughtered after a tuberculin reaction has been obtained—evidence which shows us how extremely uncommon it is for tuberculosis not to be present in those cases in which a reaction has been obtained. Do we ever fail to obtain the reaction when tuberculosis is present? Cornet<sup>12</sup> in his book upon this subject refers to a few cases in which tuberculosis was certainly present but which gave no reaction when tuberculin was injected; J. M. Anders<sup>13</sup> of Philadelphia, who is a firm believer in the diagnostic value of tuberculin, has seen cases in which there was no reaction, although post-mortem examination showed the presence of tuberculous lesions; Knopf<sup>14</sup> also considers that tuberculin may fail to show the presence of disease in some instances. This, however, merely means that the negative value of no reaction is not as great as the positive value of a definite reaction. We have no absolute certainty in medicine, and must always remain satisfied when an overwhelming majority of cases give a particular sign or symptom, and in this respect we may compare the tuberculin reaction very favourably with what is known as Widal's reaction.

The following is the method which I employ in utilising the tuberculin test. The old tuberculin of Koch—which is free from tubercle bacilli—is diluted with a 0.5 per cent. carbolic acid solution, so that a 1 per cent. solution of tuberculin is obtained. No more of the dilution should be prepared than is likely to be sufficient for the requirements of a few days, and as soon as the solution becomes at all turbid it should be thrown away. The temperature—preferably of the rectum—is taken every four hours for three days before the injection is made, and if there is any appreciable fever the injection must be put off for a time. The injection, according to the experience of Dr. S. Vere Pearson, late house physician at this hospital, gives rise to less inconvenience when made in the loin than it does if made in the arm or abdomen. The temperature must, of course, be taken after the injection is made every four hours as before.

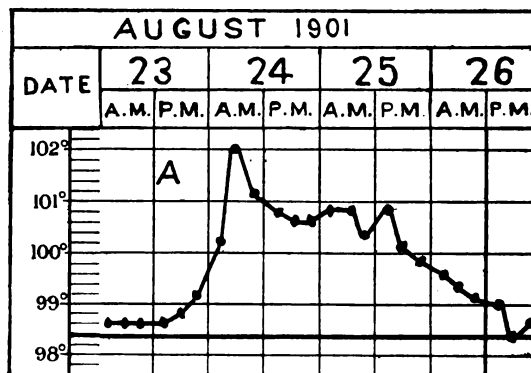

With regard to the amount of tuberculin used, my object is to inject just sufficient to cause a rise of temperature—that is, I try to avoid causing a greater rise than is absolutely necessary. If the patients are what may be described as weaklings, or if the signs are extremely suspicious, I commence with 0.001 cubic centimetre of tuberculin in the case of adults (0.0005 cubic centimetre for children)—that is to say, one milligramme or half a milligramme; this is most safely accomplished by using a syringe of one cubic centimetre capacity and injecting a tenth part of the 1 per cent. solution of tuberculin which it contains. A rise of temperature of 1° F. may be considered to be a positive reaction; it is important to remember that this may, under exceptional circumstances, be delayed for 36 hours. If no reaction follows I wait three days and inject five milligrammes (for adults), though if there has been some oscillation of temperature but no definite reaction after the first injection three milligrammes may be sufficient. If there is still no reaction I again wait three days and then inject one centigramme (for adults); if there is no reaction now tuberculosis can be excluded. In cases

in which the patients are more robust, or in which the symptoms and signs are more indefinite, I use larger injections—five milligrammes for the first, one centigramme for the second, and two centigrammes for the third. Patients must be kept in bed after the injection until the reaction has passed off—that is to say, for about from 24 to 48 hours.

I will pass round the charts of three cases in which injections of tuberculin have been employed and hope to give you an opportunity afterwards of examining the patients themselves. For the notes of these cases I am indebted to Dr. Vere Pearson and Dr. Crompton, who acted as my house physicians when I had charge of Dr. Hector Mackenzie's wards this summer.

CASE 1.—The patient was a man, aged 26 years. He complained of cough, with wasting and weakness for one year. He had an attack of pleurisy three months before admission. The physical signs were as follows. On the right side: in front expiration was a little prolonged and high-pitched, at the apex and in the supra-clavicular fossa an occasional click was heard which disappeared after coughing. On the left side there was diminished resonance in front, and the breath sounds, more especially behind, were prolonged and high-pitched. There were no tubercle bacilli in the sputum. On August 23rd 0.005 cubic centimetre of tuberculin was injected at noon. At 8 o'clock next morning the temperature rose to 102° F., but it gradually fell and reached the normal on the 26th. A positive diagnosis of tuberculosis was then made (see chart, Fig. 1).

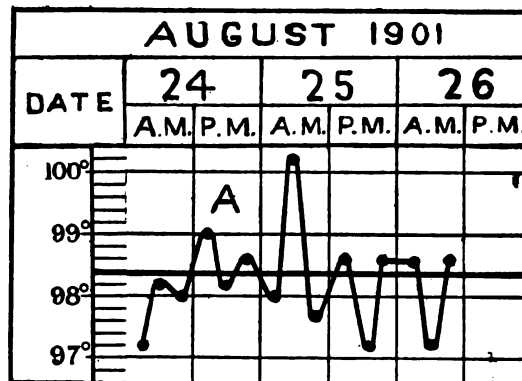

FIG. 1.

A (August 23rd), Injection of 0.005 cubic centimetre of tuberculin.

CASE 2.—The patient was a man, aged 45 years. His health had been indifferent. He had had an attack of pleurisy in 1893. The physical signs were as follows. The resonance to percussion was slightly impaired in

FIG. 2.

A (August 24th), Injection of 0.005 cubic centimetre of tuberculin.

the left infra-clavicular fossa, first and second spaces. The spine of the left scapula was less resonant to direct

<sup>14</sup> Nineteenth Century Practice of Medicine, vol. xx., p. 235.

percussion than was that of the opposite side. Expiration was a little harsh and prolonged in the supra-spinoous fossa. Nothing else abnormal was found in the lungs. No tubercle bacilli were found in the sputum. 0.005 cubic centimetre of tuberculin was injected on the evening of August 24th and in less than 24 hours the temperature had reached 100.4° F., becoming normal once more within 12 hours. A positive diagnosis of tuberculosis was therefore made (see chart, Fig. 2).

The following case is of interest in that it shows the value of tuberculin in excluding tuberculosis.

CASE 3.—The patient was a man, aged 57 years. He had had pleurisy 18 years ago, otherwise he was well till 1898; since then he had suffered from a cough, shortness of breath, and dyspepsia. The physical signs were those of general emphysema. In addition the apices of the lungs were not free from suspicion of tuberculous disease. The percussion note was impaired at the left apex, the inspiratory murmur was high pitched; vocal resonance was somewhat increased in both infra-clavicular fossae, and there were fine râles, especially at the left apex. No tubercle bacilli were found in the sputum. On Sept. 1st 0.005 cubic centimetre of tuberculin was injected, but there was no reaction at all. On Oct. 14th, as the man's condition was somewhat worse and the cough was more frequent, a further examination of the sputum was made, and a report was returned that numerous tubercle bacilli were present. Dr. Mackenzie viewed the report with suspicion, and on the 23rd he again injected 0.005 cubic centimetre of tuberculin and again failed to get a reaction. The sputum had been repeatedly examined since Oct. 14th but no tubercle bacilli had been found, and there seemed to be no doubt that owing to some mistake on the part of a hospital porter the report of Oct. 14th was not based on the sputum of this patient. A further injection of 0.01 cubic centimetre of tuberculin was given on the 30th, but no reaction followed. Tuberculosis was therefore excluded in this case (see chart, Fig. 3).

FIG. 3.

A (Oct. 23rd), Injection of 0.005 cubic centimetre of tuberculin. B (Oct. 30th), Injection of 0.01 cubic centimetre of tuberculin.

These few cases are, I think, sufficient to show you the value of this method and I will not trouble you by further details. To conclude, in my deliberate opinion we have in Koch's old tuberculin a most valuable means at our disposal for making a positive diagnosis in a large number of cases, which present suspicious symptoms and signs, at a much earlier stage of the disease than we can by any other means. We are thus enabled to impress upon our patients the vital importance of living under suitable conditions and amongst ideal surroundings and to place them on the road to an almost certain arrest of their disease.

## THE DIFFERENTIAL DIAGNOSIS OF SMALL-POX.<sup>1</sup>

By J. MACCOMBIE, M.A., M.D. ABERD.,  
MEDICAL OFFICER AT THE BROOK FEVER HOSPITAL.

WHEN I was asked to read a paper on small-pox to the Hunterian Society it appeared to me that the differential diagnosis of that disease would be a subject of interest to the members of the society, and that perhaps my observations might prove helpful to those whose opportunities of observing small-pox have been limited. The diagnosis of

small-pox presents difficulties, first, in the pre-eruptive stage and, secondly, in the eruptive stage.

### THE DIAGNOSIS OF SMALL-POX IN THE PRE-ERUPTIVE STAGE.

In the pre-eruptive stage difficulties often occur in connexion with prodromal rashes which may simulate scarlet fever and measles. Prodromal rashes resembling scarlet fever are usually best marked on the trunk, the abdomino-crural triangle—a triangle the base of which is on a level with the umbilicus and the apex about eight inches below the symphysis pubis—and the flexor surfaces, and they simulate scarlet fever closely in punctate appearance; but the absence of eruption for the most part on the extensor surfaces, the face, the neck, and the temples, and the exemption from faucial inflammation and submaxillary glandular enlargement, should warn one off a diagnosis of scarlet fever, especially if backache be a pronounced symptom. In other cases there is a copious crop of petechiae in the abdomino-crural triangle and other flexures. Now, in scarlet fever petechiae are rarely noted in the abdomino-crural triangle; more often they appear in other flexures.

Some hæmorrhagic cases of small-pox show a vivid red erythema involving the whole of the skin of the trunk and the limbs, with petechiae in the abdomino-crural triangle and other flexures, and deep purple or black subcutaneous hæmorrhages appear similar to those noted in purpura. Such cases are not infrequently diagnosed as scarlet fever, especially before the appearance of the flexure petechiae and purpuric spots. The eruption is not at first punctate, like that of scarlet fever, but may quickly assume a pseudo-punctate character on the groins and other flexures owing to the appearance there of crops of small, deep red petechiae. The faucial symptoms are unlike those of scarlet fever, and the initial symptoms of small-pox are usually well-marked, especially the lumbar pain; but in the earlier stages of these rashes the diagnosis is extremely difficult, and even those with special knowledge of infectious diseases may make a mistaken diagnosis.

The prodromal rash that resembles measles counterfeits very closely the eruption of that disease. It disappears on stretching the skin, but it is only slightly, if at all, raised, and therein lies the great difference between it and measles. It reaches its height within 24 hours of its appearance, and fades quickly, either before or soon after the appearance of the characteristic eruption of small-pox. The eruption envelops the whole skin more quickly than does that of measles, and in most instances it is not preceded by catarrhal symptoms; not infrequently, however, there is considerable conjunctival suffusion.

A valuable aid to the differential diagnosis of small-pox in the initial stage and measles is the presence or absence of Filatow's spots; if these be present the case is in all likelihood one of measles. Filatow's spots are situated for the most part on the buccal mucosa opposite the molar teeth, and less markedly on the mucosa opposite the other teeth. They are very small, raised, whitish dots, of about the size of a small pin's head, generally on a reddened base. They are usually discrete, but sometimes a confluent patch is seen. They appear in the majority of—some observers say all—cases, and they disappear usually within one or two days of the appearance of the eruption. Be it remembered that I am speaking of the pre-eruptive stage of small-pox, because in the eruptive stage the eruption of small-pox on the buccal membrane might possibly be erroneously regarded as Filatow's spots. These are, however, much smaller than the buccal small-pox spots, and they are arranged for the most part on the mucosa opposite the teeth and gums, whilst the spots of small-pox are distributed generally, more particularly affecting the palate, fauces, pharyngeal walls, and tongue.

In addition to these prodromal rashes there are many erythemas affecting circumscribed areas of the skin, and in appearance these often simulate scarlet fever and measles. I have little time to speak of these, though they afford valuable aid to the diagnosis of small-pox. I may say, however, that circumscribed punctate prodromal eruptions showing on the groins, the sides of the trunk, or the lumbar regions, or on the flexures of the arms and legs, or morbilliform or patchy non-punctate erythema affecting usually the extensor surface of the arms, the hands, the legs, or the feet, if the initial symptoms of small-pox be present, are often sufficient warranty for suspecting the onset of small-pox and for taking measures accordingly. It is important to remember that

<sup>1</sup> A paper read at a special meeting of the Hunterian Society held on Nov. 5th, 1901.

small-pox prodromal rashes are extremely rare in persons under 10 years of age, whilst the majority of cases of scarlet fever and measles occur under that age.

*Erythema multiforme* may cause difficulty. Usually initial symptoms resembling those of small-pox are absent. When present it is desirable to keep the patient under observation till the third or fourth day of disease, when the diagnosis will be rendered certain by the appearance or non-appearance of the eruption of small-pox.

*Typhus fever*.—At first sight it does not appear likely that this disease would be mistaken for small-pox, and if the observer will recollect that in typhus fever the eruption usually appears on the fifth day of disease and that it is not raised a mistaken diagnosis should not occur.

*Influenza*.—Only severe cases of influenza will be mistaken for small-pox, and then the prostration is perhaps more complete from the first than in small-pox. Pains behind the eyes and pains in the limbs are usually very pronounced symptoms in influenza. If an erythematous eruption be present the diagnosis is obscured, but the non-appearance of small-pox papules on the third day of the disease should clear up the diagnosis.

*Ptomaine* rashes from shell-fish, &c., are not unlike morbilliform erythemas of small-pox; but the absence of backache, with the history of rash appearing concurrently with the onset of the symptoms and inquiry as to diet, should obviate any mistake.

*Rötheln and copaiha rashes and liohen*.—In these the initial symptoms of small-pox are absent.

*Lumbago*.—In this condition the absence of pyrexia and headache should be sufficient to exclude the diagnosis of small-pox.

#### THE DIAGNOSIS OF SMALL-POX IN THE PAPULAR AND VESICULAR STAGES.

Here it is desirable to enumerate the prominent initial symptoms of small-pox and to describe the eruption thereof. The prominent initial symptoms of small-pox are headache, lumbar pains, often rigors, anorexia, vomiting and malaise, and pyrexia. The duration of these symptoms before the eruption of small-pox appears is usually 48 hours. And these initial symptoms are usually equally pronounced in vaccinated and in unvaccinated subjects, and in mild and severe cases alike. The modification of the disease caused by vaccination does not appear until the eruptive stage. In unvaccinated patients the eruption is in its very earliest stages macular. The macules speedily become papules, and are then hard and raised, and in the course of 24 hours have a distinctively shotty feeling, and show commencing vesiculation. The eruption takes from one to three days to come fully out, the length of time depending upon the abundance of the eruption. The vesicles increase in size, and at the end of five days they attain their full growth, when they are round and of about the size of a small pea with flattened top, and they mostly show depressed centres. They are of pearly appearance and are filled with clear serum. They are multilocular and do not collapse when transfixd with a needle. In the pustular stage many of the pustules become dome-shaped instead of being flat or depressed.

The eruption of small-pox in vaccinated subjects is macular or papular at first, and within a few hours of its appearance much of it is distinctly shotty. Some of the papules may show minute vesiculation at the end of the first day, and on the second and third days the vesicles have often reached their full growth. They are circular, often small, and generally more or less conical—not flattened or depressed, or showing only a minute depression. On the face the vesicles may be irregular in outline and not unlike spots of acne, but they do not show a central dot. The vesicular fluid is at first clear, but on the second and third days it becomes opaque, and many of the vesicles desiccate with no further evidence of pustulation; many of the papules never become vesicles. In other cases the eruption approaches more nearly to the eruption of small-pox as seen in unvaccinated subjects; but in a large proportion of cases of small-pox in vaccinated subjects the evolution of the eruption is more rapid than is the case with the eruption in unvaccinated subjects. The distribution of the eruption in both vaccinated and unvaccinated subjects is as a rule most abundant on the face and extremities, less so on the trunk, and usually there is more eruption on the back than on the chest and abdomen. The eruption is generally present on the palate, the fauces, and the tongue, and usually in

direct proportion to its abundance elsewhere. The temperature is high in the initial stage, but it begins to fall shortly after the appearance of the eruption, and when the eruption is fully out in most cases it falls to normal; in severe and confluent cases, however, it may not fall under 100° F.

The diagnosis of small-pox in the eruptive stage is often extremely difficult, consequently many mistakes occur, cases of small-pox being diagnosed as some other disease—very often chicken-pox or measles—and cases of other diseases being diagnosed as small-pox.

*Chicken-pox*.—The disease most frequently mis-diagnosed for small-pox in the eruptive stage is chicken-pox. In this disease the absence of initial symptoms is in striking contrast to their presence in small-pox. In a very few cases, however, especially in adults, there may be initial symptoms of backache, malaise, and some pyrexia, lasting from 12 to 48 hours, and followed by eruption. These are most exceptional, and usually the first thing noted is the eruption of vesicles on the trunk, the limbs, or the face. If observed from the very commencement these are at first macules, which in an hour or so become papules, and in a few hours vesicles. Some of the vesicles attain their full size within eight, 12, or at most 24 hours. The vesicles are then usually glistening, hemispherical, or dome-shaped and transparent. On transfixing with a needle the contents escape and the vesicles collapse. The shape of the vesicles is elongated, elliptical, or circular on the trunk and extremities, and irregularly round on the face and the scalp. On the forearms, the hands, the legs, and the feet they are often circular and smaller than those on the trunk. In these latter positions the vesicles, being small, look not unlike the vesicles of modified small-pox, and in addition they have often a more or less shotty feeling. In a large number of cases typical chicken-pox vesicles will be found only on the trunk, not on the face or extremities; as a matter of fact, the distinctive shape and appearance of the vesicles of chicken-pox become less and less characteristic towards the distal ends of the extremities. Often within eight or 13 hours, always within 24 hours, of the appearance of the eruption some of the chicken-pox vesicles have reached their full growth, and are then as large as the vesicles of small-pox in unvaccinated subjects at the fourth or fifth day of the eruption, and as large as, or larger than, the vesicles of small-pox in vaccinated subjects at the end of the third day of the eruption. If the eruption be copious many of the chicken-pox papules abort, many of the vesicles do not attain their full growth, never becoming larger than a small pin's head. In some few cases the vesicles fill only partially with fluid, are flattened, and are of a dull white or tallowy colour; but in these the distribution of the eruption is markedly that of chicken-pox, and the elongated or elliptical shape of many of the vesicles is pronounced. In point of distribution the eruption of chicken-pox is, as a rule, most abundant on the trunk, less so on the face, the scalp, the thighs, and the arms, and still less so on the forearms, the hands, the legs, and the feet. On the palate and the fauces the eruption is present in many cases, but usually it is sparse. Pyrexia in chicken-pox is usually synchronous with the appearance of the eruption, and the temperature may, or may not fall when the eruption is fully out. In cases where the eruption appears in successive crops there is usually a distinct rise in temperature with each crop.

What, then, are the diagnostic points between chicken-pox and small-pox? There are (1) the distribution of the eruption; (2) the shape of the vesicles; (3) the rate of growth of the vesicles; and (4) the unilocular character of the vesicles of chicken-pox compared to the multilocular nature of the vesicles of small-pox.

From what I have just said it will be noted that the distribution of the eruption of chicken-pox is, as a rule, the opposite of that of small-pox. In shape some of the vesicles of chicken-pox are elongated or elliptical; in small-pox the majority of the vesicles are circular. The typical vesicles of chicken-pox attain their full growth in a few hours and are then dome-shaped, distended with fluid, transparent, and they collapse on being transfixd. In small-pox, whether in vaccinated or unvaccinated subjects, the vesicles do not attain their full size on the first day of the eruption, and that is a fact of crucial importance in the differential diagnosis of the two diseases. Observation of the eruption on the face, the arms, and the hands only should never be relied upon for the diagnosis of chicken-pox, for upon those parts the eruption

simulates that of small-pox closely, and very many errors in diagnosis have been made by so limiting the observation. There should be no failure to examine closely the whole eruption.

Though statements are made to the effect that the vesicles of chicken-pox when at their full growth and distended with serum show depressed centres, just like small-pox vesicles, this is not the case. The unruptured chicken-pox vesicles are not depressed in the centre, but the ruptured vesicles may be. The chicken-pox vesicle ruptures naturally or forcibly by scratching or friction, a portion of its contents escapes, and it collapses centrally. In the centre a tiny scab of dried serum forms, occluding the opening and preventing the further escape of serum. It is then that the ruptured vesicle shows a depressed centre, but on close examination a small dried scab in the centre showing that the vesicle has ruptured will be found. This ruptured vesicle may be noted within 12 hours of the appearance of the eruption. I have only once seen an unruptured vesicle of chicken-pox with a depressed centre, and the cause of the depression of that particular vesicle was that in its centre there was a thick long hair—a small mole-hair, in fact—and the epidermis forming the envelope of the vesicle was held down by the hair follicle, thus causing a depression. The vesicle was situated on the abdomen.

Frequent mistakes are made in diagnosing small-pox in unvaccinated children as chicken-pox, such mistakes often resulting in outbreaks of small-pox. If regard be had to the differential diagnostic points that I have endeavoured to emphasise no such mistake should occur.

**Measles.**—Confluent small-pox on the first or the second day of eruption is not infrequently diagnosed as measles, and *vice versa*. The observer is usually misled by the appearance of the eruption on the face, the arms, and the neck. In confluent small-pox the skin in these situations is often intensely hyperæmic, swollen, and studded with raised pink or purple papules, accompanied in many cases by conjunctival suffusion. The patient's aspect and the appearance of the eruption are very like those of measles, but close observation will show that the papules are more raised than are the papules of measles, and by drawing the finger firmly across the forehead the eruption will be felt to be hard and shotty, while in measles, though slightly resistant, it is soft and velvety. That is the diagnostic point. Probably also in small-pox some of the papules will show commencing vesiculation.

**Syphilitic eruptions.**—Usually the scaling and pustular eruptions are mistaken for small-pox. The coexistence of a papular, scaling, and pustular eruption, its symmetrical appearance, and the history of the case should negative small-pox. If the specific eruption be ushered in by very high fever it is to be noted that the papules are not shotty but flat, and careful inquiry and inspection will in most cases resolve the doubt. Here most errors in diagnosis are due to the observer omitting to examine the whole of the eruption and to insufficient inquiry as to the history of the case.

**Herpes.**—Small clusters of herpes, wherever situated, may simulate vesicles of small-pox, but the absence of initial symptoms and full development of vesicles on the first day should obviate any mistake.

**Eczema and impetigo.**—In these conditions also small-pox is negated by the absence of initial symptoms, nor do the vesicles or pustules bear much resemblance to those of small-pox. Yet a considerable number of cases of impetiginous eruptions are diagnosed as small-pox, even in the outpatients' departments of the general hospitals.

**Pemphigus.**—In pemphigus the initial symptoms are absent and the bullæ are larger than small-pox vesicles and are filled with a clear fluid; they collapse on being pricked.

**Urticaria papulosa.**—In this disease the wheals are small, of about the size of a split pea, somewhat hard to touch, and of a dull white colour, and those on the extremities are sometimes not unlike small-pox vesicles. They attain their full size almost at the moment of their appearance, and either have no redness at the base or the usual erythema is present. The initial symptoms of small-pox are absent.

**Acne.**—The initial symptoms of small-pox are absent in acne and the eruption affects the face, the shoulders, and the back for the most part. The pustules are acuminated, sometimes indurated, and they show a central dot. It is well to recollect that the eruption of modified small-pox on the face is sometimes not unlike acne, and it is desirable always to inquire as to the initial symptoms and as to the presence of eruption elsewhere than on the face.

**Rheumatic sudamina.**—In these cases there is the history of rheumatism attended by sweating with the sudden appearance of the eruption, which is most marked usually on the trunk. In the majority of cases the vesicles are small, of about the size of a large pin's head, and that, with the history of the case, is sufficient to exclude a diagnosis of small-pox; but in rare instances the vesicles are large and look not unlike modified small-pox vesicles. I have myself been deceived by an eruption of this character.

**Glanders.**—The initial symptoms in glanders are unlike those of small-pox nor is the onset so sudden. The eruption is sparse, showing as red indurated papules, which rapidly increase till they reach the size of a pea, when they become pustules. There is fetid nasal discharge and the constitutional symptoms are usually severe. The history of the case, the nasal discharge (an exceedingly rare thing in small-pox), and the fact that the severe constitutional symptoms are disproportionate to the amount of eruption, should negative the diagnosis of small-pox.

**Pyæmic skin eruptions.**—Those eruptions which are mistaken for small-pox occur mostly in cases of ulcerative endocarditis. There is usually a comparatively sparse petechial and pustular eruption on the trunk and the extremities. The petechiæ vary in size from that of a lentil to that of a pea, and are irregular in outline. The gradual onset of the symptoms, the date of appearance of the eruption, the great prostration, and the severity of the constitutional symptoms, *qua* the amount of the eruption, should negative small-pox.

The foregoing are the most important but not all the diseases that are mistaken for small-pox, and all those I have mentioned are instances of mistaken diagnosis that passed through my hands in the years during which I was in charge of a small-pox hospital and during the time that it was my duty to diagnose the cases of small-pox before they were sent to the hospital ships.

The difficulties in the diagnosis of small-pox in the eruptive stage are most marked in cases where the eruption is modified by vaccination, especially if there be a very sparse eruption. In small-pox the initial symptoms of headache and backache, rigors, and anorexia and pyrexia are almost invariably present. Indeed, the occurrence of at least some of the initial symptoms is one of the most constant features of small-pox even of the mildest type, and the eruption appears in almost every case after the duration of initial symptoms of about 48 hours. The peculiarity of the eruption of modified small-pox is that its evolution is quicker than is that of the eruption of unmodified small-pox—that is to say, the papules quickly become vesicles and the vesicles soon show signs of pustulation, so that on the second day of the eruption there are definite vesicles which by the third day are in many instances cloudy and opaque. The vesicles are often small and more or less acuminated, frequently not showing depressed centres, and bearing little resemblance, except as regard their circular outline, to the larger, bolder, and clearer vesicles of unmodified small-pox, which show flattened or depressed tops.

It has always appeared to me that many of the mistakes in diagnosis are due to disregard of the significance of the initial symptoms of small-pox. When a patient presents a history somewhat as follows: headache, lumbar pains, anorexia, rigors, and perhaps vomiting and pyrexia, these symptoms lasting about 48 hours, when a papular shotty eruption appears on the face and the extremities, and to a less extent on the trunk, the temperature falling on, or shortly after, the appearance of the eruption,—such a case is in all probability one of small-pox; but if a papular, vesicular, or pustular eruption appears on a person, and the initial symptoms just mentioned have been absent, then most probably such a case is not small-pox.

In the diagnosis of small-pox the following rules should be observed. 1. It should never be forgotten that the initial symptoms of small-pox are most constant both in vaccinated and unvaccinated subjects. 2. When called to a case the practitioner should never take for granted that the eruption on the trunk is like the eruption on the face and extremities, but in every case he should examine the whole eruption. Disregard of this precaution leads to many mistakes. 3. It should not be assumed that because a case of small-pox has occurred in a house, therefore a vesicular eruption appearing on another inmate of the same house about the same time is small-pox. I have known cases of chicken-pox and small-pox occurring simultaneously in the same house, and small-pox and enteric fever cases in the same family at the same

time. 4. It should be remembered that in a very large number of vaccinated subjects small-pox is so mild that as soon as the eruption—consisting sometimes of not more than half-a-dozen spots—has appeared the patient feels well. 5. Care should be taken to avoid ascribing the spots on the face in a mild case to digestive disturbances and sending the patient to the seaside for a little change of air. This may not be the custom, but it is done. A very remarkable instance of mis-diagnosis of this character came under my notice many years ago. The housekeeper of a gentleman in the suburbs was admitted under my care suffering from black small-pox, from which she died. She had ridden in omnibuses and trams to a general hospital in the south of London, was admitted there, and was sent to me on the following day. I learned from her that her master had been ailing a little time before and had been sent to the Isle of Wight for a week's change of air. I saw him some days after his return. He had had a mild attack of small-pox, the spots being ascribed to some digestive disturbance. I asked him to show me his feet, and under the thick skin of the sole of one foot I found an unruptured small-pox pustule.

General practitioners may be assured that they are not the only members of the profession who make mistakes in the diagnosis of small-pox; the physicians of general hospitals are mortal and err in this way, and even the small-pox experts with their special knowledge of the subject are sometimes puzzled and deem it advisable to keep cases under observation till time and the course of the disease resolve the doubt.

Mistakes in diagnosis are more frequent proportionately in times when small-pox is not prevalent. For instance, during the years 1898, 1899, and 1900 176 cases in London were certified to be those of small-pox. Of these 98 were correctly and 78 incorrectly diagnosed. Why, it may be asked, do mistakes so frequently occur in the diagnosis of this disease? The answer is that small-pox is now so erratic and uncertain in its occurrence that many of the younger members of the profession have had little or no opportunity of observing it so as to familiarise themselves with its diagnosis. The result is that only a few men having special knowledge and experience of small-pox are to be found in London, and these are mostly in the service of the Metropolitan Asylums Board. Surely it is most desirable that in view of the great interests involved facilities should be afforded to the profession for obtaining an expert's opinion in cases of doubtful diagnosis. I would venture to suggest that the Metropolitan Asylums Board should appoint a small-pox consultant whose opinion in cases of doubtful or difficult diagnosis should be at the service of the general practitioner and of hospital and infirmary physicians. In this way many cases of small-pox that are mis-diagnosed as chicken-pox, measles, and other diseases might be correctly diagnosed and the untoward results of a mis-diagnosis be avoided, while the incorrect diagnosis of small-pox in many cases of chicken-pox, measles, and other diseases might be obviated, whereby the patients would be saved much inconvenience and the physicians much worry.

Another point of the utmost importance arises in connexion with the diagnosis of small-pox. It is this: In what way can the present prevalence of small-pox be best utilised for the purposes of medical education? An opportunity is now presented to the hospital authority entrusted with the clinical teaching of infectious diseases in London, for the clinical demonstration of small-pox to the senior medical students, medical officers of health, and general practitioners. All patients certified to be suffering from small-pox are removed at present to the Metropolitan Asylums Board's wharf at Rotherhithe. They are detained there a short time and are then transferred to the hospital ships. There is, therefore, at the wharf ample material ready for demonstration and the patients are for the most part in the early stages of the disease, when the eruption is particularly suited for the demonstration of the diagnostic points of small-pox. In addition, much may be learned from the cases of mis-diagnosis sent there. Some facilities have been afforded by the Metropolitan Asylums Board to medical officers of health for seeing small-pox at the wharf and at the hospital ships. The systematic clinical teaching of small-pox, however, has not yet been undertaken, although there appears to be no sufficient reason for delay. I feel sure that the Metropolitan Asylums Board will recognise its responsibility and its duty in this matter and that it will speedily utilise to the fullest extent the small-pox material at its disposal at the wharf and at the hospital ships for the clinical demonstration of that disease to students and practitioners.

Shooters Hill, Kent.

### THREE CASES OF EARLY INFANTILE TABES DUE TO CONGENITAL SYPHILIS AND HEREDITARY NEUROSIS.

By G. T. BROOKSBANK JAMES, F.R.C.S. ENG.,  
ASSISTANT SURGEON TO THE ROYAL EYE HOSPITAL, SOUTHWARK.

THESE cases, which are of exceptional interest from their rarity, have been recently under my care at the Royal Eye Hospital.

CASE 1.—A young woman, aged 20 years, attended my outpatient department early in November, 1901, accompanied by her mother; she complained that everything she looked at appeared to be double and that she had been troubled by this for about a week. She was employed as a general servant at a house some 20 minutes' walk from her own home, where she attended every morning at 7.15, and was employed until 4 P.M., with two short intervals for meals. She stood a good deal while at work. She was an intelligent girl of moderate height and was well made. The upper lids were slightly retracted, the left more so than the right, and when she glanced down they lagged perceptibly behind the movements of the eyeballs. The pupils were unequal, the right being the larger; they were quite inactive to light but reacted slightly on accommodation. There was complete paralysis of the left external rectus. This was the only external ocular muscle affected. Vision in the right eye was  $\frac{3}{4}$  and in the left eye  $\frac{3}{8}$ , the defect in the latter being probably due to the want of accurate fixation. The cornea, iris, lens, and fundus on each side were healthy. The thyroid body was slightly and uniformly enlarged, the heart was regular, 80 in frequency, and there was no bruit over the precordial area or the neck. When the patient was made to stand with the feet together and the eyes closed she swayed perceptibly; the knee-jerks were completely absent and there was general slight but definite anaesthesia over the lower extremities. There were no indications of old periostitis or other bone affection. The head was fairly well shaped and the bridge of the nose was not depressed. The teeth were not good, several molars being decayed. The upper central incisors were widely separated and were narrowed below at their cutting edges. There were no scars at the angles of the mouth, on the palate, or on the fauces. With regard to her previous history, she was a full-term child nursed for 18 months; there was no history of snuffling or rash on any part of the body. Her general health had been good until the present illness, and she had never been under medical treatment. On close inquiry she owned to not having felt well for about 12 months. She became readily tired on walking and had lost flesh; for about a month she had complained occasionally of darting pains in the upper dorsal region, but no girdle sensation. Quite recently she had been troubled with sharp shooting pains in the course of the ulnar nerve in the right forearm, with numbness in the ring finger and little finger of the right hand. She had also felt a few sharp twinges in the calf of the left leg. Her mental condition appeared to be normal, though she owned to recent slight forgetfulness. There was no tremor. Seeing that the case was in all probability one of the rare examples of infantile tabes I examined the other members of the family. The father, aged 46 years, was a strong healthy man. He had been married 25 years; he was well until four years ago, when he had an attack of rheumatic fever. He had occasionally suffered from sore throat at rare intervals and for short periods; there were no physical evidences of past mischief with the exception of a scar in the groin. On careful inquiry he described an illness when 19 years old for which he was in hospital for about 10 days. He had a discharge from the urethra and a suppurating bubo in the right groin, but no sore on the penis, sore throat, or rash. He was under treatment with pills and ointment for about six weeks. He subsequently got quite well and had no further trouble. His father died from sunstroke, aged 47 years; his mother died from diphtheria, aged 46 years; and one brother and one sister died from phthisis. The mother, aged 42 years, was a delicate-looking woman; there was a history of congestion of the lungs four years ago. She had had attacks of sick headache every six weeks and was obliged to stay in bed when affected by them. There were no history or physical signs of present or past specific mischief. As to the family history, there was a sister;

aged 38 years, who was married and had two children, and who was in good health. There was a brother who died at the age of four years who had harelip and cleft palate. There was a brother, aged 35 years, who had recently been in the lunacy ward of the infirmary with acute mania following influenza; he had been ill for two months, but had now recovered and had resumed his occupation. There was a sister, aged 30 years, married, who had three children and who was well. There was also a brother, aged 27 years, married, who had three children and who was well. Three children had died in infancy; the cause was unknown. Her father was living, aged 68 years, and her mother died from small-pox, aged 46 years.

The following are notes upon the remaining children of this couple.

CASE 2.—A boy, aged 17 years, of good height and fair development, with a square head, a prominent forehead, and a saddle-shaped nose. The upper central incisors were separated and pegged. There were scars at the angles of the mouth. There were gross central choroido-retinal changes in the right eye, with vitreous opacities. R.V. =  $\frac{1}{2}$ ; L.V. =  $\frac{1}{4}$ . The right pupil was sluggish to direct light but was active consensually. The knee-jerks were sluggish; there was no anaesthesia or incoördination, and there were no mental symptoms. He was a full-term child, nursed for 18 months. He had had snuffles. He had had no rash and no medical treatment during the first three years. There was a history of eruption of the head when he was three years old lasting three months, and he had been treated for this. His milk teeth were said to have been good. Visual acuity in the right eye began to fail three years ago. He had attended the Royal Eye Hospital and was at present under treatment. This patient was under the care of Dr. W. J. Collins who has kindly allowed me to refer to his case.

CASE 3.—A girl, aged 15 years. She was of good height, was well made, and intelligent. Her complexion was fairly good; her nose was saddle-shaped. Her central incisors were separated and narrowed. There were no scars at the angles of the mouth. The pupils were unequal, the right being the larger; they were very feebly active to light and reacted to accommodation. The knee-jerks were sluggish. There was no anaesthesia or incoördination. Vision =  $\frac{1}{2}$  each eye; the cornea, fundi, &c., were normal. She was a full-term child, nursed for 18 months; there was no history of snuffles or of rash; the upper extremities were paralysed during infancy, and the patient underwent medical treatment for this at the Belgrave Hospital. The thyroid gland was normal. A systolic murmur was heard over the apex of the heart. There was a history of rheumatic fever and influenza, but no other illness.

CASE 4.—A girl, aged 10 years. She was well made, of good height, and intelligent. Her complexion was fairly good. Her nose was saddle-shaped. The central incisors were separated and narrowed. There were no scars at the angles of the mouth. The pupils were normal. The knee-jerks were present. She was a full-term child, nursed for 18 months; there was no history of snuffles or of rash.

CASE 5.—A girl, aged eight years. She was intelligent. Her skin was thick and rather pasty-looking. She had a saddle-shaped nose. The central incisors were separated and narrowed below. The pupils were unequal, the right being the larger; they were inactive to light and feebly inactive to accommodation. The knee-jerks were sluggish. The fundi were normal. Right vision =  $\frac{1}{2}$ ; left vision =  $\frac{1}{4}$ . There was some compound hypermetropic astigmatism. There was no history of pains and no anaesthesia or incoördination. She was a full-term child, nursed for 18 months. There was no history of rash or of snuffles.

CASE 6.—A boy, aged four years. He was a full-term child, nursed for 12 months. There was no history of illness and no abnormality.

CASE 7.—A healthy infant, aged 18 months.

Case 1 is evidently an example of tabes, and though it is of course impossible to say if mental symptoms will supervene and the case end as one of general paralysis at present it appears to be uncomplicated. The existence of two of the symptoms of early exophthalmic goitre at the same time is probably accidental, though the retraction of the upper lid is more likely due to some central irritation than to an affection of the sympathetic. Case 3 shows the pupillary phenomena connected with tabes and sluggish knee-jerks. Case 5, with sluggish knee-jerk and the Argyll-Robertson pupil, may also fairly, I think, be described as a case of early tabes.

Such cases as these must be very uncommon. Mr. Jonathan Hutchinson's immense experience has not provided him with a single example of locomotor ataxy due to congenital syphilis nor has he seen from the same cause the isolated paralysis of an external ocular muscle such as that of the left external rectus in Case 1. Raymond has not seen a congenital example among 500 cases of ataxy.<sup>1</sup> Sir William Gowers has seen several cases.<sup>2</sup> Dr. F. W. Mott has described one case. The characteristics distinguishing such cases from Friedreich's ataxy have recently been specially pointed out by Mackie White<sup>3</sup> and others. The presence of the Argyll-Robertson pupil and a history of syphilis are the chief points of distinction. Syphilis is, of course, the primary etiological factor in the examples I have described, and though hereditary neuropathy on the mother's side may have had some weight in determining the tissue incidence of the disease, who would assign to it such power in the absence of syphilis? None of the more indirect and exciting causes dwelt on by Dr. T. S. Clouston, Dr. Mott,<sup>4</sup> and other observers seem to have been present in the cases I record. Case 5, which shows some undoubted evidences of tabes at the early age of eight years, the earliest age, if I remember rightly, at which infantile general paralysis has as yet been met with, can scarcely be considered as influenced by the crisis of puberty. Indeed, on careful inquiry, I can find no evidence that these children have led other than a fairly healthy life in a comfortable home and with kind parents. They are uniformly intelligent and well-behaved, nor is there a history of physical over-exertion save in the instance of Case 1. These cases are evidently by no means so common as the examples of infantile general paralysis. I am, however, inclined to think that if careful examination of the pupils and nervous system were undertaken in more cases of congenital syphilis that we should find Argyll-Robertson pupils and absent knee-jerks more frequently than is usually supposed. At any rate, the knee-jerks were absent in two cases of interstitial keratitis which came recently under my own observation. Whether the Argyll-Robertson pupil and the absent knee-jerk can remain through a long life the sole evidences of the influence of congenital syphilis on the nervous system I do not know, but the occurrence of such cases lends strength to the hypothesis that possibly some of the small percentage of cases of adult tabes in which acquired syphilis as a factor can be definitely excluded may be due to a faint congenital taint, so faint, indeed, that the patient may not disclose it by any of the other evidences on which we are accustomed to rely. It must also be remembered that an examination of the collateral relatives (so frequently an aid to diagnosis) is a much more difficult matter to obtain in the case of adults affected with congenital syphilis than it is in the case of children. A glance through a family history such as this brings vividly before the mind the subtle influence of this terrible disease. In presence of the serene apathy of the public and legislature with regard to this great question we may well consider whether even with the limited means that medicine has placed in our hands we do everything that is possible to prevent such sequelæ in the congenital form of the disease. Infants who suffer in the first year of life are taken to the various children's hospitals. They are kept under treatment for varying periods, which seldom exceed a year. They are then frequently lost sight of. Succeeding children in the same family are only taken to a hospital if the snuffling is severe enough to prevent them suckling or the rash and wasting sufficiently obvious to alarm the mother. Marked and perhaps moderate cases of infantile syphilis are thus no doubt generally treated, but a large number of cases where the malady is partially latent in the early stage receive no attention until towards puberty or later, when an attack of interstitial keratitis, choroiditis, or disease of bone draws notice to the congenital malady and energetic and long-continued mercurial treatment is often adopted with but partial success. I speak in this matter from a knowledge of the early history of many cases of interstitial keratitis. It is remarkable how frequently one meets with no record of symptoms in infancy. Mild symptoms are generally present, no doubt, as we so frequently meet with the relics of past inflammatory

<sup>4</sup> *Archives of Neurology*, 1899.

trouble in patients towards the age of puberty who give no history of early illness or treatment. The important fact remains, however, that such early symptoms were not of sufficient severity to induce the parents to bring their children for treatment. Moreover, such treatment is often very short and is discontinued with the disappearance of the rash. Only one of the children whose cases I have described in this paper were under treatment in infancy. Not one of the 25 cases of infantile general paralysis described by Dr. Mott were under treatment in infancy, though their disease was proved to be due in nearly every instance to syphilitic inheritance. These facts are surely of importance. They suggest that our present methods of treating congenital syphilis leave much to be desired. They suggest that such methods are more fitted to disperse a rash or to control a symptom than to ensure the perpetual latency of a disease which we cannot cure. The infection in many of these latent cases is derived from the father nor can we hold dogmatically that its virulence decreases in power with successive children, if we compare Case 1 with Case 5. To place the mother under treatment in a good many cases would be useless. Something might be done by the treatment of the father, but more, possibly, by the systematic early and long-continued treatment of the children. It would surely be wise to warn all parents who have been obliged to take one child for treatment in the early stage that all their subsequent children should be considered as infected and should be brought for inspection, to undergo a prolonged course of treatment if they show the slightest symptoms of the disease. Few surgeons will deny the efficacy of mercurials in bad cases of infantile syphilis in the first year of life. Most surgeons employ them in those later manifestations which are analogous to tertiary syphilis in the adult. It is surely more rational to consider the disease as present at birth in all infected families and to put the successive children at once under supervision, using mercury and the iodides at occasional intervals for many years—not to treat a symptom, but to prevent its manifestation in the manner suggested by Sir William Gowers in acquired syphilis. No doubt it would be rash to anticipate that in this way a great diminution in the number of patients suffering from the later affections would be brought about, but if we could in some greater degree prevent the occurrence of those sad cases where blindness, deafness, or paralysis are the heralds of manhood we should not have laboured in vain.

The following is a complete list of the children born to this couple arranged according to age. I have personally examined every living member of the family save one. There have been no miscarriages. 1. A boy, born seven and a half months. There was no history of rash or of snuffles. He had water on the brain and died when seven months old; he was nursed. 2. A girl, born 15 months after the first child; she was a seven and a half months' child and was nursed for 18 months. There was no history of rash, snuffles, or early treatment. When 12 years old she attended the Orthopaedic Hospital for crooked spine. She is now married and has two children. 3. A boy, born 14 months after the second child; he was an eight months' child and was nursed for five weeks. There was no history of rash or snuffles and no treatment. He died from bronchitis when five weeks old. 4. A girl, the first patient whose case I have recorded. She was born 14 months after the third child. 5. A girl, born 13 months after the fourth child at full term; she was nursed for 18 months. There was no rash or snuffles and no early treatment; she died after a week's illness when three years old. 6. A boy, born two years after the fifth child at full term. He had snuffles very badly from birth and difficulty in the suckling, but no rash. He was treated for two weeks and died when seven weeks old. There was no wasting. 7. The boy with "central choroidoretinitis" described as Case 2 in the preceding notes. 8. The girl, aged 15 years, with inactive pupils, described in the preceding notes. 9. A boy, born two years after the eighth child at full term. He was nursed for 18 months. There was no rash or snuffles and no treatment. He was healthy until the age of two years and 10 months, when he died from whooping-cough and bronchitis. 10. The girl, aged 10 years, healthy as regards the nervous system, &c., described in the preceding notes. 11. The girl, aged eight years, with inactive pupils and absent knee-jerks, described in the preceding notes. 12. A boy, one year and nine months, born at full term. He was nursed for one month. There was no rash or snuffles. He wasted and died, aged six

months; he was under treatment for one week. 13. The boy, aged four years, referred to in the preceding notes. 14. The baby, aged 18 months, referred to in the preceding notes.

Carlisle Mansions, S.W.

## SOME POINTS IN THE PROGNOSIS OF MENTAL DISTURBANCE.<sup>1</sup>

By W. J. HANDFIELD HASLETT, M.R.C.S. ENG.,  
L.R.C.P. LOND.,

MEDICAL SUPERINTENDENT AND LICENSEE, HALLIFORD HOUSE.

I PROPOSE to give you some general points affecting the prognosis of attacks of mental disturbance and I trust it is a subject which may prove of some little interest to the members of this society. I am sure that there is no one present who has not been called upon to treat cases of brain instability either in the home of the patient, in the house of a medical man, or in a public institution, such as an infirmary or a hospital, where these cases are often at any rate temporarily treated. It is not proposed to give any detailed classification of mental diseases or to deal with those very rare forms of insanity not usually seen in general practice. It is simply my intention to give you some broad lines on which to form a prognosis, based upon my notes of some 200 cases which have occurred in my own practice.

Of all the ills to which we medical men are called upon to minister the mind diseased requires most care, caution, and judgment in the formation of a prognosis, and I consider that a judicious hedging is often not only justifiable but necessary. Some of the questions which the anxious relatives will ask you are as follows: Will the patient die? Will he recover? How long will the recovery take? What is the danger of recurrence? and each of these will have a very big note of interrogation after it. There are other more remote and less urgent questions, such as whether the patient should marry when he is convalescent, whether he should be relieved of the control of his monetary affairs, and as to his testamentary capacity. These questions are largely medico-legal and hardly come within the scope of this short paper.

The majority of the cases with which you will be asked to deal will probably prove to be suffering from mania or melancholia, because nearly all chronic forms of insanity begin with one or other of these emotional conditions and because they are more obvious and compel the attention of the friends sooner than cases of, say, failing memory, defective judgment, or harmless delusions. Mania *per se* is a very curable disease, whether it be simple mania, characterised by insomnia, constant rambling speech, and motor excitement, or the severer form of acute mania with all those symptoms accentuated and with complete incoherence and the presence of sensory hallucinations and numerous delusions.

In all probability the case which appears worst to the friends is the one in which the prognosis is most favourable, for the patient in whose case there has been a sudden severe onset with violent excitement, raving speech, and subconsciousness to surroundings is much more likely to recover than one in whose case there have been obscure indefinite beginnings and a prolonged insidious course. Putting it broadly, when the onset is sudden and can be traced to a definite cause, when the patient is under 35 years of age and otherwise healthy, and when he has not had previous attacks, the prognosis is good. The possession of a neurotic or insane ancestry does not militate against his recovery, although it will predispose to future relapse. Therefore inquire carefully into the cause and history: if both are well defined the prognosis is good. Above all, eliminate general paralysis of the insane, tabes, tumours, epilepsy, and other brain diseases, because these are often masked by mania, particularly the first and the last. If the patient's general health be poor, if he has lost weight and is anæmic and sleepless, it brightens the prognosis, because as we improve his physical condition his brain will clear *pari passu*. The chances are that one condition is intimately associated with the other. If the patient be in robust health from the start or if his brain does not clear up as his bodily

<sup>1</sup> A paper read before the Windsor and District Medical Society on Nov. 20th, 1901.

health improves the prognosis is less favourable. Again, if you find your patient harping on the same delusion or delusions week after week you will feel anxious about him because that delusion will tend to become fixed and crystallised in his brain and will persist. When the delusions are very numerous and kaleidoscopic and change their character frequently we may feel more hopeful of their ultimate disappearance. The nature of the delusions matters little in acute mania. Their changeability or fixity is the point which interests us most.

With regard to hallucinations, those of sight have the least grave significance. Auditory hallucinations generally pass away as the acute symptoms subside, but if they persist for over a year, particularly if they be associated with delusions of persecution, the condition is likely to become chronic. Hallucinations of taste and smell are extremely grave and seem to indicate permanent brain injury. I have never known a case in which they were present to recover. They are frequently seen late in a series of attacks of alcoholic mania. Periodicity is another characteristic which must make us pause in our prognosis. Periodicity must not be confused with recurrence. The latter occurs at irregular intervals and can generally be traced to a cause. The interval may be weeks or years and the attacks point to unstable mental equilibrium, but not to the establishment of a "habit." Periodicity means that the interval between the attacks is always of the same length. The return of the alienation may be coincident with menstruation or the seasons of the year, or it may have no such relationship, but in any case a cycle is formed with fairly regular intervals between the attacks. When this cycle is established it is called by the French "*folie circulaire*," and it is considered to be quite incurable. The mania ushering in fevers or appearing at the climax is usually favourable, but the insanity following typhoid fever, which is due to great exhaustion, I have found to be very unfavourable. It does not kill, but in four cases out of my six chronic delusional insanity supervened.

I must touch on two or three very common varieties of mania before I leave this subject.

**Acute delirious mania.**—This is a disease which requires prompt treatment in order to save the life of the patient. It is characterised by complete incoherence, low muttering delirium, pitting of bedclothes, great tissue waste, and often increased temperature and grave constitutional symptoms. Large quantities of fluid, easily digested food with stimulants, and probably hypnotics, must be given by the nasal or the oesophageal tube, otherwise the patient will rapidly sink. The following are some of the points for and against recovery. If food can be given in large quantities and digested, if sleep can be procured, if the pulse remains below 100, if the increase of temperature is slight, if the tongue remains moist, and if there is no muscular tremor or subsultus tendinum the prognosis is good. If food cannot be retained in sufficient quantities (rectal feeding is no good), if the pulse is rapid, and if the temperature be over 100, and particularly if typhoid symptoms appear, such as dry, brown tongue and sordes, the prognosis is bad. Out of eight cases of this malady six recovered and two died. Of the latter, one could retain no food, however prepared or administered, and in the other a persistent temperature of 102° F. burnt out the patient. Both the vomiting and the fever were of neurotic origin and no visceral lesion was found either ante mortem or post mortem.

**Puerperal mania.**—This is very common and is perhaps the most curable variety of mental disorder. When it occurs after post-partum or ante-partum hæmorrhage it is often fatal, but on an average from 80 per cent. to 35 per cent. of the total number of cases make good recoveries. Out of my 14 cases 13 recovered and one remained in a state of chronic mania. Heredity does not affect the prognosis, but delay in treatment and age influence the recovery rate. No class of case requires more immediate attention, and every week which is lost affects the chances of recovery. If the patient be over 35 years of age and the type is more melancholic than maniacal the prognosis is not so good. In any case recovery will be delayed. Half of the recoveries take place before the expiration of six months and 90 per cent. during the first year; after that the prognosis is not good.

**The insanity of adolescence.**—This, particularly in girls, is another type of insanity from which recovery is common. It has a peculiar disposition to relapse, for which we must prepare the friends of the patient. When a young man

or a young woman quickly recovers from an acute attack and is apparently well we must warn the friends that the brain is not yet stable and that probably other attacks will follow before permanent convalescence is reached. On the other hand, when they are inclined to be despondent through the recrudescence of maniacal symptoms we may hearten them by telling them that this is not unusual and does not in itself lessen the chances of recovery. The male adolescent does not do so well as the female. The prognosis remains good longer in the case of a woman. Half of the recoveries take place before the fifth month in the male, after which only a small proportion recover; in the female the prognosis is good up to 10 months. The female is more purely maniacal; the male is often melancholic with erotic and pseudo-religious ideas and practises masturbation. Out of 10 cases—six male and four female—three men recovered and all the women.

**Melancholies.**—In the great class of melancholics youth, a definite cause, a definite onset, and early treatment all influence recovery, as in mania. The mental reductions do not reach the same low level as in mania, and as a consequence the prognosis is hopeful over a longer period. A patient under my own care made a perfect recovery after six years of severe melancholia, and cases of even longer convalescence are well known. Sudden recovery is unusual and seldom permanent. The majority of the cases which recover do so in the first 12 months, and of those which remain unimproved over that period only 5 per cent. or 6 per cent. make ultimate recoveries.

The principal *pros* and *cons* of prognosis are as follows. As the disease is not so acute hallucinations are more serious, especially those of hearing. Imperfect bodily nutrition, such as loss of weight and trophic changes in hair and skin, the latter becoming earthy and greasy in appearance, are of ill omen. Degeneration of habits and inattention to the calls of nature, a constant desire to pick and rub the skin and pull out the hair are also of unfavourable augury. Certain delusions seem more liable to become fixed and permanent than others. For instance, visceral misinterpretations, such as the belief that the bowels never move properly, that the food does not enter the stomach, or that foreign substances are fixed in the body and require a surgical operation for removal, also delusions of persecution, plots, or unseen agency do not readily pass away. Again, sexual delusions, such as those respecting impotence, are of grave significance, and masturbation or fits are serious complications. The prognosis in climacteric melancholia is rendered very unfavourable by secret indulgence in alcohol or drugs and I have noticed that the growth of facial hair in women has always been an indication that recovery will not take place. Prolonged suicidal promptings are of unfavourable import and we must be on our guard in this respect because the tendency often remains dormant for months only to reappear when least expected. Adipose tissue and melancholia seem to be almost incompatible and an extra layer of fat is a very effective armour against a return of depression. Hence in treatment we do all that we can to encourage increased weight. An interest in her personal appearance is one of the primitive instincts of woman, and when we see her natural vanity re-awakening we begin to feel very hopeful. Some psychologist said that "a woman is no better than her hair," and quite recently I had a very good example of this. A young woman who had been suffering from a severe mental breakdown of nearly a year's duration suddenly became shocked to find that her hair which before her illness was of a golden hue had now returned to its natural somewhat unattractive colour. She demanded a bottle of her favourite preparation and set to work on her locks; from that day she made steady improvement and now both her hair and the brain beneath it are restored to their former brilliancy.

Although by far the largest number of the insane must be classified as suffering from dementia yet that subject requires scant attention in a paper on prognosis by reason of its incurability. The recognition of dementia is rarely difficult, so that with an easy diagnosis and a definite prognosis the duty of the medical man is, if unpleasant, far from difficult. He may, however, be asked to give an opinion as to the probable duration of life and then he must consider the primary cause of the dementia as well as the general health of the patient. When the mental enfeeblement follows an acute brain-storm such as mania or melancholia it leaves the mind crippled and damaged and incapable of performing all the higher functions of intellectual life. The judgment, the memory, and the

reasoning power are all impaired, the faculty for origination and continuous application is gone, the tastes and habits are reduced to a lower level, self-control is weakened or is replaced by impulsiveness, and the higher instincts, such as affection for family and friends, are impaired or abolished. In fact, the fine edge is taken off the patient's character and all that this means may be summed up as weakened inhibitory power. After all, mental inhibition is artificially built up by years of training and education, we are not born with it. It is the highest faculty of the mind—and it is the highest faculties which suffer first in severe mental disorders. The patient is negligent in his dress, careless in his manners and speech, self-engrossed and indifferent to the feelings of others; the light of intelligence has faded from his countenance, which is now dull and vacuous. This is by no means an extreme picture. Much deeper reductions occur and the unfortunate patient may be reduced to a level little removed from that of the animal world. All this time he may grow stout and strong, he may eat greedily, he may sleep well, and he may not be unhappy. Certain automatic habits remain to him. He can walk and he can engage in simple employment or in childish amusements. Shielded by his crippled brain from the violent emotions, the hopes, the fears, the disappointments, the ambitions of human life, he pursues the even tenour of his way. Granting that he is properly cared for and other things being equal he possesses a better chance of longevity than his sane contemporaries.

Far otherwise is it with the patient whose dementia is due to organic causes—the general paralytic, the hemiplegic, the epileptic. The decadence of the general paralytic is steady although the duration of the disease is uncertain. During its second stage most patients suffer from cerebral seizures of one form or another and the apparent effect is usually very slight and transient. They are either "syncopal attacks," epileptiform or apoplectiform fits, *petit mal*, or some variety of hemiplegia or monoplegia. The effect of these I would describe in the following way. If you can picture the general paralytic going steadily down a long flight of stairs to the finish, when he has one of these attacks he jumps several steps and starts from a lower plane on his downward progress. As far as my experience goes you will be perfectly justified in stating that the duration of life will be dependent upon the frequency of these congestive seizures.

No rule can be laid down as to when dementia will supervene in epilepsy. That it does occur in a greater or less degree in every case is indisputable. You are all cognisant of the injurious effect of epileptic discharges during the developmental stage of the brain and we are all familiar with the abnormal mental conditions of epileptic children. In giving an opinion as to whether mental symptoms, such as defective moral sense, irritability, impulsiveness, and the evidences of dementia enumerated above, are likely to result from epilepsy, you will take into consideration the age at which the fits began, their duration, and their frequency. Fits commencing during the first five years of life very frequently leave mental defect. It is less likely, but still probable during the second five years. The character of the fits does not seem to matter much, although Dr. J. Hughlings Jackson thinks that *petit mal* is more potent for evil, as occurring in a higher mental substratum. There is no doubt that the frequency of the fits is very powerful in producing deterioration. Yet when all is said we cannot shut our eyes to the fact that one patient may have thousands of fits spread over many years and still show very slight deterioration of mental power, while another may rapidly degenerate under the influence of a short course of fits. The inherent constitution of the brain and its greater or lesser resistive power to the damaging effect of frequent discharges from the cortical cells must be reckoned with. This, however, is usually an unknown quantity.

Time permits me to refer in the most cursory manner only to the insanities caused by syphilis, alcoholism, and senility. Syphilitic insanity may appear 20 years or more after the primary inoculation, and there are probably no other manifestations of the poison. It is not due primarily to changes in the nerve substance but in the vascular and fibrous tissues of the brain; endarteritis is usual with narrowed lumen, and the brain, particularly the white matter, becomes starved of blood. Loss of memory, change of character, tendency to lying, thieving, and immorality are common, and fits often occur. The condition is quite incurable, but it does not tend to shorten life. The prognosis in the various forms of insanity caused by alcohol is good if the poison can be cut

off, but, as we all know, it is a very large "if," indeed, which confronts us. Alcoholic delusions, mania *à potu*, and the early stages of chronic mania are all curable by abstinence, but alcoholic dementia is incurable nor is the patient likely to be long-lived, as the indulgence which damaged his brain has in nine cases out of 10 laid the seeds of other grave visceral disease. Senile mania or melancholia, characterised by amnesia, irritability, great nocturnal restlessness, with selfish, suspicious, and noisy behaviour, is not always incurable. A considerable number of patients make a fair recovery, a great many die, and others pass into dotage with brain-softening.

Before I conclude I wish to lay stress upon one important point and perhaps it will receive emphasis by being the last paragraph in my paper. Never readily condemn a patient as suffering from dementia after an acute mental attack. There is a period of exhaustion and reaction after a brain-storm and the patient is stuporous and restless. He cannot employ himself. He is careless, perhaps dirty, in his habits, his volition is weak, and he has no self-confidence. The condition is very like true dementia, but the cloud will pass, the paralysed energies will revive, and a good recovery will ensue. This condition has deceived me—let it not deceive you—into making a prematurely gloomy prognosis.

Sunbury-on-Thames.

## TUBERCULOSIS OF THE HEART.<sup>1</sup>

By H. NEWTON HEINEMAN, M.D.

OMITTING the common form of tuberculosis of the pericardium, which extends from chronic tuberculous pleurisy by contiguity, I purpose to consider tuberculosis of the endocardium, of the myocardium, and of the pericardium.

### TUBERCULOSIS IN GENERAL.

Tuberculosis of the heart has been considered as of the rarest possible occurrence until Weigert<sup>2</sup> fixed attention upon the fact that, according to his experience at all events, in the majority of cases of acute general miliary tuberculosis discrete small tubercles would be found in different portions of the heart. The heart should more commonly have been found to be the seat of tuberculous ulceration, since Weigert, in 1877, gave to the medical profession the famous clue by which general tuberculosis (general infection) became possible, and is probably caused, pointing out the fact that tuberculous ulceration of the pulmonary vessels existed in some of these cases and that in others tuberculous ulceration of the thoracic duct (Ponfick's<sup>3</sup> discovery) was found and was the probable avenue of general infection. The present more perfect staining methods (which we owe in part to Weigert) will certainly furnish us with a greater number of cases of tuberculosis of the heart in the future.

The idea of infection of the pericardium from the mediastinal and the smaller or larger bronchial glands, themselves previously degenerated, cheesy, and tuberculous, is the result of Zenker's<sup>4</sup> researches. This infection is transmission by contiguity. So far as the mode of the infection goes there is no reason to suppose that it is different from that in which the tubercle bacilli do their work in other parts of the body. Thus Wechsberg<sup>5</sup> sums up his work in the following sentences: "1. Tubercle bacilli destroy by their poisonous action the cellular and interstitial tissue round about them. 2. They injure the newly-formed cells only to the extent that the connective tissue and vascular formation is interfered with and that the protoplasm of these tissues is only partially destroyed (giant cells, spindle cells). 3. Finally, the newly-formed cells themselves are completely destroyed (cheesy degeneration)."

### TUBERCULOSIS OF THE ENDOCARDIUM.

Tuberculous endocarditis was met with by Corvisart, Wagner, Potain,<sup>6</sup> Rindfleisch,<sup>7</sup> Lancereaux,<sup>8</sup> Letulle,<sup>9</sup> more

completely described by Perroud,<sup>10</sup> and latterly more exactly by Kundrat,<sup>11</sup> Cornil,<sup>12</sup> Heller,<sup>13</sup> and Weigert.<sup>14</sup> Tuberculous endocarditis has been almost exclusively observed in cases of acute general miliary tuberculosis. Usually it gives no physical signs during life, because the rapid progress of the disease gives no opportunity for their development. At the necropsy two forms are met with: first, that of granules or nodules; and secondly, that of cheesy masses. The latter form is the less frequent. Letulle met with the latter form once. Near the septum of the left ventricle he found two masses, hard and yellowish-green, one on the upper border of the left ventricular wall and the other on the summit of a papillary muscle of the mitral valve. Perroud found the nodular form quite common in children who had died from acute miliary tuberculosis and especially of tuberculous meningitis. The mitral valve is the favourite and almost exclusive seat of this form of endocarditis. On the border of the auricular surface of the two valves, a few millimetres' distance from the attachment of the tendinous chords, we find vegetations which are formed of minute nodules and may be discrete or confluent. The tubercle bacilli are usually found in the superficial layers. It must, however, be borne in mind that not all endocarditic nodules in tuberculous cases are tuberculous. As to the manner of infection, the mode of transmission already referred to deserves a brief repetition here.

Although Mugge first described a case of tuberculosis of the pulmonary artery and vein in a case of acute general miliary tuberculosis it was Weigert's work, already referred to, that cleared up the mystery of the path of infection. In 12 fatal cases of acute general tuberculosis he found 10 instances of tuberculosis of the pulmonary vessels and two of tuberculosis of the thoracic duct. In the pulmonary veins the disease appears in the form of thrombi or polypoid vegetations. These vegetations occupy the entire thickness of the wall of the vessel and take origin in a caseous centre without. Weigert considers these vegetations the starting-point of the infection of the blood in acute general miliary tuberculosis, and thus, as far as our theme is involved, furnish the starting-point for infection of the heart when this is involved in such cases, and it usually is so involved.

Lion<sup>15</sup> of Paris, in an able essay on "Experimental Endocarditis," experimentally proved the mode of infection, its presence and the character of nodules in tuberculous endocarditis, demonstrating that care in staining methods often determines, not only the question of their existence, but also of the tuberculous character of the nodules, even when invisible to the naked eye. Careless staining, and even indifferent work, are certainly responsible for many negative results.

#### TUBERCULOSIS OF THE MYOCARDIUM.

It is quite interesting to note the discrepancy of opinions prevailing with reference to the occurrence of tubercle of the myocardium. Kreysig,<sup>16</sup> writing in 1814 in Berlin, says: "Tubercular tumours of the heart walls, while met with very rarely, are very probable." Piory<sup>17</sup> said (25 years later): "Tubercles of the heart are very rare. Laënnec found three or four cases in which tubercles existed in the substance of the heart." Still further he says (in 1840): "Tuberculosis of the heart succeeds a general tuberculosis of the body, especially of the lungs. The rarity of heart tubercles is explained by the scarcity of cells or cavities (hollow spaces) between the muscular fibres of the heart. In one case in which a tubercular abscess had opened into the pericardium the tubercles lay outside of this membrane." Friedreich,<sup>18</sup> in 1867, said: "Tubercle occurs in the heart muscle in miliary form, in combination with miliary tuberculosis of other organs, often presenting such fine nodules that without the closest scrutiny one fails to recognise them, but appears under these circumstances and in this way more often than was hitherto generally believed (von Recklinghausen, Virchow, Klob). The large tubercular or cheesy nodules are met with in the heart muscle but rarely,

and, in fact, only in combination with chronic tuberculosis of other organs, especially of the lungs" (E. Wagner, Lüken, Waldeyer). Schroetter, in 1876, says in Ziemssen's Cyclopædia: "Tubercle of the heart occurs principally in the form of discrete miliary yellowish or greyish nodules in the connective tissue between the muscular fibres, aside from its occurrence as part of a general tuberculosis. Rarely do large cheesy nodules appear, and when present are a consequence of chronic tuberculosis usually penetrating from the vicinity (Waldeyer, Recklinghausen: Virchow's *Archiv*, xvi., 1859)." Townsend<sup>19</sup> found (1832) a large tuberculous nodule starting from the left auricle and compressing the pulmonary vein. Hartog,<sup>20</sup> writing in 1901, says: "It seems a pity that Weigert has not received the recognition due to him in clearing up this particular subject and the process of infection in acute miliary general tuberculosis." A year after Weigert called attention to the way in which cardiac tuberculosis had been overlooked, Sanger, in 1878, still insisted upon his own views, but a year later (1879) admitted Weigert to be correct, when the latter said that "acute general miliary tuberculosis was always accompanied by cardiac tuberculosis."

*The form in the myocardium.*—The forms in which tubercles appear in the myocardium are most commonly the fine transparent miliary nodules, at times greyish or yellowish, discrete or aggregated, as found in acute general miliary tuberculosis; again in the larger yellowish nodules, from pea to walnut size; rarely in large cheesy masses; least commonly of all as diffuse cheesy degeneration (Townsend's case was of this nature). When diffuse tuberculosis exists it is the result of infiltration of the muscular tissue by the tuberculous granulation tissue, which is soon transformed into a homogeneous cheesy mass, composed of a conglomeration of tuberculous masses.

*The favourite seat in the myocardium.*—Weigert<sup>21</sup> called attention to the fact that miliary tubercles occurred most commonly in the ventricles.

#### GENERALISATION IN TUBERCULOSIS OF THE HEART MUSCLE AND THE ENDOCARDIUM.

*Frequency of occurrence.*—Haberling<sup>22</sup> made a *résumé* of recent cases (in 1865) and has reported 12 cases. Schöffler<sup>23</sup> went over the same ground in 1873, and Sanger notes 19 cases of tuberculosis of the myocardium in Schöffler's report. Pollak finds 27 cases. Kaufmann<sup>24</sup> says that he found the smaller nodular form so often that he scarcely thought it worth referring to. Hartog<sup>25</sup> finds in modern literature, apart from the cases which I have noted above, only nine cases, and he adds one of his own in which the complete necropsy is reported.

*Diagnosis.*—The diagnosis was made but once during life, and then only some cardiac lesion was suspected, but not its exact nature. At the necropsy, or, should the diagnosis of tuberculous tumour become possible, in life, only a gumma could be mistaken for a large cheesy mass. In the smaller nodular form accompanying general miliary tuberculosis careful investigation at the necropsy and careful staining will furnish sufficient evidence. If the large cheesy mass is present, this usually accompanies general tuberculosis elsewhere in the body, mostly in the lungs, often in the bones (vertebræ) and joints, commonly in the glands. Here the presence of the general tuberculosis would make the diagnosis as to the nature of the cheesy mass quite easy.

*Age and sex.*—Infants generally furnish the miliary form already referred to. All ages may be affected. Old age furnishes the larger number of cases of cheesy nodules. Data are insufficient for the determination of the influence of sex, though the male sex predominates in the cases noted.

*The favourite seat.*—While the favourite seat in acute general miliary tuberculosis is the conus arteriosus of the right side, the great papillary muscle, and less frequently the endocardium of the ventricles, it is different in the small nodular form, which is not general, in which the ventricles are the favourite seat, and different again in the larger masses (caseous form), in which the auricles or the junction of auricles and ventricles and the ventricles (often near the septum) are the seat of predilection. <sup>25</sup> Loc. cit.

times, in cases in which pericarditis co-exists, the tumour may have gone by contiguity over to the myocardium and thus be seated anywhere.

*The mode of infection.*—The blood-vessels are most probably the main avenues of infection. The large percentage of cases in which tuberculous nodules are found in the myocardium in connexion with acute general miliary tuberculosis, and in which the blood-vessels are the avenues of infection, would certainly lead us to infer the same avenue in the less frequent cases. Again, the fact that the two varieties occur in different situations, or because in the one case we deal with minute, almost invisible, tumours, is no argument against the probable identical source of infection in all.

*Clinical history.*—Although two cases gave rise to indefinite local symptoms, no clinical picture worthy of attention can yet be adduced.

#### TUBERCULOUS PERICARDITIS.

The incentive to this paper was largely given by an interesting case of this kind seen by me some years ago. Fortunately, a still clearer and more beautiful specimen was placed at my disposal by Professor Bostroem of Giessen, to whose kind assistance I am indebted for the opportunity of studying a magnificently preserved specimen of which I append an account. A second case, the history of which is also briefly told below, is of importance as supporting a now generally accepted view as to the origin of the infection in tuberculous pericarditis.

**CASE 1.**—A man, 36 years of age, entered the surgical clinic at Giessen for a right-sided empyema. Nothing pointed to cardiac involvement during life, and beyond probable large heart area (presumably recognised) no suspicion of tuberculosis was entertained. At the necropsy the pericardial sac was enormously distended. The distended sac was 24 centimetres broad and 20 centimetres long. The outer parietal pericardial sac was covered with numerous grey miliary nodules which extended and covered a limited portion of the right pleura. The sac contained considerable thick bloody fluid—one and a half litres were emptied. The visceral pericardium was completely covered with a series of layers of greyish cheesy nodules, of fibrous tissue, mixed with serum and pus, and partly formed fibrinous layers. The whole formed a firm mass which was firmly adherent to the heart. The most striking feature was the layer of cheesy nodules, one millimetre in diameter, which was next to the heart muscle and formed a clearly distinguishable layer. Over this lay a layer, one centimetre in thickness, of young tuberculous granulation tissue, and upon this came the layer of fibrine mixed with sero-pus and blood. The right side, in the region of the fourth, fifth, and sixth ribs, was the seat of a sharply localised tuberculous sacculated empyema. The lung and the spleen contained a few tubercles. The tracheal and bronchial glands were enlarged and cheesy and the seat of anthracosis (the man was a miner). There is no doubt that the cheesy bronchial and tracheal glands were the starting points of the pericarditis, and that the latter had been excited by extension of the tuberculous glandular tissue.

**CASE 2.**—This was a case of tuberculous adhesive pericarditis. The patient, a woman, 68 years old, died from marasmus. At the necropsy atrophy and anemia of nearly all organs were found. The lungs were free from tuberculosis save for a few small old fibrous nodules. In no other organs was any tuberculosis found save in the following. The heart sac was totally adherent, and between the heart surface and the adherent pericardial wall greyish-yellowish tuberculous nodules covered the entire surface of the heart. The heart was atrophied. The cervical glands and the bronchial glands at the tracheal bifurcation were the seat of tuberculous cheesy degeneration which had destroyed much of the gland tissue. The gland tissue was pigmented. The tuberculous pericarditis was the sequence of the penetration of the cheesy degenerated bronchial glands into the pericardial sac which was adherent to the heart by tuberculous pigmented tissue.

*Etiology.*—While spontaneous tuberculous pericarditis is not denied as a possibility, its probability is considered more than doubtful. The more thorough the investigation of a given case the fewer will be the idiopathic cases and the greater the number of cases in which some preceding infection will be found. Zenker<sup>26</sup> years ago pointed out the fact that in 54 cases of oesophageal ulcers caused by diseased

lymph glands, 10 cases of pericardial adhesion were found. In 1879 he confirmed the relation between diseased mediastinal and bronchial glands and the pericarditis. Kast reports a case of Zahn's of purulent pericarditis with perforation of cheesy bronchial glands into the pericardial sac. Weigert<sup>27</sup> has also called attention to the fact that the serous membranes generally when infected with tuberculosis acquire the disease by contiguity from a neighbouring organ. Special attention is called not so much to the bronchial glands as to the set of small mediastinal glands seated below the bifurcation of the trachea, and above the place of folding over of the pericardial sac as the source of irritation of the tuberculous pericarditis. These glands first become tuberculous and then invade the pericardium by extension. Kast quotes cases of Bäumlér and Schottelius, confirming this mode of infection.

*Age and sex.*—Nothing is characteristic in tuberculous pericarditis as to age and sex, except that even old persons may have this form of pericarditis.

*Form.*—The usual characteristics of tuberculous pericarditis are too well known to require repetition here. As an unusual phenomenon we find the arrangement of cheesy nodules in a complete enveloping layer, as evidenced in Case 1 referred to by me. An additional interesting form is the pigmentation in Case 2.

*Clinical history.*—While a large number of cases of tuberculous pericarditis are recognised during life, they are rarely, if ever, of the class of which we speak here. The possibility that even in advanced life, if ever cheesy glands have existed, such a sequence is possible, should be borne in mind.

*Staining methods.*—Wechsberg<sup>28</sup> gives two excellent staining methods which he used in the laboratory of Weigert and in that of Ehrlich. In his second method he succeeded with a general tissue stain, including cell nuclei and protoplasm, connective tissue and elastic fibres, without clouding the bacillus stain in the least. It must be remembered that Wechsberg worked with the very fresh comparatively delicate tissues of recently-killed infected rabbits. For fixing and hardening alcohol was generally employed, only the eyes were hardened for one or two days in 10 per cent. of formal. Some preparations were fixed in Flemming's solution and coloured with safranin to make the proliferating nuclear appearances more distinct. The tissues were subsequently imbedded in the usual manner, partly in celloidin and partly in paraffin. The staining methods were as follows:—(A.) 1. Section staining for one hour at 37° C. in thermostat in carbol-fuchsin. 2. Differentiation in muriated and 70 per cent. alcohol (1 and 2 were bacilli stains). 3. Staining with Delafield and van Gieson hæmatoxylin in usual manner (van Gieson). 4. Absolute alcohol, xylol, and balsam. In such sections the bacilli were dark red, the cell nuclei blue or blue-violet, the cell-protoplasm yellowish-brown, the connective tissue pale red. (B.) 1. Staining of sections for an hour at 37° in carbol-fuchsin. 2. Differentiation in muriated and 70 per cent. alcohol (1 and 2 bacilli were stains). 3. Section staining for one hour in Weigert's solution for colouring elastic fibres. 4. Rinsing in 96 per cent. alcohol (3 and 4 were elastic fibre stains). 5. After colouring in lithium carmine and washing with muriated alcohol (for contrasting colouration, nuclei and protoplasm colouring). 6. Absolute alcohol, xylol, and balsam. In these preparations the bacilli were dark red with a tinge of violet; the elastic fibres were dark blue; the remaining tissues of the contrasting colouration were light red with more darkly-stained nuclei. Care must be taken not to make the lithium carmine staining too intense; the red bacilli staining was always clearly recognisable against the violet-tinted red ground-work. Hartog<sup>29</sup> mentions the following process applied to a large tumour mass of tuberculous tissue from the human subject. A piece was hardened in 10 per cent. formal, then placed in 96 per cent. alcohol, and finally in absolute alcohol. The pieces were then put in alcohol-ether and imbedded in celloidin. Sections of 0.015 millimetre thickness were then stained after the von Gieson method. Finally coloured with the Weigert stain for elastic fibres.

## THE DETENTION OF LUNATICS IN WORKHOUSES.

By SYDNEY DAVEY, B.A., LL.B.,  
BARRISTER-AT-LAW.

THERE has for some time past existed in the minds of the medical officers of workhouses considerable doubt as to the true interpretation of those sections of the Lunacy Acts which relate to the detention of lunatics in those institutions. The opinion of the Law Officers of the Crown has recently been taken by the Commissioners in Lunacy on the more important questions that have arisen, and there is no doubt that their opinion is contrary in many respects to that which has generally prevailed hitherto. It is therefore of the greatest concern to medical officers of workhouses that they should thoroughly appreciate the opinion of the Law Officers, more particularly as the matter is one that touches the liberty of the subject and is accordingly jealously regarded by the law.

Now, the most important question, perhaps, that has arisen is as to the effect of Sub-section 1 of Section 21 of the Lunacy Act, 1890, which provides that:—

In any case where a summary reception order might be made, any justice, if satisfied that it is expedient for the welfare of the lunatic, or for the public safety, that the lunatic should forthwith be placed under care and control, and if it appears to him that there is proper accommodation for the lunatic in the workhouse of the union in which the lunatic is, may make an order for taking the lunatic to and receiving him in that workhouse.

It has been a very common practice during the past few years for an order to be made under this sub-section, which authorises the detention of the lunatic in the workhouse for not more than 14 days, irrespectively of the fact whether the lunatic at the time of making the order is in the workhouse or not. The advantage of adopting this course is to give the workhouse authorities a longer time for watching the lunatic and so determining what may best be done with him. And, too, when the insanity proves of a very temporary character so that a short confinement is sufficient, the expenses of conveying a lunatic to an asylum under a summary reception order may be saved. But the opinion of the Law Officers is that an order cannot be made under Sub-section 1 of Section 21 in respect of a lunatic already in the workhouse. This view applies to a lunatic who has been removed to the workhouse by a constable, relieving officer, or overseer under Section 20 of the Act, and to a pauper inmate who has become insane during his residence in the workhouse, or who has, as a lunatic, ceased to be a proper person to be detained in the workhouse. In all these cases, accordingly, when the lunatic is brought before the justice, the justice must make his examination then and there; and, although he may find it necessary to adjourn the examination, he cannot issue an order under Sub-section 1 of Section 21.

Where, however, a justice makes an order with respect to a lunatic under Sub-section 1 of Section 21—this order, as it is said, being applicable only to the case of a lunatic not already in the workhouse—the lunatic may be detained for a further period of 14 days under a certificate of the medical officer of the workhouse made in accordance with Section 24 of the Act. A certificate under this section must certify: (a) that the person detained is a lunatic, with the grounds for the opinion; (b) that he is a proper person to be allowed to remain in a workhouse as a lunatic; and (c) that the accommodation in the workhouse is sufficient for his proper care and treatment separately from the inmates of the workhouse who are not lunatics, unless the medical officer certifies that the lunatic's condition is such that it is not necessary for the convenience of the lunatic or of the other inmates that he should be kept separate. (The medical superintendent of an asylum provided for the reception and relief of the insane under the Metropolitan Poor Act, 1867, is not required to certify to the effect in (c), although such asylums are in general subject to the Lunacy Acts.) Then, unless an order commonly known as a "permanent detention order" has been obtained from a justice under Sub-section 4 of Section 24 for the detention of the lunatic in the workhouse beyond the period of 14 days during which the certificate of the medical officer remains in force, the medical officer must at the expiration of the 14 days "give notice in writing to the relieving officer of the union to which the workhouse belongs," and "thereupon the like proceedings must be taken by the relieving officer and all other persons for the purpose of removing the lunatic

to an asylum, and within the same time, as by the Act provided in the case of a pauper deemed to be a lunatic and a proper person to be sent to an asylum, and, pending such proceedings, the lunatic may be detained in the workhouse." (Section 24, Sub-section 6.)

Sub-section 2 of Section 21 of the Lunacy Act, 1890, provides that "in any case where a summary reception order has been made an order under this section may be made for the detention of the lunatic until he can be removed." The Law Officers answer negatively the question—Can a lunatic who has been taken to and detained in a workhouse under Section 20, Sub-section 1, be further continuously detained for another period of 14 days under Sub-section 2 if a justice makes an order on the last day of the first period of 14 days for the removal of the lunatic to an asylum and then makes an order under Sub-section 2 directing the detention of the lunatic in the workhouse pending removal to the asylum? Here, too, the opinion of the Law Officers is at variance with the practice which has hitherto been very common of making orders with respect to the same lunatic under both Sub-section 1 and Sub-section 2 of Section 21. Again, the Law Officers are of opinion that a lunatic detained in a workhouse for 14 days by an order under Sub-section 2 of Section 21 may be further continuously detained for another period of 14 days under a certificate given by the medical officer of the workhouse under Section 24.

Finally, when a lunatic is in a workhouse, if the medical officer does not sign a certificate under Section 24; or if at or before the expiration of 14 days from the date of the certificate an order is not made by a justice for the detention of the lunatic in the workhouse; or if after such an order has been made the lunatic ceases to be a proper person to be detained in a workhouse, pending the proceedings that are required to be taken under Sub-section 6 of Section 24, the Law Officers are of opinion that the lunatic may be detained for the following consecutive periods: (a) for the three days within which the relieving officer must, under Section 14, give notice to a justice that a person resident in his district is deemed to be a lunatic; (b) for the further period of three days which may elapse before the alleged lunatic is brought before a justice; and (c) after a summary reception order has been made for a further period of 14 days under Sub-section 2 of Section 21 pending the removal of the lunatic to the asylum.

## THE PREVENTION AND CURE OF PHTHISIS.

By GODFREY W. HAMBLETON, L.K.Q.C.P. IREL.

THE object of this paper is to give a brief outline of a practical and effective system of prevention and cure of phthisis and to advocate its general adoption.

We are, I think, agreed that phthisis is due to a toxin, but we differ as to its source of origin. The view generally accepted is that the toxin is directly or indirectly produced by the bacillus tuberculosis. My experiments and observations, commenced in 1873, have proved to me that it is a natural product, normally present in, and eliminated from, the body, and that its accumulation in the system is produced by an inadequate respiratory surface of the lungs not compensated for by the supplementary vicarious action of other organs, due to certain definite physical conditions—viz., those that directly or indirectly tend to reduce the breathing capacity. The difference between these views is of cardinal importance. In the former case I have yet to hear of any satisfactory practical result, directly due thereto, either in prevention or treatment, and that was, I knew, inevitable. But in the latter we stand on firm ground, for we have definite attainable objects and know the means by which we can obtain them.

The object to be attained in the prevention of phthisis is to secure the complete elimination of the toxin by the lungs by having an extent of respiratory surface adequate, not only to perform their ordinary functions, but also to meet within certain limits any extra demands that may be made upon them. A chest girth of, or nearly approaching to, Brent's medium standard—it corresponds very closely with Allen's tables for first-class life assurance—a range of movement of four inches, and a vital capacity exceeding Hutchinson's standard, indicate its presence. I have shown that the size and shape of the thorax depend upon the conditions to

which they are subjected. To develop the thorax we must avoid as far as possible those conditions of our habits, mode of life, and surroundings that tend to reduce the breathing capacity—the phthisisgenic conditions—and where they are unavoidable we must ascertain their amount and counteract their effects by the adequate introduction of conditions that tend to develop the breathing capacity—the non-phthisisgenic conditions—so that the tendency of the whole is markedly to develop the thorax.

In 1888 the Polytechnic Physical Development Society was formed to give a practical demonstration of the prevention of phthisis by adequate development of the lungs. Over 50 different trades and occupations were represented in the society. There were clerks, compositors, printers, watch-makers, carpenters, engineers, drapers, tailors, warehousemen, &c., who were engaged therein from eight to 12 and 14 hours daily. The average increase of the chest girth of 100 members was 2 inches, that of the first class was 3½ inches. Increases of 4½, 5, and 6½ inches have been recorded. The average range of mobility was about 4½ inches and a mobility of from 5 to 6 inches and upwards was frequently observed. Hutchinson's standard of vital capacity was considerably exceeded—an excess of 100 cubic inches and upwards has been noted—and in respiratory power the majority belonged to or exceeded his "remarkable" and "very extraordinary" classes. Brent's medium standard had been exceeded by 3.32, 3.42, and 3.67 inches, and many members had attained it. Now, that standard is 5.40 inches above the average of the artisan class and 3.17 inches above that of the most favoured class. The society has therefore shown that the conditions to which its members were subjected were so arranged that their tendency as a whole was to develop markedly the lungs, and it has proved the prevention of phthisis in the case of many members who were threatened with an early attack of the disease.

The objects to be attained in the treatment of phthisis are to eliminate the toxin and prevent its further accumulation and to develop the lungs to an adequate extent. A great step in the right direction has been taken by the open-air system of treatment, for it does cause an elimination of the toxin, but only passively and to a too limited amount. We must actively eliminate the toxin and prevent its further accumulation by increasing the functional activity of the skin, kidneys, and alimentary canal, by baths or by sponging the whole body, and by the use of diaphoretics, diuretics, and saline aperients. The amount of this vicarious action and the organs to be selected depend upon the extent of the disease and the state of the patient. In the early stage I have found the prescription of two baths daily and three doses of an alkaline mixture containing diaphoretics and diuretics, with a saline aperient in the morning and later tonics, amply sufficient.

I need not say that great care must be taken to secure good personal and general hygienic conditions for the patient. His food must be good and the appetite must be cultivated—not forced. He must spend as much time as possible in passive and, as soon as he is able, active exercise in the open air. No attempt must be made actively to develop the lungs until the disease has been some time arrested, then active measures may be gradually adopted and progressively increased, care being taken to avoid either strain or over-exertion until the full development of the lungs has been obtained.

By this system of treatment in the early stage the chest symptoms are immediately relieved, cough and expectoration disappear, the area of breathing, vital capacity, chest girth, and mobility increase, the temperature tends to normal, weight increases, the general state improves, and there is the appearance of a certain amount of health and strength. This is followed by complete arrest of the disease, the absence of all symptoms, an increasing area of breathing capacity, normal temperature, fair weight, good general health, and ultimately by complete recovery. There has so far been no failure in that stage and, except for error in diagnosis or treatment, all such cases ought to recover. By complete recovery I mean the possession of an adequate respiratory surface and sound health.

I have applied the treatment in over 50 cases and in all stages of the disease. Of these 10 patients have died, nine are reported well, and 16 have completely recovered—their average chest girth being (males) 37½ inches, expansion four and a half inches—an increase of two and three-quarter inches and two and a half inches respectively. The recoveries have been verified by post-mortem evidence, by acceptance for first-class life assurance in two cases, by the

number of years that have since passed in others (from two to 15 years), and I recovered in 1876.

*Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.*—MORCAESI De Sed. et Caus. Morb., lib. iv., Proœmium.

### MAUD HOSPITAL, EXMOUTH.

#### A CASE OF PAROTITIS FOLLOWING AN OPERATION FOR APPENDICITIS.

(Under the care of Dr. R. STANLEY THOMAS.)

THE connexion between inflammation of the parotid gland and abdominal disease or operation has been recognised for many years and the abscess which generally formed was looked upon as pyæmic. It was shown by Mr. Stephen Paget that this explanation would not suffice, as in the majority of the cases in which it occurred abdominal disease was present. The chief argument against this parotitis being pyæmic in origin is the fact that it is extremely rare for any other manifestation of pyæmia to be present. Mr. A. Quarry Silcock has offered a very probable explanation of the occurrence of a parotid bubo, as this parotitis is unwisely called.<sup>1</sup> He suggests that in most of these cases very little food is taken and the mouth becomes dry and septic and that micro-organisms spread along the duct of Stenson. In favour of this theory is the fact that parotitis is by no means rare after typhoid fever.

A young woman, aged 22 years, whose occupation was that of a general servant, was taken ill suddenly with severe pain in the abdomen at 11.30 A.M. on Oct. 20th, 1901. When seen at 3 P.M. she had great pain which was referred to the region of the umbilicus, with very marked tenderness in the right iliac region. The percussion note was resonant over the whole of the abdomen, but there was distinct resistance in the right iliac region. The temperature was 102° F. and the pulse was 120. The girl had had two similar attacks—one in October, 1900, and one in June last. Both attacks came on suddenly and were accompanied by pain and sickness, and in both instances she was laid up for five weeks.

The patient was removed to the Maud Hospital, Exmouth. Hot fomentations were applied to the abdomen and she was given a pill of a quarter of a grain of extract of opium with a quarter of a grain of extract of belladonna every four hours and a liquid diet. On Oct. 21st she was in much the same condition, being in considerable pain and frequently sick. On the 22nd she was apparently much worse and could keep nothing down. The temperature was 100.4° and the pulse was 120. At 3.30 P.M. she was operated on, the A.C.E. mixture being given by Mr. O. Eaton and Mr. R. Martyn kindly assisting Dr. Thomas. The appendix was found with its apex firmly adherent to the brim of the pelvis; owing to the great distension of the bowels with gas it was difficult to reach, but it was, by means of an aneurysm needle, ligatured in two places and then divided. As nothing else was found the abdomen was closed. At 7 P.M. the temperature was 97.8° and the pulse was 100. The patient was free from pain and quite comfortable. The bowels acted after an enema on the second day. Parotitis developed on the sixth day on the right side and was extremely painful, persisting for 10 days. On the nineteenth day there was slight suppuration of the superficial stitch holes. Except for this the patient made an uninterrupted recovery and left the hospital at the end of six weeks.

*Remarks by Dr. THOMAS.*—In this case the inflammation of the parotid gland occurred on the sixth day after operation for an adherent appendix. There was no sepsis to account for it, although there was some suppuration of the stitch holes 19 days after the operation which could not be accounted for. The parotitis lasted 10 days, during which time the temperature kept between 100° and 101°; it subsided without suppuration.

## Medical Societies.

### HUNTERIAN SOCIETY.

#### *Discussion on Small-pox and Vaccination.*<sup>1</sup>

A SPECIAL meeting of this society was held on Nov. 13th, Dr. DUNDAS GRANT, the President, being in the chair.

Dr. J. MACCOMBIE read a paper upon the Differential Diagnosis of Small-pox which will be found fully reported at p. 1785.

Dr. MACCOMBIE also read a communication upon Vaccination. He said: With the ethical aspect of vaccination I do not intend to deal. My observations are based solely upon small-pox hospital statistics and my own hospital experience. The hospital case-mortality in unvaccinated small-pox patients is about 45 or 50 per cent., in vaccinated patients it is about 8 per cent. The severity of an attack of small-pox in vaccinated subjects bears, as a rule, a distinct relationship to the quality of the vaccination scars. The basis on which most of the small-pox hospital statistics in London were compiled in the past was the number and quality of vaccination marks. On this basis the case-mortality per cent. in 11,724 cases of small-pox in vaccinated subjects treated in the Asylums Board Hospitals was as follows:—

	Per cent.		Per cent.
One good mark ... ..	6.4	One indifferent mark ...	16.7
Two .. marks ... ..	3.7	Two .. marks... ..	11.2
Three .. ..	3.7	Three .. ..	7.4
Four or more good marks...	2.7	Four or more indifferent marks ... ..	4.8

The case-mortality is therefore inversely proportioned to the number + quality of marks, ranging from 16.7 per cent. in those showing one indifferent mark to 4.8 per cent. in those showing four or more indifferent marks, while in those showing good marks the case-mortality ranges from 6.4 per cent. in those showing one good mark to 2.7 per cent. in those showing four or more good marks. When I was treating small-pox at the South-Eastern Hospital it appeared to me to be desirable to obtain some statistics of small-pox based on the actual area of vaccination surface, regard being had also to foveation. With this in view I measured the extent of vaccination scar-surface in 5808 consecutive cases of small-pox. At that time the Local Government Board standard of efficient vaccination was not less than one-third of a square inch of well-foveated surface. I adopted that as my standard. All patients showing imperfectly-foveated surface, no matter how great the area, were regarded as inefficiently vaccinated. The results were as follows:—

	No. of cases.	No. of deaths.	Mortality per cent..
Efficiently vaccinated ...	1435	36	2.7
Inefficiently vaccinated ...	4373	378	8.7

These figures appear to me to show the solid advantage of extent of vaccination scar-surface + quality of surface in lessening the fatality of small-pox. During the years that I was in charge of a large small-pox hospital the protection afforded to the officers, nurses, and servants against small-pox by vaccination and revaccination was remarkable. A very large number were employed. Two only contracted small-pox, one nurse and one ward-maid. The nurse was a determined anti-vaccinationist, as I found out afterwards. During the pressure of work she somehow escaped revaccination. She had a mild attack of unmodified small-pox. The ward-maid had been revaccinated by me three times unsuccessfully. She had a very mild attack of modified small-pox. Indeed, had it not been for the protection afforded by vaccination and revaccination against small-pox it would have been impossible then, as it would be impossible now, to obtain nurses and others for small-pox hospitals. Small-pox does, however, occur in a very few persons who show scars of successful revaccination. Though none of my staff whose re-

vaccination had been successful contracted the disease I have had under my care patients who showed scars of successful revaccination, but I have not seen small-pox in a person who had been efficiently vaccinated—i.e., who showed one-third or more of well-foveated primary vaccination surface and who showed also marks of revaccination. Even an attack of small-pox does not in some rare instances protect against a second attack.

Dr. MAJOR GREENWOOD read a paper upon the Present Aspect of Small-pox and Vaccination, making special allusion to Dr. Creighton's article in the Encyclopædia Britannica. Three indictments were made against the author of this article: (1) the facts which he reported by no means necessarily supported his deductions; (2) he enlarged upon those facts which seemed to tell against vaccination and dismissed briefly those seeming to favour it; and (3) different facts standing on vastly different bases were treated as of equal value. Dr. Greenwood then showed the looseness of the evidence upon which Dr. Creighton founded his conclusion, especially that certain diseases, including jaundice, were caused by vaccination. Dr. Creighton appeared to believe that syphilis was originated *de novo* from cow-pox. He had attributed the decrease of small-pox to a change in the type of the disease, but this cause, if it existed, would scarcely explain the great diminution of small-pox in children compared with that in the general population. Dr. Creighton alleged that there was no diminution in mortality amongst small-pox patients, as this, according to statistics, was the same in the eighteenth century as at the end of the nineteenth—viz., 18 per cent. It was, however, contended by Dr. Greenwood that statistics as to the mortality from small-pox compiled during one of the old epidemics would be quite untrustworthy. The Conscience Clause had caused the law to be treated with contempt and it amounted practically to a repeal of the vaccination laws. Experience gained since the passing of the last Vaccination Act taught the following lessons. 1. That it was no good throwing sop to the anti-vaccinationist—he intended war to the knife with vaccination in any form. 2. That boards of guardians ought to have nothing to do with the administration of vaccination laws. If those laws were entrusted to any local authority it should be to the borough council, to the health department of which it naturally belonged, but it would be better still to put it under the control of some central authority not likely to be influenced by local prejudice. 3. That the vaccination officer ought to be free from the control of any local authority and answerable only to the Local Government Board or the central vaccination authority, whose inspectors ought to report periodically how his duties were being carried out. 4. That they had in vaccination as now practised a protective inoculation against small-pox as powerful and trustworthy as was that introduced by Lady Mary Wortley Montagu, and without any of its dangers to the patient or risk of spreading the disease to others. 5. That experience taught that to be efficient the area of vaccination must be not less than half a square inch; that revaccination in adult life was always necessary; that in some cases vaccination at intervals of 10 years might be required to give adequate protection; and that the so-called "one spot" vaccination was greatly to be condemned. 6. That an efficiently vaccinated person rarely, if ever, contracted small-pox however much he might be exposed to infection. 7. That when vaccination was performed with antiseptic precautions and with suitable calf-lymph the danger of introducing other diseases was practically nil. 8. That no general sanitary measures could take the place of vaccination as a protective against small-pox. 9. That compulsory vaccination of the infant community was most desirable, and that it was the duty of the medical profession to lose no opportunity of pressing this fact both on the public and on the Legislature.

Dr. W. ARTHUR BOND, medical officer of health of Holborn, submitted a communication upon vaccination. He said that it was the general experience that nurses and the staffs of small-pox hospitals might with almost complete impunity be much exposed to infection provided they were efficiently revaccinated. In the Metropolitan Asylums Board Hospitals there had been no case of small-pox during the past seven years, 1894-1900 inclusive. Also in the previous 10 years there had been no case, the apparent exceptions being persons who were attacked before successful revaccination had been effected. During the 35 years preceding 1871 there had been no case of small-pox among the nurses and servants of the Highgate Small-pox Hospital. Since then the only case had

<sup>1</sup> Our report of this debate has been unavoidably delayed. The matter, however, is as interesting now as it would have been a month ago.—ED. L.

been that of a gardener who had not been revaccinated. So that there was a record of nearly 60 years, with the one apparent exception just mentioned. Other small-pox hospitals gave similar results. The fatality of small-pox amongst the vaccinated was much less than it was amongst the unvaccinated. In London during the past 10 years (1891 to 1900) of the vaccinated of all ages the percentage of deaths of those attacked was 3.1; of the unvaccinated it was 18.8. Even if all the doubtful cases that had no evidence of vaccination and the majority of which were most probably unvaccinated were included amongst the vaccinated the percentage of deaths was only 4.8, against 18.8 amongst the unvaccinated. In Leicester of 198 vaccinated persons of all ages who were attacked the only death was that of a hospital laundress, aged 45 years, an intemperate woman who refused revaccination and showed two marks of vaccination in infancy. Of 154 unvaccinated persons 19 died, or a mortality of 12.3 per cent. If the age-period under 10 years of age were taken, when vaccination had greater protective power, the contrast of the fatality amongst the vaccinated and unvaccinated was still more striking. [As bearing upon this part of his subject Dr. Bond submitted the following table.]

*Vaccination Statistics of some Large Towns.*

	Total number of cases of small-pox.	Under 10 years of age.					
		Vaccinated.			Unvaccinated.		
		No.	Number of deaths.	Death-rate.	No.	Number of Deaths.	Death-rate.
London, 1891-1900 ...	5,166	125	—	—	672	153	22.8
Leicester, 1892-1893 ...	357	2	—	—	107	15	14.0
Sheffield, 1887-1888 ...	4,703	353	6	1.7	228	100	43.9
Dewsbury Union, 1891-1892 ...	1,029	44	1	2.2	174	56	32.1
Warrington, 1892-1893...	667	33	2	6.0	32	12	37.5
Gloucester, 1895-1896 ...	1,979	26	1	3.8	680	279	41.0
Manchester, 1892-1893 ...	805	11	—	—	36	7	19.4
Oldham, 1892-1893 ...	124	3	—	—	15	5	33.3
Leeds, 1892-1893 ...	200	4	—	—	8	3	37.5
Halifax, 1892-1893 ...	330	4	—	—	38	15	39.5
Bradford, 1893 ...	658	17	—	—	57	23	40.3
Totals ...	16,018	622	10	1.6	2,047	668	32.6

In these statistics the vaccinated included all that had any evidence of vaccination, good, bad, and indifferent, and some in which there was no good reason for believing that they had been vaccinated at all. The statistics of these epidemics of small-pox also showed that the attack-rate amongst the vaccinated was very much less than it was amongst the unvaccinated, also that the type of the disease was much less severe amongst the vaccinated. The statistics which Mr. Marson had given of nearly 14,000 cases of small-pox, and those of many thousands of cases by other observers, showed that four or more vaccination marks afforded much greater protection than only one mark, and the fatality amongst those with only one mark was much less than it was amongst the unvaccinated. Statistics of various observers had shown that there was superior protection according as the area of the vaccination marks was larger. It might therefore be stated as a general law—The better the vaccination the greater the protection against small-pox and mortality from that disease. Touching the value of revaccination Dr. Bond put forward the following statistical facts. Concerning the London postal service, in the period from 1870 to 1880 inclusive, and embracing the time of the epidemic of 1871, only 10 slight cases of small-pox occurred, not one of them being fatal (average, 10.504). In Sheffield and Warrington in the postal service and the police force there had been no attack among the revaccinated. Since 1874, when revaccination became compulsory throughout Germany, there had been very few deaths from small-pox. In the army no death from that disease had occurred.

Dr. BOND, in opening the discussion upon the subject before the society, remarked that erythema multiforme was a disease very likely to be mistaken for small-pox under certain conditions. He saw one case two years ago about which he was very doubtful; he did not think that it was a case of small-pox, but thought that it ought to be seen by an expert on small-pox, and as the case was that of a poor patient the sufferer was removed to the wharf and he was not surprised to find that the patient was sent back. In these cases fever and eruption on the pharynx and palate were often met with, and in some cases the eruption was very similar to that of small-pox, and the above no doubt was a case of erythema multiforme. Of course, as had been mentioned by Dr. MacCombie, the disease which was most often mistaken for small-pox was chicken-pox. He was very glad to have had the privilege of hearing Dr. MacCombie's paper and also Dr. Greenwood's.

Dr. RICHARDS, medical officer of health of Finsbury, said that they had had altogether in Finsbury 44 cases of small-pox in the present epidemic, nearly all of which had arisen from two groups—those which were at first mistaken for chicken-pox and those which were not. Out of the 44 cases there were 12 unvaccinated patients, three of whom died, and 32 had only been vaccinated in infancy, and not a single case had occurred in which the patient had been revaccinated. He asked whether Dr. MacCombie would have considered the following case to be one of small-pox. He had had a case notified from a house, and in that house there had been about a fortnight before a girl who had presented all the initial characters of small-pox but no rash at all. She said that she had a cold and nothing further happened, but the sister who slept with her had come out in unmistakable small-pox. He presumed that the former was a case of small-pox without the rash.

Mr. ST. GEORGE CALDFIELD REID, medical officer of health of Croydon, showed some photographs of cases of small-pox made by Mr. Marriott, the medical officer of Leicester, during the year of the epidemic of small-pox in Birmingham. He mentioned the difficulties there were for procuring lymph that was absolutely above suspicion. Personally he thought that it was a very great mistake that the Local Government Board did not provide both medical officers of health and general practitioners with Government lymph. He thought that they should be very careful not to exaggerate the power of primary vaccination; a great deal of harm had been done by the popular idea that primary vaccination was enough for the rest of life. He would like to know from some of the members present what rules they enforced for revaccination, his rule as to the hospital staff being two years, and as to the general public 10 years.

Dr. G. NEWTON PITT said that some few years ago he was asked to see a case in which the patient had two spots and to decide as to whether it was a case of small-pox, and he would like to ask Dr. MacCombie's opinion about it. In this particular case the patient had a spot on the face and a spot just below the chin. He was called in by a practitioner who had had a very large experience of small-pox, whereas his experience was extremely small. He said that in such a doubtful case the best thing was to get one of the authorities from the small-pox ship. He did not know what was the final conclusion, but the question was that if there were two or three spots were they likely to be in one particular locality? Another question was that if they were limited to two spots would there almost certainly be a normal temperature?

Dr. R. K. BROWN, medical officer of health of Bermondsey, said that he did not remember whether Dr. MacCombie mentioned in his paper that the rash was more likely to come out in small-pox patients at any particular point. For instance, he had had several cases in his district of patients who had been vaccinated and who had within 24 hours developed small-pox, and he found that the rash was more likely to be prevalent at the points of the vaccination. Another question that he never could understand was what was meant by the area of the vaccination scars being half a square inch? He did not really see what point was taken to measure the scars from.

Dr. T. GLOVER LYON said that he would like to have a definite answer to the question of revaccination. He wanted to know whether two good vaccinations were enough. Just before the meeting the librarian of the institution had put into his hands two books, which he thought would be found interesting. The writer said that

in India there was a goddess of small-pox; her name was Amma, which meant "mother." She was a great and benign goddess who showed her anger by producing small-pox. The librarian had been a magistrate in India and had often had before him people with small-pox giving evidence in a court of law.

A VISITOR said that he had been rather astonished that so many people should be glad to hear a discussion on small-pox and vaccination when they came to consider that in Germany small-pox did not trouble them nowadays; it was, practically speaking, wiped out. By taking the statistics as they occurred from year to year it would be found that as a rule in Prussia itself the cases of small-pox nearly always occurred on the frontier. He thought that there was scarcely ever a death from small-pox in the army nowadays, at all events in the Prussian army; vaccination, however, really was compulsory before two years of age, after 12 years of age, and for a soldier when he joined the army.

The PRESIDENT said that in the early part of his practice in London he had of course come in contact with small-pox. He remembered that one of his very earliest experiences was being called into a house where were lying in bed two young men with a number of abscesses all over their bodies and apparently struggling for their lives; two others in this family had recovered and two had died. He said to the father of the patients: "This says very little for vaccination." The man replied: "I have been a very foolish man; the fact is I have always considered that my blood and my wife's blood were so pure that we would not have it mixed with any contamination whatever. The result is that I have lost two of my family, and the only member who has escaped is the little baby who has been vaccinated." On another occasion he (the President) was called in to a family of poor people who had come from the north, in which a number of the members of the family had been vaccinated and the others had not been vaccinated. The disease was practically confined to those who had not been vaccinated, and to the best of his recollection there was one death among these. These were experiences which he did not think anyone could forget or fail to be impressed by. He thought that there must be many more members of the profession who had witnessed such occurrences, and perhaps if they were published they would have some weight in helping to carry along public opinion. Another instance which he remembered very distinctly was that in Edinburgh, at a large firm of drapers, all the employés there were vaccinated with the exception of one. This was a young girl who was rather proud of her appearance and she was selected by small-pox to be disfigured for the rest of her life. He remembered in reference to prodromal rashes being thoroughly taken in by a case to which he was called by a young practitioner whose father's housekeeper had been taken ill. He found a scarlatinal rash on the trunk and he said: "Well, the symptoms are the symptoms of small-pox, but the rash is the rash of scarlet fever." He need hardly say that the rash was really the prodromal rash of small-pox. Before they went further he proposed a hearty vote of thanks to Dr. MacCombie, Dr. Greenwood, and Dr. Bond for the material which they had brought forward.

Dr. MACCOMBIE, in reply, said that erythema multiforme was not a disease that was much mis-diagnosed for small-pox at the time that he was dealing with small-pox. They had morbilliform erythemas and erythemas of shell-fish eruptions, but what struck him in all these cases was the absence of the initial symptoms of small-pox, and that was really the point on which an observer relied for the differential diagnosis of these diseases. If a doubt existed about a case the patient would be taken in and isolated for a day or two. Dr. Richards had mentioned an exceedingly interesting case of variola sine variolis—that was, small-pox without eruption. He had noticed in the cases of officers who looked after small-pox patients, that a fortnight or three weeks after they had entered on their duties some few would be laid up for a couple of days with very pronounced symptoms—headache, anorexia, and rise of temperature. This would last for two days more or less, then the temperature would fall and they would be quite well. They had the initial symptoms of small-pox without any small-pox showing itself. He had had a similar instance to that described by Dr. Richards. A patient was sent to him from somewhere in the East-end. Her temperature was normal and she felt perfectly well, but she gave a most explicit history of two days' initial symptoms of small-pox. He had learnt afterwards from the medical man

who had been attending her that the patient had had a rise of temperature and that there had been some initial rash, but there was no small-pox vesicle to be found on the skin. At the time of seeing the patient he had not had this information, but simply had her statement as to other symptoms. He could find no trace that she was then suffering from small-pox and accordingly he sent her home at once, as there was very little small-pox in London. About 14 or 16 days later, however, her sister was sent to him with undoubted small-pox, and he was inclined to think that small-pox without eruption could convey small-pox. He was very interested to hear of Dr. Richards's similar case. Mr. Reid had inquired how often it was customary to vaccinate the staff. That varied a good deal. From his observation of small-pox after revaccination it had been very evident that there were two classes—those in which small-pox occurred after revaccination with good primary marks and those with imperfect marks of vaccination. Accordingly, he had no regular rule as to revaccination of the staff. If they had good marks of primary vaccination and had been once successfully revaccinated after puberty he had let them go for years without being revaccinated again; but if they had imperfect vaccination marks, or a too small amount of primary vaccination marks, he would revaccinate them every three or four years. In his own case he had got one very bad primary mark. He had been revaccinated about 10 times and only once had it taken, and he had not been revaccinated for 15 years. Dr. Newton Pitt had mentioned a case of small-pox with two spots, one on the face and one on the chin; he did not gather whether there had been the initial symptoms of small-pox. [Dr. Newton Pitt here said that there were a premonitory rash, headache, a rise of temperature, and anorexia.] Dr. MacCombie, continuing, said that that was what might be expected in such a mild case; in a case with a considerable amount of eruption there never was any pyrexia. With only two spots it would be naturally expected that they would come on the face. He had seen one case in which the eruption was limited to four or five vesicles situated on the neck. He believed the case to be one of small-pox as it had had all the initial symptoms. Three or four spots were the fewest number that he had ever seen in a patient, but he believed the case with two spots to be a case of small-pox. Dr. Brown had spoken of cases of small-pox eruption along with recent vaccination having a crop of vesicles round the site of the injection of the vaccine. As a matter of fact it would be expected that an increased amount of small-pox eruption would be found around areas of irritation or around points where pressure had been exerted. If there were an ulcer on the leg an enormous number of small-pox vesicles would be found to be massed together there, whereas on the rest of the body the eruption might be quite discrete. Where braces pressed, at the waist in the case of a woman, or where the garter was tied, and so on, were all points of pressure at which would be found an increased amount of eruption. As to the measurement of scars, Dr. Brown had said that most vaccination marks looked of about the area of half an inch. It was surprising how deceptive to the eye the size of a vaccination scar was. Until it came to be measured the vaccination surface would appear to be much larger than it really was.

EPIDEMIOLOGICAL SOCIETY.—A meeting of this society was held on Dec. 13th, Dr. Patrick Manson, C.M.G., F.R.S., President, in the chair.—Dr. F. W. Mott, F.R.S., read a paper on Dysentery in Asylums, a disease the prevalence of which in the London county asylums, especially that at Claybury, had led to an inquiry conducted on behalf of the Board by Dr. Durham and himself, who presented their report in May, 1900. This disease, though often designated by such names as "ulcerative colitis," "zymotic diarrhoea," &c., was, in his opinion—in which he was confirmed by Dr. Manson—simply dysentery as described by every observer since Sydenham and Willis and familiar to Indian and army surgeons to-day. It was marked by a febrile onset and inflammatory lesions of the large intestine and though it was somewhat sporadic it more often occurred in outbreaks in which the old and infirm suffered most, but no age was exempt, and the attendants and officials even were occasionally attacked, while there was absolutely no difference between cases occurring among the sane and among the insane. It presented several distinct types, from severe attacks ending fatally in a few days to mild non-febrile atypical forms which if

unrecognised tended to spread the infection. The symptoms common to all, but in very various degrees and duration, were fever, tenesmus, and loose stools with blood and slime. The initial fever might persist till death or subside after a few days whether the case progressed to recovery or death. The disease might take on a chronic or intermittent character, or blood and mucus might be absent from the stools though the typical lesions of dysentery were found after death. Pneumonia and collapse were frequent causes of death, and epileptic and paralytic patients often died in a fit. In the acute inflammatory cases there was always swelling of the mucous membrane of the whole of the large and of the lower portion of the small intestine, the engorged villi giving the surface, in the early stage, the appearance of a red Turkey carpet, followed by the ashen grey of exudation and necrosis with more or less extensive ulceration; otherwise the post-mortem phenomena of the two cases were identical and all were such as might be met with in other diseases. Leucocytes abounded in the stools, but were present in the blood in normal numbers, and were for the most part polynuclear. The bacteria were of many kinds, but unless, perhaps, certain cocci, none could be considered specific, and though some might acquire a more virulent character, the bacillus coli at any rate did not play a very important part. In chronic cases the colon might become enormously dilated, even so as to be mistaken at first sight for the stomach. Dysentery was undoubtedly an infective disease, and Dr. T. Clave Shaw's hypothesis of a neurotic origin was wholly unsupported by evidence. If it were so the disease would be met with in all asylums alike, whereas patients suffering from general paralysis were not specially prone to the disease, and while no amount of degeneration of the nerve centres could *per se* cause dysentery the splanchnic nerves in severe and fatal cases were perfectly healthy. The disease was indisputably communicable from the sick to the sound, chiefly, if not solely, through the medium of the evacuations. As with other intestinal fluxes, enteric fever, and cholera, it was impossible to avoid soiling of the clothes and bedding and of the hands of attendants, and those who knew the difficulties of dealing with insane patients and their filthy habits, would understand how hard it was to prevent the spread of the disease to other occupants of the ward. The constant transfer of patients from one asylum to another contributed to the dissemination of the infection, and it could not be denied that in some instances there had been culpable negligence and irregularities in the administration, as pouring the excreta down slop-sinks which the patients would use as hand-basins, and washing soiled linen in the baths. The irritation set up by unsound or improper food might be a possible means of inducing a recrudescence of a latent infection, but there was no evidence that it could originate the disease and the water-supply of the asylums was unimpeachable. In some the drains and sanitary arrangements had been very defective, but there had been no greater incidence of the disease in these than in others. He had no doubt that stricter observance of notification, the isolation of all cases, avoidance of overcrowding and of the transfer of patients suffering from chronic and latent forms of the disease, with enforcement of disinfection and of the precautions practised in the treatment of enteric fever, would have the effect of greatly reducing the prevalence of dysentery in asylums, if not of eradicating it altogether.—The discussion of the paper was deferred to the next meeting to be held in January.

**ÆSCULAPIAN SOCIETY OF LONDON.**—A meeting of this society was held on Dec. 20th, Dr. Arthur T. Davies, the President, being in the chair.—Dr. W. J. Gow opened a discussion on the Treatment of Placenta Prævia. He said that as soon as the diagnosis was sure treatment should be begun. With an external os of small size a tent must be introduced within the cervical canal, and later, when admissible, a hydrostatic bag. It must be remembered that foreign bodies within the cervical canal acted merely as stimuli to the uterus to contract and retract at a quicker rate than it would without that stimulus. The cervix was intolerant of forcible dilatation beyond a slight degree, and rather than so yield would split. If labour had advanced so that the cervical canal was a part of the uterine cavity and the os sufficiently large version might be attempted. If podalic version be done forceps should be at hand to apply to the after-coming head, for that method of delivery was more gentle than forcible traction made on the shoulders. He insisted that hurry in delivery should be avoided. With the end of the first stage

bleeding ceased. If, after the patient had lost much blood, there were a rapid delivery portal plethora might result fatally very soon after delivery. He thought that separation of the placenta was not only useless, but possibly harmful, by lessening the foetal blood-supply.—A general discussion followed, to which Dr. Gow replied.

**PATHOLOGICAL SOCIETY OF MANCHESTER.**—A meeting of this society was held on Dec. 11th, Mr. J. Collier, the President, being in the chair.—Dr. F. C. Moore made a communication on Hepatic Cirrhosis.—Mr. W. P. Montgomery followed with a communication on Epithelioma originating in the Deep Male Urethra. Three cases were mentioned, and in two of these the specimen and sections were shown. One case had already been reported.<sup>1</sup> In the second the growth began in the penile urethra and the complete operation with removal of the inguinal glands was carried out. In the third case (under the care of a colleague, Mr. Wright), in which the growth first affected the bulbous urethra, suprapubic cystotomy was performed.—Mr. J. B. Wolstenholme exhibited preparations from two cases of Botryomycosis in Horses. The first exhibit was one of colonies of botryomyces in the form of granules found in the pus (a case of chronic abscesses of the thigh), and the second was a section from a large fibroma of the spermatic cord after castration, showing colonies of organisms surrounded by new granulation tissue.—Dr. J. S. Bury and Dr. Moore described a Tumour from the Cervical Region of the Cord.

## Reviews and Notices of Books.

*The Principles and Practice of Operative Dentistry.* By J. S. MARSHALL, M.D. Chicago: J. B. Lippincott Co. 1901. Pp. 635, with 725 Illustrations.

THIS is an extremely well-illustrated volume. The title, however, hardly conveys a correct idea of the scope of the book. The major portion of the text deals with the anatomy and histology of the teeth and dental pathology: the minor portion with the various dental operations. The author's description of the anatomy and histology of the teeth is clear, concise, and complete, and the illustrations are excellent. There is an interesting account of the eruption of the teeth and the morbid conditions which occasionally accompany the eruption of the deciduous dentition. A chapter is devoted to the Bacteriology of the Mouth and the description of that interesting organism, the *leptothrix racemosa*, is good. The subject matter of this chapter, however, is not up to date. For example, the author states that "the mouth bacteria proper have the peculiarity that no culture medium has yet been found upon which they can be grown." This is not correct, for Mr. K. Goadby has overcome the difficulty and has published descriptions of the *bacillus maximus buccalis* and the *spirillum sputigenum*. We find, too, no reference to the *cladotrix buccalis* which Mr. Goadby has described. Good accounts are given of the pathology of the pulp and the periodontal membrane, but the classifications adopted are not satisfactory.

Throughout the book the descriptions of operative procedures are not as complete as might be expected in a volume of over 600 pages ostensibly on operative dentistry; the advice, too, is not always trustworthy. It is hardly to be credited that any modern dentist should still advocate such an unscientific instrument as the key, yet we find the author referring to this instrument in the following terms: "It is, however, a very serviceable instrument in certain cases where the crown of a molar has been broken away by caries or accident to a point beneath the gum, upon the buccal or lingual side only, while the remaining portion is strong. Such cases offer great difficulties to their extraction with the forceps, which either slip off or carry away the remaining portion of the crown, while it is often impossible to

<sup>1</sup> Medical Chronicle, June, 1901.

remove them with an elevator. The application of the turnkey to such teeth converts a difficult operation into a simple one. This is accomplished by placing the fulcrum upon the gum upon the side of the tooth which has been broken away and the claw upon the opposite side of the tooth at the margin of the gum. This permits a proper direction of the force applied and admits of an easy and natural removal of the tooth." Another example of the value of the methods advocated can be gleaned from the following reference to elevators, the pictures of which, by the way, are somewhat quaint. The author says: "In applying these instruments the grooved face is adjusted to the surface of the tooth and the blade carried downward to the alveolar process. Force is then exerted in a direction to lift the tooth from the alveolus."

The description of plastic fillings is good and contains an account of recent works on the behaviour of amalgams. We cannot, however, quite agree with all the views of the author on the uses of the various amalgams. For example, few practitioners of experience would care to assert that copper amalgam has no equal as a filling for the posterior teeth of children and that palladium amalgam has no good qualities which are not possessed in a higher degree by copper amalgam.

To sum up, this book may be considered a very fair work on dental anatomy and pathology, but a poor one on operative dentistry. The reproductions of photograms and micrograms are excellent and are certainly the most pleasing feature.

*Malaria: ihr Wesen, ihre Entstehung, und ihre Verhütung. (Nature, Origin, and Prevention of Malaria.)* By Dr. FRITZ KERSCHBAUMER, Vienna. Vienna and Leipsic: W. Braumüller. 1901. Super royal 8vo. Pp. 200. With 12 plates. Price 7 marks.

DR. KERSCHBAUMER'S book may be divided roughly into three parts, in the first of which he gives a short *résumé* of the arguments for and against the view that mosquitoes alone are responsible for the spread of malaria and a concise account of the sexual and asexual development of the parasite. In describing the changes which the plasmodium undergoes in the course of its development the author employs the terms proposed by Schaudinn and Luhe and inserts two tables of synonyms compiled by the latter which the reader will find very useful in helping to clear away some of the confusion which at present exists in this matter of nomenclature. These tables, he points out, are not given in Luhe's original article<sup>1</sup> but appear in an enlarged reprint. The second part is taken up with an account of the author's labours at San Pelagio, and the third gives the conclusions at which he has arrived as regards the best way of combating the disease. While the method advocated by Koch—viz., that of protecting the mosquitoes from malarious patients by killing the latter's parasites with quinine—may be of use in isolated communities, and the method already employed in many places of protecting people from malarious mosquitoes by means of netting, &c., is also useful, the only remedy that can be applied on a large scale, in the author's opinion, is that of exterminating the anopheles altogether. Obviously the first steps to take towards solving the problem of how best to do this were to study the life history and surroundings of the insect. San Pelagio in Rovigno (Istria), was selected as a suitable spot in which to do this, because here malaria only occurs sporadically, and it was thought that where this was the case the causes which gave rise to the disease could be isolated for observation more easily than where it was rife. At San Pelagio the anopheles larvæ were found chiefly in shallow pools of clear water which were rich in zooplankton, while foul water was fatal to them. In this connexion it is interesting to note that culex larvæ thrived

in flasks of pond water which were kept sweet by the introduction of fresh eucalyptus leaves, while in the control flasks the larvæ died apparently from fouling of the water. The anopheles larvæ are ferocious little animals and in the culex aquaria they play the part of a pike in a carp pond. The author has seen a hungry one bite a culex larva in two, and they even indulge in cannibalistic practices. While the larvæ usually keep to the surface of the water they invariably descend to the bottom of the pond to change their skins, but they appear to be unable to do this where the water is more than one metre in depth. If a pool in which they are living be artificially deepened to this extent the larvæ die. On this observation the author founds his proposal for the destruction of the mosquitoes, which is to flood their breeding-places to the depth of more than one metre. In several places (e.g., Mantua and Mexico) malaria appeared when the lakes surrounding these cities were drained. In the case of the former it diminished again when weirs were built to keep the swamps flooded. In some localities this method will doubtless prove successful, though obviously its sphere of usefulness will be limited by engineering and economic considerations as much as other prophylactic measures are by the difficulties peculiar to them. The author's investigations throw a good deal of light on the development of certain species of mosquitoes in a temperate climate, and we shall be glad to see the results of further researches which he is about to make in this direction.

*Clinical Pathology and Practical Morbid Histology.* By T. STRANGEWAYS PIGG, M.A., Demonstrator of Pathology in the University of Cambridge. Second edition. London: Strangeways and Sons. 1901. Pp. 107. Price 5s.

WE are glad to welcome a second edition of this excellent little book. The methods given are carefully selected, clearly described, and especially suitable for use in a clinical laboratory. It is necessarily in great part a book of receipts—it is a laboratory handbook pure and simple—and no attempt is made to explain the methods, though there is a departure from this treatment of the subject in the account of the blood-cells and in the excellent scheme for making and reporting upon a blood examination. The only method given for the direct estimation of hæmoglobin is that of von Fleischel, but possibly there are sound reasons for selecting this one method. It is perhaps to be hypercritical, but as the surgical operations required for obtaining blood for bacteriological examination are so carefully described it might be as well to mention the removal of the constricting bandage from the patient's arm (par. 6, p. 30). It is doubtful whether anyone qualified to obtain blood by this method would require such elaborate directions. Would it not also be better to place Operation 6 on page 46 between Operations 4 and 5? Neisser's method for staining diphtheria bacilli is stated in its original form but most workers find the times given rather short. We would venture to think that there are better methods for removing the serum from the collecting pipette in making the Widal-Grünbaum test than that given, as, in our experience, it is the exception rather than the rule to find that the serum can be blown out as described. The figures are, with the exception of the excellent blood plates, somewhat rough, but they serve their purposes. The blank pages should prove very useful, as also would an index, which is at present wanting. The book, in short, is an excellent specimen of what a laboratory handbook should be and will certainly be of great service.

#### LIBRARY TABLE.

*A Manual of Bacteriology.* By HERRBERT W. WILLIAMS, M.D., Professor of Pathology and Bacteriology, Medical Department, University of Buffalo. Second edition, revised and enlarged. London: Rebman, Limited. 1901. Pp. 290

<sup>1</sup> Centralblatt für Bakteriologie, 1900, Band xxvii., p. 367.

Price 7s. 6d. net.—A few years ago text-books on bacteriology were few and the student was dependent to a large extent upon lectures for his knowledge of the subject. Now there is a constant stream of manuals, most of them written with an eye to the medical man or the medical student. The present work is of this class and "endeavours to describe the laboratory technique which the beginner must follow and at the same time to give a concise summary of the facts in bacteriology most important to the physician." The second endeavour is more successfully accomplished than the first and the second part of the book is better than the first. Technique can only be learnt in a laboratory and though the principles underlying technical methods may reasonably be dealt with in such a work as the present the actual instruction required to carry out any method can only be given in the guise of a laboratory handbook where each step is set out in sequence. While there are no obvious errors other than those of omission in the technical operations detailed, in very few cases would the student by simply reading the first part of this book be able to get successful results. The author, too, here seems a little uncertain of his readers, as it is difficult to believe that it is necessary to explain that spirillum is the singular of spirilla or that material for microscopic examination "is usually placed upon thin slips of glass called cover-glasses." It is recommended that material for work should be obtained so far as possible from nature rather than from laboratory cultures, and this is good advice. The second part of the book is decidedly good, taking into consideration the necessity of conciseness, and especially the chapter on Bacteria in Disease, though, owing to the compression, probably the student would not get so much out of the chapter as the author has put into it. It is very difficult to treat of immunity in 10 pages of text, especially when vaccination and the production of antitoxic serum are also described there. The needs of the practitioner are consulted by two chapters on Disinfectants, and the Sterilisation of Instruments, Dressings, &c. The subjects are treated somewhat at length and in a practical manner by Dr. Carpenter and Dr. Chauncey P. Smith respectively. Part III. gives a short account of some of the commoner non-pathogenic bacteria, and Part IV. is devoted to a description of the pathogenic microbes of the most common occurrence and clinical importance. Throughout the descriptions the facts of value to the medical man are kept prominent. On the whole the aims of the author seem to be successfully accomplished. The illustrations are in great part borrowed from the excellent works of Fraenkel and Pfeiffer and Günther. They are well reproduced, and the printing, paper, and binding are all satisfactory. The book will be useful to all medical men who desire a short concise account of bacteriology as it affects clinical work.

*The End of an Epoch.* By A. LINCOLN GREEN. Edinburgh and London: William Blackwood and Sons. 1901. Pp. 391. Price 6s.—We congratulate Mr. Lincoln Green on a powerful and in many ways original story. Incidentally we may mention that he might have spared us the harmonium in Durham Cathedral. A "positive" organ would have taken up no more room and would not have been so incongruous. But to go on to the story, which is by no means a cheerful one. Adam Gordon, a young bacteriologist, becomes acquainted with a direful old man, one Professor Falk, who after long research has evolved a cross-bred microbe called "B. paradoxus." It is quite new and sporulates with exceeding vigour, so that mankind is practically helpless against it. However, there is an antitoxin for it; the bacillus does not affect people over 70 years of age, and its spores are inactive at a temperature of 38° F. We will not be so unkind as to give away Mr. Lincoln Green's plot; suffice it to say that there is nothing theoretically impossible in his story. The book is well worth reading,

although we should say that the author is a young writer, for he has not altogether surmounted the difficulties of writing a long narrative in the first person. But although he is not a Defoe he has descriptive powers. Witness the incident of the starving pack of hounds and the horse in St. Paul's Churchyard. Though a novel of the pathological order the writer does not go into unpleasant details, as is the custom of some authors. We look forward to Mr. Lincoln Green's next book.

*The First Men in the Moon.* By H. C. WELLS. London: George Newnes, Limited. 1901. Pp. 342. Price 6s.—Mr. Wells, in his latest fantasy, follows in the steps of other writers of imaginary journeys. Lucian, Ariosto, Poe, and Baron Munchausen all wrote about daring travellers who arrived in the moon, while Jules Verne wrote an amazingly convincing account of how to get there. That his dauntless three did not succeed in landing was due to influences quite beyond their power to rectify. Cavor, who is Mr. Wells's protagonist, had a simple theory which he converted into fact. His argument was that if, as everyone knows is the fact, there are some substances which are impervious to light rays or heat rays or electrical rays, so, also, there may be a substance which is impervious to gravitation. He experiments until he manufactures such a substance and then constructs a sphere, or rather a polyhedron, which is covered with plates of the substance in question called "Cavorite." These plates can be drawn up and down like blinds, so that when they are drawn up that surface of the sphere which is uncovered is attracted by gravitation. When all the plates are down gravitation is entirely cut off. Cavor and his companion start in this manner by cutting off all gravitation, and when they get near the moon they draw up one of the plates on the side of the sphere nearest the moon. The attraction of this body then pulls them into it. For their adventures in the moon we must refer our readers to the book itself. Suffice it to say that the polity of the Selenites is division of labour pushed to its utmost extent. The book is one to read and to enjoy.

*By-laws as to House Drainage and Sanitary Fittings Made by the London County Council.* Annotated by GERARD J. G. JENSEN and Another. London: Sanitary Publishing Company, Limited. 1901. Pp. 139. Price 3s. 6d.—The new drainage by-laws of the London County Council came into force on June 14th last. The changes thereby involved are of the greatest importance to architects, sanitary inspectors, builders, and others officially or otherwise interested in house-property in the metropolis. The object of the present work is to explain the by-laws in detail and thereby to assist those who are affected by them to a clearer conception of the various requirements embodied therein and to avoid unintentional infringement. The work has been prepared by Mr. Gerard J. G. Jensen, C.E., in conjunction with a gentleman holding a high official position whose name is withheld for the present. The information embodied in the work will render it useful to every householder. The annotations are clearly written and explain the by-laws in such a way that no one after reading them ought to be betrayed into unintentional infringement of the regulations of the London County Council. A block plan map of the administrative county of London and upwards of 100 illustrations serve to make the work easy to follow.

*A Versailles Christmas Tide.* By MARY STUART BOYD. London: Chatto and Windus. 1901. Price 6s. Pp. 81.—A very pretty little story, although it does deal with scarlet fever, with equally charming pictures by A. S. Boyd.

GLoucester INFIRMARY.—At a special general meeting of the governors of the Gloucester Infirmary it was decided to make several structural alterations in the institution at an estimated cost of £10,000.

LONDON: SATURDAY, DECEMBER 28, 1901.

## THE ANNUS MEDICUS 1901.

### MEDICINE AND THERAPEUTICS.

#### *The British Congress on Tuberculosis.*

THE chief medical event of the year was undoubtedly the meeting of the British Congress on Tuberculosis. It was instrumental in bringing together a large number of workers in the field of preventive medicine both in this country and abroad, and this act was attended with a useful exchange of ideas and with a quickening of the public conscience in the matter of State medicine generally and of the prevention of tuberculosis in general. The great sensation of the Congress was undoubtedly the address of Professor KOCH, in which he threw doubt upon the communicability of tuberculosis from animals to man. This statement brought forth replies from several noted observers, such as Lord LISTER, Professor BANG, Professor NOCARD, Professor G. SIMS WOODHEAD, and Professor J. MCFARDEAN, and it was evident that in the opinion of comparative pathologists there were at least other sides to the question. As we have previously pointed out, one of the objects of a scientific congress is to try to obtain legislation on matters which relate to the public weal; the discussion which ensued consequent on Professor KOCH's paper aroused such widespread interest that the Government speedily appointed a Royal Commission with full powers to investigate the comparative phenomena of tuberculosis in man and the lower animals. The constitution of the Commission is such as to guarantee that everything that experience, energy, and scientific knowledge can provide will be brought to bear in the elucidation of many of the obscure points which complicate the problems of tuberculosis. Professor BROUARDEL delivered an address which was full of useful information and of encouragement with regard to the utility of preventive measures. He attributed the decline of pulmonary tuberculosis in this country largely to the better housing of the poor and to the generally improved condition of the labouring classes. In the various sections into which the work of the Congress was divided many papers of great interest were read and important discussions took place. A marked and satisfactory feature of the Congress was the number of foreigners who took part in the proceedings. The museum which was established in connexion with the meeting reflected the greatest credit on those responsible for its existence.

#### *Bovine and Human Tuberculosis.*

In connexion with Professor KOCH's communication to which we have above referred a paper which was read by Dr. M. P. RAVENEL was of particular interest. His experiments and the evidence which he had collected went to prove that the tubercle bacillus from bovine sources had in culture fairly constant and persistent peculiarities of growth and morphology by which it might tentatively be differentiated from that ordinarily found in man. Further, Dr. RAVENEL was of opinion that it was a fair assumption from the evidence at hand, and in the absence of evidence to the contrary, that the bovine tubercle bacillus had a high degree of pathogenic power for man also, which was especially manifest in the early years of life.

#### *The Treatment of Pulmonary Tuberculosis.*

Many methods of treating pulmonary tuberculosis have been proposed, but none of them have been generally adopted. Successful results have, of course, been claimed by the observers who have introduced such therapeutic measures, but when subjected to skilled supervision or tried by equally competent physicians the progress of the cases has not been shown to excel, or generally even to equal, that exhibited by the methods of treatment already in existence. The "hygienic" or "open-air" treatment is being largely adopted and sanatoriums have been or are being established in districts of the country which are deemed suitable sites for them. The results continue to be satisfactory, and various schemes have been proposed for the extension of the treatment for those who are unable to pay the fees charged by the private establishments.

#### *The Royal Commission on Arsenical Poisoning.*

The decision of the members of the Royal Commission on Arsenical Poisoning to report their proceedings from time to time and to summarise in a series of reports the conclusions at which they have arrived is a good one and will be received with general satisfaction. The first report was published about the middle of the year and related to arsenic in beer. The evidence afforded by the recent epidemic in the north of England was fully considered and the Commission had no difficulty in arriving at the conclusions: (1) that the cases of sickness and death reported during the epidemic were attributable to poisoning by arsenic, and (2) that such exceptional sickness and death were due to arsenic in beer. The members of the Commission have yet to consider the apparent ubiquity of arsenic, and by what safeguards the introduction of arsenic into food and many other things besides beer can be prevented; they have also to hear evidence on other matters closely connected with the subject.

#### *The Prevention of Typhoid Fever.*

The preventive inoculation against typhoid fever has not fulfilled the hopes that were at one time attached to it. The production of artificial immunity has undergone a very severe trial amongst the troops in South Africa. The general opinion of the medical officers seems to be that a certain amount of protection is afforded by the injections, but that the immunity so conferred is not of long duration. Dr. H. H. TOOTH, in a paper read before the Clinical Society of London on his personal experiences of enteric fever among the troops, spoke favourably of the method, and was of opinion that the disease took a milder and more benign course in the inoculated than it did in the non-inoculated. Inoculation cannot, however, be said to have had a fair trial, and until the figures for the whole army are published no definite conclusion can be arrived at as to its value in protecting from the disease and its effect on the mortality of those attacked.

#### *The Treatment of Diphtheria.*

The statistics published from time to time in this and other countries continue to bear strong witness to the value of the antitoxin treatment. The reports go to show that the antitoxin is harmless and should therefore be used in all cases of doubtful disease of the throat when the affection is severe without waiting for bacteriological confirmation. It has been clearly proved that the earlier the injection is given the better is the result. In those cases in which the antitoxin is given on the first or the second day of the illness the mortality is far below that which occurs when its administration is postponed until a later period.

#### *Small-pox.*

The outbreak of small-pox in London which has continued since the end of July shows no certain signs of decrease, and according to the experience gained by other epidemics the cases may be expected to increase in number. One

of the most prominent lessons afforded by the present outbreak is the difficulties which have been experienced in diagnosis. We have several times referred to this point in our columns. The difficulties arise from two main causes, (1) the modification of the eruption due to the effects of previous vaccination, the efficacy of which has begun to wane owing to lapse of time, and (2) the want of experience in many practitioners, who, thanks to the general adoption of vaccination, especially amongst the educated classes, have had but little experience in the disease. The present laws relating to vaccination are only "experimental," and it will be interesting to see how the more recent outbreaks will affect legislators when the question is again discussed in Parliament.

#### *Scarlet Fever.*

Scarlet fever has been very prevalent during the later months of the year. The report of the medical officer of the London County Council issued in November is of great interest as proving how the disease can be spread by milk. Scarlet fever was shown to have existed on a certain farm whence milk was supplied to the districts where scarlet fever had broken out. An important point brought out in the report was that the middleman had no records which would enable him to give information as to how the milk from his several farms had been distributed among the local vendors. Some better machinery for detecting and excluding infective milk from London is obviously needed, and this, it may be hoped, will at no distant date be provided.

#### *Rheumatic Fever.*

The supposition that rheumatic fever is due to a pathogenic organism is gradually being substantiated; as a result, in most of the modern text-books this disease no longer finds a place amongst "diseases of the joints," but amongst the specific fevers. Dr. F. J. POYNTON and Dr. ALEXANDER PAINE have continued their researches upon rheumatic fever. They have demonstrated the diplococcus in rheumatic nodules and have isolated the organism from the nodule in pure culture. Further, intravenous inoculation of this culture produced valvulitis, pericarditis, and polyarthritis in a rabbit, and, finally, the diplococcus was isolated from the exudation from the joint of this rabbit.

#### *Sporadic Cerebro-Spinal Meningitis.*

Dr. WILLIAM HUNTER (assistant bacteriologist to the London Hospital) and Mr. A. W. NUTHALL have published some interesting results on the bacteriology of sporadic cerebro-spinal meningitis. In all the cases of meningitis which they examined a diplococcus was isolated from the cerebro-spinal fluid. This diplococcus was found to have the same morphological and biological characteristics as Professor WEICHSELBAUM's diplococcus intracellularis meningitidis. The clinical picture and the pathological changes found in the cases of Dr. HUNTER and Mr. NUTHALL corresponded with those that are met with in so-called "posterior basal meningitis." These observers, therefore, came to the important conclusion that in all probability "posterior basal meningitis" is simply a sporadic manifestation of cerebro-spinal meningitis and is produced by the same micro-organism.

#### *The Lectures of the Year.*

The Baillie lectures at St. George's Hospital were delivered by Dr. W. HOWSHIP DICKINSON, who chose for his subject, "Considerations Touching the Pathology and Relations of Diabetes." Many interesting points were referred to, especially in regard to the relation of the nervous system to diabetes. In speaking of treatment Dr. DICKINSON threw much doubt on the efficacy of opium and its derivatives in checking the disease. Dr. J. MITCHELL BRUCE delivered the Lettsomian lectures before the Medical Society of London on Diseases and Disorders of the Heart and Arteries in Middle and Advanced Life. He drew attention to the many forces

that threaten the heart and arteries which are peculiar to that period of life and brought forward many interesting points in reference to etiology and treatment. The Croonian lectures at the Royal College of Physicians of London were delivered by Dr. W. D. HALLIBURTON. The subject was an abstruse one: "The Chemical Side of Nervous Activity." The lecturer handled it, however, in a most able manner and his observations on the cerebro-spinal fluid form a valuable source for reference and study. The Goulstonian lectures at the Royal College of Physicians of London were delivered by Dr. HENRY HEAD. The subject selected was "Certain Mental Changes that accompany Visceral Disease." It was shown that the presence of pain of the reflected visceral type tends to be associated with a mental state, containing amongst other conditions a sense of ill-being and a causeless suspicion. The Cavendish lecture was delivered before the West London Medico-Chirurgical Society by Sir RICHARD DOUGLAS POWELL who suggested many lines of thought with regard to "acute cardiac failure." The Bradshaw lecture at the Royal College of Physicians of London was in the hands of Dr. JUDSON S. BURY who selected as his theme "Prognosis in Relation to Disease of the Nervous System."

#### *The British Medical Association.*

The British Medical Association met at Cheltenham, and many interesting papers were forthcoming in the Medical, Pathological, and Therapeutical Sections. The address in medicine was undertaken by Dr. J. F. GOODHART, who gave an eloquent discourse on the difficulties encountered in the daily practice of medicine. Amongst the most interesting discussions were those on Rheumatism (introduced by Dr. ARCHIBALD GARROD), on the Power of Alcohol to Produce Peripheral Neuritis (introduced by Dr. E. S. REYNOLDS), and on the Pathology of Pneumococcal Infection (introduced by Mr. A. G. R. FOULERTON).

#### *New Publications.*

The publication of the "Twentieth Century Practice" is now complete and forms a vast work representing an excellent summary of our present knowledge of medical science. The whole work has been carried out in a manner worthy of the highest praise. The "Encyclopædia Medica" has reached the eighth volume and Dr. W. H. ALLCHIN'S "Manual of Medicine" the third volume. An elaborate "Text-book of Medicine" edited by Dr. G. A. GIBSON has appeared and new editions of many well-known text-books have also been published. Reviews of these works have already appeared in the columns of THE LANCET.

#### SURGERY.

Few surgeons will be found to question that in the past year, as in several that have preceded it, abdominal surgery has held the chief place, and the explanation of this very evident fact is to be found partly in the large number of organs contained in that cavity, and partly because we can shut off the general cavity of the peritoneum by careful packing with gauze, so that we need have but little fear of infecting the peritoneum generally. Much has been done, yet doubtlessly much more remains to be done.

#### *Bullet-wounds of the Stomach.*

The assassination of President MCKINLEY directed the attention both of the profession and of the public to the subject of bullet-wounds of the stomach. The marvellous results of bullet-wounds inflicted by the Mauser rifle had much impressed every one. Bullets had in some cases certainly traversed the abdomen and had undoubtedly perforated some of its hollow viscera, and yet recovery ensued without any operative interference. It was but natural to imagine that a similar happy ending might be encountered in persons wounded by pistol-bullets in civil life, but the conditions are very different. The nickel-coated Mauser bullet

bores a small smooth hole through an organ—so small and so smooth that in many cases no extravasation takes place, and the wounds heal practically by first intention. Far otherwise is it with wounds inflicted with a revolver-bullet; these are not only often of greater diameter, but they have no casing, and therefore are much more liable to be altered in shape in their passage through the tissues. These reasons quite suffice to account for the far greater damage they inflict; therefore it cannot be expected that the wounds will heal easily, as their edges are bruised; so that it comes to pass that the greatest surgical skill in adjusting and suturing the edges of the wound may avail [nothing, for the damaged tissues may make no effort at repair. We have reported several cases in which so-called toy-pistols have inflicted serious injuries; the only way to put a stop to the sale of these harmful and useless weapons is to make the vendors of them responsible.

#### *Extirpation of the Stomach.*

Only three or four years ago total extirpation of the stomach was considered, and rightly so, as a most marvellous achievement; yet the operation has been so many times repeated now that it has lost no small degree of the distinction it once possessed. We have recorded a successful case of total gastric extirpation which was performed by Dr. A. VON BARDELEBEN of Westphalia, in which the patient markedly increased in weight after the operation. Up to the present 11 or 12 cases have been reported in which the whole of the organ with small portions of the œsophagus and duodenum have been removed, and very many more in which nearly the whole viscus has been excised.

#### *Gastric Ulcer.*

The surgical treatment of gastric ulcer, especially when complicated with hæmatemesis, is steadily advancing. Perhaps at first, when the idea of surgical intervention in ulcer of the stomach arose, there was a little tendency to unnecessary interference, for every one will acknowledge that many gastric ulcers do heal spontaneously or after medicinal treatment and dieting. Perhaps the most important contribution to our knowledge on this subject was an address delivered by Professor A. W. MAYO ROBSON before the Edinburgh Medico-Chirurgical Society; in this he pointed out the great risk of fatal hæmorrhage in gastric ulcer and showed the satisfactory results of timely surgical treatment. The value of operation for chronic gastric ulcer was further emphasised by the same surgeon in an address delivered before the American Surgical Association. Mr. C. R. B. KEETLEY also has recorded several cases showing the benefit of operation in hæmatemesis. When an ulcer of the stomach perforates into the peritoneal cavity the general peritonitis which arises is before operation often indistinguishable from peritonitis arising from appendicitis or other causes, and even when a definite diagnosis cannot be made there need be no doubt as to the advisability of a laparotomy. In the diagnosis of perforative peritonitis too much stress is still laid on absence of the liver dulness, for this is a sign which is very variable. The liver dulness may be present although perforation has occurred, and, on the other hand, it may be absent without any perforation of any viscus. We have published in THE LANCET during the year many papers describing the surgical treatment of these cases of perforative peritonitis and the results are in no small proportion very gratifying. As to the correct treatment of the peritoneal cavity after the perforation has been sutured there is by no means unanimity. Many surgeons still flush out the abdomen with large quantities of sterilised water, while others content themselves with sponging. We do not at the present time possess sufficient data to come to a decision on this important point, for recoveries occur after the employment of each method. On the whole it may be said that flushing the peritoneal cavity

is now not so frequently used as it was a few years ago. A case of great interest was recorded by Mr. A. A. BOWLBY and Mr. J. F. STEEDMAN; a young woman had a gastric ulcer which perforated and Mr. BOWLBY opened the abdomen and sutured the perforation. The patient did well for three weeks, when symptoms of intestinal obstruction arose; these were found on laparotomy to be due to a volvulus of the small intestine caused by its fixation in Douglas's pouch. The second operation was followed by complete recovery.

#### *Hour-glass Stomach.*

A paper on Hour-glass Contraction of the Stomach by Mr. B. G. A. MOYNIHAN deserves mention; in it is contained a table of 36 cases recorded in medical literature and notes of six cases in which he had himself operated. It is customary to consider a large proportion of these cases to be of congenital origin, but Mr. MOYNIHAN advances good reasons for doubting if any truly congenital cases exist. Several operative procedures can be employed for the treatment of hour-glass contraction, but no single operation can be said to be best in all cases. The simplest method is gastropasty—that is, longitudinal incision and transverse suture—but this is only suited to cases in which the ulcerative process has ceased and there is no pyloric obstruction.

#### *Resection of the Bowel.*

The danger of operating on diabetic patients has been generally acknowledged, but Mr. A. E. J. BARKER has reported a case in which he excised successfully a carcinoma of the large intestine in a woman, 58 years of age, whose urine contained over 6 per cent. of sugar. With aseptic surgery, however, much may be done that was formerly impossible, though it will probably always be found that diabetic persons will not prove very favourable subjects for operation. Mr. BARKER has made another contribution on intestinal surgery: he has removed five and a half feet of the small intestine from an old woman, 76 years of age, and the patient recovered. This is a large amount of bowel to excise, but it has been surpassed in a case in which RUGGI removed more than 10 feet of bowel from a boy, eight years old; but when we consider the length of intestine removed by Mr. BARKER and the age of the patient we cannot fail to recognise the striking character of the case.

#### *Intestinal Anastomosis.*

The methods which have been devised for the anastomosis of bowel are very numerous; in all more than 200 different devices have been described, but it may safely be said that not more than 20 of these survive. Mr. H. LITTLEWOOD has introduced a method of intestinal suture by means of a continuous catgut stitch, with excision of the mucous membrane. This excision is intended to prevent the tendency, sometimes observed, to spontaneous closure of the anastomotic opening. Mr. LITTLEWOOD has performed seven or eight gastro-enterostomies and three colectomies with it, and it certainly seems worthy of a trial. The importance of counting the number of instruments and sponges used in abdominal operations was very strikingly shown in a case reported by Mr. E. H. ELLISON. He found in a patient who complained of severe abdominal pain that a part of a pair of artery forceps was projecting from a small opening in the abdominal wall about three inches below and to the left of the umbilicus. As the patient declined any cutting operation, and as it was impossible to remove the forceps without, the blades were broken off and removed and later one handle was got away. The original abdominal section was performed eight and a half years previously and for all that length of time the forceps had been lying in the abdomen.

#### *Wounds of the Heart.*

Little has been done in the surgery of the vascular system, but a few important operations are well worthy to be referred

to. For rupture of the heart and for incised or punctured wounds of the same organ there is very little chance of recovery apart from operation. Dr. L. L. HILL has contributed a valuable paper pointing out the importance of prompt surgical interference in these injuries. In 45 cases in which the heart was ruptured by injury all died, one patient surviving 14 hours. Of patients operated on for heart wounds 41 per cent. recovered, as against 10 per cent. on whom no operation was performed. The sutures applied to the heart substance should be close together and should not involve the endocardium. They should be passed and tied during diastole and silk is the best material. Dr. HILL gave notes of two cases of heart injury; in one a needle which had penetrated the heart of a little girl was safely removed and in the other a young man was stabbed in the left fourth intercostal space. The blood was let out by enlarging the wound in the pericardium. The great obstacle in the way of much cardiac surgery is that the patients generally expire before any surgical aid can be obtained.

#### *Suture of Arteries.*

It has until comparatively recently been imagined that a wound in an artery could only be closed by double ligation of the vessel. Attempts, however, have been made to maintain the lumen of the artery, and in a few cases success has followed. The first successful suture of a vessel was performed in 1762. A very brilliant arterial suture was performed by Dr. A. E. HALSTED of Chicago. Dr. HALSTED, in removing a recurrent carcinomatous growth from the axilla, cut into the axillary artery so that it was severed for about two-thirds of its circumference. As at the first operation practically all the branches of the artery, with the exception of the circumflex, had been cut, there was very little chance of a collateral circulation being established. Therefore an attempt to save the artery was made. The circulation was controlled by pressure of the left index finger, and four interrupted catgut sutures were passed through the two outer coats of the vessel and tied. No hæmorrhage followed when the pressure on the artery was removed. Further support to the vessel was given by suturing longitudinally the peri-vascular connective tissue. The patient made a complete recovery and the radial pulse was undisturbed from the very beginning.

#### *Intra-thoracic Aneurysms.*

Intra-thoracic aneurysms have been treated surgically by many methods, but at the present day most of these have been deservedly given up. The injection of a solution of gelatin has been followed by marked improvement in a fair number of cases, and the treatment is undoubtedly well deserving of attention. Unfortunately, of three cases recently treated in London by this method two terminated fatally with symptoms resembling those of tetanus. It is, of course, possible that the injections, though carefully prepared, had become infected with the bacillus tetani, but it is by far more likely that the spasms were the result of chemical products contained in the gelatin.

#### *Actinomycosis.*

Actinomycosis has in this country hardly received the amount of notice that it deserves, for the disease is by no means extremely rare, and it is probable that many cases are unrecognised. Mr. R. J. GODLEE has recorded a series of 15 cases of the disease which he has met with. Generally the abscesses to which the fungus gives rise are imagined to be ordinary abscesses, though a keen eye may detect the little yellow granules. It would be well to examine more frequently the pus evacuated from an abscess, and it is not improbable that the actinomyces would be more frequently encountered.

#### *Enlarged Prostate.*

The diseases of the prostate have lately received much

attention, and several papers bearing on this important subject have been published. Two clinical lectures by Mr. P. J. FREYER have appeared and put very clearly the present position of our knowledge of the treatment of enlarged prostate, and Mr. DAVID WALLACE has also spoken on the same subject. Castration and vasectomy hardly occupy the place in the estimation of surgeons which was once accorded to them. In many cases a large mass of the gland may be enucleated, and this appears to be a very satisfactory operation.

#### *Renal Tension.*

The surgical treatment of acute nephritis was discussed in the surgical section at the Cheltenham meeting of the British Medical Association, and Mr. REGINALD HARRISON opened the discussion. He showed that in many cases the increase of tension in itself was harmful. In such cases a small incision, or even punctures, may suffice to reduce the tension in the organ. Though we must not expect too much from this novel procedure, yet we may not unreasonably hope that it will give us some assistance in dealing with a condition which is practically beyond the measures hitherto adopted for its relief.

#### OBSTETRICS AND GYNÆCOLOGY.

The past year has not witnessed any notable change either in the theory or in the practice of obstetric medicine and gynæcology. A great deal of good work is being done and the output of literature shows no decline either in quantity or quality.

#### *Cæsarean Section.*

Amongst the more interesting of the papers which have appeared in THE LANCET are the records of a number of cases of Cæsarean section. In THE LANCET of Jan. 19th, p. 158, Professor W. J. SINCLAIR reported a Series of Ten Successful Cases of Cæsarean Section with recovery of all the mothers and children. In three of the cases the uterus was removed, but in the remainder the conservative operation was performed. In the first five cases drainage was resorted to, but not in any of the later cases. An elastic tube was passed round the uterus so as to be available if required to produce compression of the vessels, and in all the cases the uterus was brought outside the abdomen before the incision into it was made. Professor SINCLAIR does not approve of the fundal incision recommended by FRITSCH, mainly because of the extreme likelihood of the intestines and omentum becoming adherent to the line of suture, and of the danger that the fundus of the uterus may adhere to the parietal peritoneum before involution is complete and cause pain by dragging upon the area of adhesion situated high up in the abdominal cavity. A case of Cæsarean Section and Complete Removal of the Uterus in the Eighth Month of Pregnancy for cancer of the cervix was reported by Dr. THOMAS OLIVER and Mr. R. MORISON. Five months later the mother was well without any sign of recurrence and the child was flourishing. In THE LANCET of June 8th, p. 1604, Dr. G. E. HERMAN recorded Two Cases of Cæsarean Section, one performed on account of the presence of a flattened rickety pelvis with a true conjugate diameter measuring two and a half inches, and the other performed on a patient who had a fibroid tumour in the pelvic cavity obstructing delivery. Both mothers recovered and one child lived, these two cases bringing the total number of Cæsarean sections performed by Dr. HERMAN at the London Hospital up to 13. Seven of the mothers recovered and six died. In all the six fatal cases the operation was not performed until the patients had been for a long time in labour.

#### *Physiology of Menstruation.*

The interesting question of the Physiological Phenomena preceding or accompanying Menstruation, together with Notes on the Normal Temperature of Women, was discussed by Dr. HELEN MACMURCHY in THE LANCET of

Oct. 5th, p. 909. One of the most important of the Clinical Lectures published in our columns was that delivered by Dr. WILLIAM S. PLAYFAIR upon Chronic Invalidism in Women.

#### *Opothrapy.*

Opothrapy was the subject of a short communication by Dr. JOHN PHILLIPS and was discussed in detail at a meeting of the Philadelphia Obstetrical Society. Dr. PHILLIPS has obtained good results from the administration of thyroid extract in cases of amenorrhœa associated with obesity and myxœdema, and from ovarian extract in cases of the induced and natural menopause. The majority of the speakers who took part in the discussion at Philadelphia had not had any very striking results from the use of the various extracts in gynæcological conditions and the general opinion appeared to be that at the present time there was very little trustworthy evidence of their real value. In Professor E. A. SCHÄFER's laboratory at Edinburgh experiments have been carried out which show that the medullary substance of the suprarenal capsule of the ox or sheep has the power of inducing vigorous contractions in both the pregnant and non-pregnant uterus. The extract may be given by the mouth or used as an intra-uterine injection. Professor SCHÄFER has found that an intravenous injection of a dose of a decoction equal to five grains of the dried extract will rapidly re-establish the action of the heart even after the circulation appears to have ceased, and suggests its use in cases of post-partum hæmorrhage.

#### *Eclampsia.*

The treatment of eclampsia continues to excite a great deal of interest. It formed the subject of a discussion at the German Gynæcological Congress at Giessen and was considered in a paper read before the Obstetrical Society of London by Dr. E. W. HEY GROVES, who gave details of two cases treated by saline infusions, reviewed the whole subject, and warmly recommended this mode of treatment. A paper by Dr. R. JARDINE, who is a strong advocate of the value of saline infusions, entitled "The Treatment of Puerperal Eclampsia by Saline Diuretic Infusions," was published in THE LANCET of June 15th, p. 1682. The various papers read upon this subject at Giessen were remarkable chiefly for the large amount of experimental work brought forward. It is almost impossible at the present time to summarise the opinions of the different speakers, so widely divergent are their views upon many important points. Upon the whole, the value of saline infusions as an auxiliary mode of treatment was recognised by all those who had had any practical experience of this mode of treatment. No definite conclusions, however, were arrived at upon such important questions as the administration of morphia, the performance of *accouchement forcé*, or the practice of Cæsarean section. A great deal of evidence was adduced both for and against the toxic theory of the causation of the disease.

#### *Fibroid Tumours.*

In view of the great advances made in the operative treatment of fibroid tumours of the uterus the treatment of cases of pregnancy complicated by the presence of these tumours has undergone a certain amount of change. This subject was considered in a paper upon Fibroid Tumours complicating Labour and Pregnancy, read before the Obstetrical Society of London by Dr. ARCHIBALD DONALD who arrived at the following conclusions:—

1. In the great majority of instances in which fibro-myomata of the uterus and pregnancy co-exist the course of the pregnancy and of the subsequent labour is not seriously influenced by the tumour; but in a small proportion of cases the patient's life and the life of the child are seriously endangered.
2. When pregnancy is found to be complicated by fibroid tumour it is best to allow the pregnancy to go to term, as long as the mother's health is not seriously endangered.
3. If at the onset of labour, or shortly before, it seems certain that the tumour will cause obstruction to the birth of the child, Cæsarean section, followed by hysterectomy, should be performed.
4. In cases in which the health of the mother makes it necessary to

interfere in the earlier months abdominal section should be performed and an attempt made to enucleate the tumour.

5. If under these circumstances myomectomy is found to be too dangerous, hysterectomy should be performed.

In the discussion that followed most of the speakers expressed the view that a very small number of cases of fibroid tumours complicated by pregnancy required operative measures, and that this was especially the case with subserous fibroid tumours of the uterus. The same question was discussed by Mr. J. BLAND-SUTTON in a series of three lectures on the Surgery of Pregnancy and Labour complicated with Tumours, published in THE LANCET of Feb. 9th (p. 382), 16th (p. 452), and 23rd (p. 529), while at the British Medical Association meeting at Cheltenham Dr. WILLIAM DUNCAN opened a discussion upon When and How to Operate upon Fibroid Tumours.

#### *Leukæmia and Pregnancy.*

At the October meeting of the Obstetrical Society Dr. HERMAN contributed a paper on Leukæmia and Pregnancy, reporting a case of his own and 12 other cases which he had collected from the literature of the subject. From eight of these cases he drew the following conclusions:—

- (1) The presence of an enlarged spleen and liver caused patients with leukæmia to suffer more from the abdominal distension of pregnancy than healthy women; (2) the symptoms of leukæmia were aggravated during pregnancy; (3) in pregnancy with leukæmia there was a great tendency to abortion or premature labour; (4) death sometimes quickly followed the termination of pregnancy with leukæmia; and (5) if the patient survived the termination of pregnancy great improvement took place. Dr. Herman therefore recommended in pregnancy with leukæmia the induction of premature labour or abortion.

#### *Puerperal Fever, Cancer of the Uterus, and the Birth-rate.*

In his presidential address in the section of Obstetrics and Gynæcology at the meeting of the British Medical Association at Cheltenham Professor J. W. BYERS considered the important questions of the Mortality from Puerperal Fever, Cancer of the Uterus, and the Falling Birth-rate. He called attention to the astonishing fact that the death-rate from puerperal fever, which in the years 1847-56 was 1.8 per 1000 in England and Wales, was 2.46 per 1000 in the years 1886-95, and showed that the death-rate from the same cause in Scotland and Ireland was practically stationary. His experience of cancer of the uterus had led him to think that not more than 5 per cent. of all the cases operated upon were cured—the figures published by WINTER of the Berlin Clinic show 9.5 per cent. of cures—and he urged the extreme necessity for more careful observation of this disease and earlier recognition of it upon the part of general practitioners. The fall in the birth-rate is undoubtedly a matter of vital importance. It has fallen from 34.8 per 1000 in 1861-71 to 29 per 1000 in 1900. In suggesting a remedy for this state of things Professor BYERS thought that as medical men it was our duty to redouble our efforts to lower the present rate of infant mortality, amounting in England during the first year of life to 154 per 1000, by teaching the people to pay greater attention to rearing their children properly and by urging the public authorities to provide an adequate supply of pure milk, a matter in which America is far ahead of us. He also pointed out that we could attack this serious problem in another way by taking greater precautions when a woman is pregnant so that she may give birth to a living and healthy child; in other words, we must take care to combat all those conditions which are dangerous to the child's life before and after its birth.

#### *The Treatment of Pregnancy.*

In the *American Journal of Obstetrics* Dr. J. W. BALLANTYNE wrote a most interesting sketch of a visit to the wards of the Pre-Maternity Hospital, or a Twentieth Century Forecast, in which he painted a vivid word-picture of the hospital of the future where the practice of preventive medicine as applied to the mother and foetus in utero will be carried on—a hospital over the door of which will be inscribed the appropriate motto,

"Teach us what we shall do unto the children that shall be born." The observations which PROCHOWNICK of Hamburg has published during the past year on the influence of diet upon the nutrition of the foetus are of much importance. He claims that by placing stout women who have had difficult and instrumental deliveries upon a special diet he has been enabled to procure for them an easy confinement and an ability to nurse their children. In the case of patients with a contracted pelvis and a conjugate varying from three and a half inches to four inches he holds that he has established by his experience of 48 cases with 62 confinements that by special diet it is possible so to influence the average weight and development of the foetus as to enable it to be born at full term without difficulty in cases where on previous occasions instrumental delivery or the induction of premature labour had been necessary. These observations of PROCHOWNICK have received interesting confirmation from the experiments of Dr. D. NOEL PATON who has found that in a well-fed guinea-pig each gramme of body weight of the mother produces 0.35 gramme of young, while in a medium-fed animal the amount is 0.33 gramme of weight of young, and in an under-fed animal only 0.22 gramme of weight of young.

#### *Carcinoma of the Uterus.*

The operative treatment of carcinoma of the uterus is still claiming a great deal of attention and was discussed both at the German Surgical Congress at Heidelberg and at the Gynaecological Congress at Giessen. The great majority of the speakers were in favour of vaginal hysterectomy rather than of abdominal hysterectomy. WINTER pointed out that 134 radical abdominal operations had been performed with a mortality of 24.6 per cent., 18 of the deaths occurring from infection and 12 from collapse. At the Berlin Clinic before 1892 28.7 per cent. of all the cases were operated upon and 33 per cent. cured, or 9.5 per cent. of the whole number; at the present time as many as 48 per cent. of all the cases underwent operation, and if the relative proportion of cases cured was maintained it would amount to 16 per cent. of the whole number. At the present time the bulk of German opinion appears to favour the view largely held here in England—that very good ultimate results can be obtained by vaginal hysterectomy and that it is so far doubtful whether they are likely to be improved upon by the adoption of the radical abdominal operation with its immediate high mortality.

#### *A New Form of Uterine Atresia.*

One of the most important of all the papers published during the year is one by LANDAU upon a form of uterine atresia hitherto undescribed. The patient was a woman, 40 years of age, who had never menstruated and whose symptoms were those of uterine atresia with hæmatometra and hæmatosalpinx. By abdominal section the correctness of the diagnosis was established and the cause of the atresia was found to be a mesonephric adenomyoma occupying the position of the cervix and the vaginal fornices and completely occluding the uterine cavity. LANDAU ascribes the tumour to the inclusion in the substance of the Müllerian duct of some of the transverse canaliculi of the Wolffian body at the place where the latter is crossed by the duct. An interesting anatomical feature of the case is the fact that the cervix was the only remaining place in which mesonephric adenomyomata could occur and in which they had not yet been found, and this gap is filled by the publication of the present case.

#### *The Ingleby Lecture.*

The Ingleby Lecture was delivered by Dr. W. J. SMYLY, who selected for his address the Lower Uterine Segment and the Contraction Ring. He devoted most of his remarks to the important conditions of placenta prævia, rupture of the uterus,

and dystocia caused by the contraction ring. Amongst 76 cases of placenta prævia treated at the Rotunda Hospital, Dublin, four deaths occurred. One of the patients died from hæmorrhage after extraction of the child, two were suffering from septic infection upon their admission into the hospital, and one died from pulmonary embolism. STRASSMANN's figures from the Charité Hospital, Berlin, are quoted to show that the maternal mortality of placenta prævia treated by version by abdominal manipulation and bringing down a leg is only 1.45 per cent. Where the same method was adopted but with bipolar version the mortality was 8.6 per cent., and when version was followed by extraction the mortality was as high as 20 per cent. Cases of dystocia from the presence of the contraction ring during labour have received but scant attention from most obstetric writers, and Dr. SMYLY points out that great obstruction may be offered to delivery by this occurrence. He recommends manual dilatation where immediate treatment is imperative, but where delay is possible he agrees with VEIT's recommendation of patience and the administration of narcotics. It is important to remember that the constriction formed by the contraction ring may be present before, during, or after labour, the most familiar example of its occurrence being the so-called hour-glass contraction of the uterus producing retention of the placenta.

#### *Spinal Anæsthesia.*

The production of anæsthesia by the injection of a solution of cocaine into the spinal canal has now been carried out in a large number of very varying conditions. We gave a review of the whole subject early in the year, in which we considered its advantages and disadvantages. Nothing has been published since that time to cause us to modify our opinions as to the value of this mode of producing anæsthesia.

#### OPHTHALMOLOGY.

It is difficult in a department of medicine like ophthalmology to give any precise statement of progress. The papers that are read before societies and the articles that form the bulk of the communications to journals, contain in the majority of instances only the reports of isolated cases which, however interesting in themselves in either their pathological or therapeutic aspects, rarely lead to any material change in the views generally accepted or the measures adopted by every experienced surgeon. Protargol, for example, may be recommended by one practitioner for trachoma and cuprol by another, but the principles of treatment are not thereby altered and the real progress is small. Again, success may have attended the operation of resection of the sympathetic nerve in the neck in a few cases of chronic glaucoma, an operation that has recently been practised by Dr. GRUNERT of Tübingen, but whilst this is a fit subject for discussion in a society the results of such a proceeding in the hands of many practitioners must be tested and tabulated before the practice can become general. Such cases only form the foundation of subsequent generalisations. It is well that they should be recorded, but they are only the bricks which help to form the future edifice, and as such hardly deserve mention in this retrospect. It is only when large numbers of cases are sought out, brought together, and compared that valuable conclusions can be drawn. As an example of this the treatise on Sarcoma of the Eye by Dr. KERSCHBAUMER may be instanced, in which the author gives a short account of 67 cases of that disease and states the conclusions to which he has been led from their study as well as from the literature of the subject, the bibliography of which he gives in a catalogue of no less than 784 separate publications. The opinions of such a writer, though too long to be inserted here, naturally command attention. Another illustration of our remarks is an excellent article from the pen of Dr. W. GORDON M.

BYERS of the McGill University on Primary Intra-dural Tumours of the Optic Nerve, which appears in the first number of a new journal entitled "Studies from the Royal Victoria Hospital," Montreal. Intra-dural tumours of the optic nerve are of rare occurrence, but by diligent search Dr. BYERS has found records of 102 examples the histories of which when compared show that the characteristics of the affection are the occurrence of painless and slow exophthalmos in the forward direction, profound and early disturbance of vision with slighter ophthalmoscopic changes than might be anticipated, a palpable tumour not adherent to the walls of the orbit, relatively good movement of the globe of the eye, and a hypermetropic state of the eye from pressure. Other illustrations might be given from the excellent paper on Myopia read by Mr. PRIESTLEY SMITH before the Ophthalmological Section of the British Medical Association at the meeting at Cheltenham, which embodied the results of his numerous observations in regard to the advance of myopia of various degrees at different ages.

Before proceeding to notice the principal literary work that has been done in the past year it may be observed that the honour of knighthood has been conferred on Mr. GEORGE ANDERSON CRITCHETT, who has long been one of the most skilful, as well as one of the most successful, ophthalmic surgeons in the metropolis. Dr. DAVID LITTLE, the accomplished representative of this branch of medicine in Manchester, has been elected to the presidency of the Ophthalmological Society of the United Kingdom. The presidency of the Section of Ophthalmology at the meeting of the British Medical Association was appropriately held by Mr. WALTER H. H. JESSOP, the senior ophthalmic surgeon at St. Bartholomew's Hospital, who is a native of Cheltenham and who in his opening address discussed various points in regard to the pathology and prognosis of glioma. The chair of Ophthalmology in Paris has been resigned by Professor PANAS and Dr. DE LAPPERSONNE has been appointed in his stead.

The most remarkable work published in the course of the year is undoubtedly the "Comparative Anatomy of the Mammalian Eye," by Dr. GEORGE LINDSAY JOHNSON, which first appeared in the "Philosophical Transactions" and has since been published in a separate form. It is illustrated by drawings of the fundus of the eye in about 50 species of mammals. The aspect of the fundus in these different animals is exceedingly interesting and presents great variety. It has in each instance been beautifully depicted by Mr. ARTHUR HEAD. In some the optic disc is dark-red or almost black; in others it is white. In some the choroidal vessels are very distinctly marked; in others they are invisible. The choroidal pigment is scanty and irregularly distributed in some; in others it is disposed in plaques or spots with the greatest regularity. In some the retinal vessels are large and numerous and spring from the centre of the disc or from its margin; in others there is not a vestige of them. The appearances presented by the tapetum are instructively shown, and when it is added that the fundus of the eye is depicted in such animals as the camel, the wild boar, the seal, the hippopotamus, the elephant, the bear, the skunk, the hyena, and many others, it is obvious that time, skill, courage, and patience—and, it may be added, money—must have been expended in obtaining such excellent results. A cheap but useful Atlas of the External Diseases of the Eye, constituting one of Lehmann's "Hand Atlanten" and containing 80 illustrations by JOHANN FINK, has been brought out by Professor O. HAAB of Zürich as a companion volume to his "Ophthalmoscopie."

#### *Glaucoma.*

The value of iridectomy in glaucoma was the subject of an animated and important discussion in the Congress of the Société Française d'Ophthalmologie, in which many of

the leading ophthalmologists in Paris took part. M. L. DE WECKER, who acted as reporter, gives the history of VON GRAEFÉ's operation accompanied by iridectomy, followed by HANCOCK's division of the ciliary muscle without iridectomy, and the various modifications of sclerotomy or of iridectomy suggested by M. DE WECKER himself, Professor QUAGLINO, and others, the extra-ocular operations of stretching the external nasal nerve proposed and practised by BADAL, the resection of the superior cervical ganglion of the sympathetic practised by JONNESCO, and, finally, the employment of myotics. The value of the last named very simple means of relieving the symptoms of glaucoma is indubitable, but the consensus of opinion was that it should not be used so persistently as to cause the period during which iridectomy can be performed with advantage to be overpassed. The operation of iridectomy was held to be of little or no value in cases of chronic glaucoma without increased tension, but almost all the speakers expressed decided views in regard to the beneficial influence of iridectomy in acute and subacute cases, the effects of which were better the earlier it was resorted to. M. DARIER observed that where for any grave reason iridectomy could not be practised other means were at the disposal of the surgeon—such as the use of dionine, which alleviates pain and promotes the circulation of lymph; of surrenaline, or extract of the supra-renal bodies, which diminishes intra-ocular pressure and the secretion of aqueous humour; of myotics, which diminish the tension of the globe, contract the pupil, and thus enlarge the absorbing surface of the iris; or of massage-pressure, which when well executed is capable of reducing the tension of the eye in a few minutes from T + 2 to normal tension. Glaucoma, as it occurs in the East, in Turkey and in Egypt, has been specially described by Dr. G. BITZOS of Constantinople. It presents in Turkey only glaucomatous papillitis, glaucomatous pitting of the disc, and the local troubles consequent on these. There is no pain, there are no haloes, and there is but little increase in tension. Primary glaucoma is twice as frequent in Constantinople as compared with Paris and secondary glaucoma is four times as frequent.

#### *New Remedies.*

The new, or comparatively new, remedies that have been found useful in diseases of the eye are acoine, which acts as a powerful anæsthetic when subconjunctivally injected, though useless when its solution is merely instilled into the conjunctival sac; dionine, which is said to aid atropin in dilating the pupil and to act as an antiseptic and an analgesic; cuprol, which is a nucleinate of copper and is strongly recommended by Mr. SIMÉON SNELL as less irritating than the pure sulphate; actol, which is lactate of silver; itrol, or citrate of silver; argen-tamine; argonine or argentum casein; nargol, or nucleate of silver; largin; and especially protargol, which is a compound of silver with vegetable albumin; most of these are substances to which Mr. HARTRIDGE called attention at the Cheltenham meeting of the British Medical Association as new and serviceable remedies for the superficial affections of the eye.

The presence of a specific form of bacillus in that species of conjunctivitis in which the secretion contains fibrinous flocculi was pointed out by Dr. V. MORAX in 1896. His statements were, however, at first received with some incredulity by ophthalmologists. Quite recently, however, several observers have substantiated Dr. V. MORAX's discovery and have been successful in effecting pure cultures of the bacillus which he described as resembling Friedländer's pneumo-bacillus, from which, however, it differs in being longer and destitute of a capsule. As has been recently stated in our columns, the bacillus will live for some days in an aseptic tube and though exposed to light preserves its virulence. When

placed in the conjunctival sac it sets up conjunctivitis with fibrinous flocculi in the secretion in the course of five days. It does not appear to affect animals and it is killed in a quarter of an hour by exposure to a temperature of 58° C.

The pathogeny of exophthalmic goitre was the subject of two papers read at the meeting of the British Medical Association. In one of these Dr. E. GLEY of Paris, after reviewing the various theories that have been advanced, expressed his opinion that this disease is due to an alteration in the thyroid apparatus primarily involving the parathyroid, the normal function of which is abolished. In the second paper Mr. WALTER EDMUNDS detailed the changes which he had observed in the nervous system as the result of the removal of the thyroid and parathyroids. The "Nissl bodies" in the nerve cells were no longer defined and the chromophilous substance was either absent or much reduced in quantity, whilst the nucleus was swollen. The consequences of the operation render it probable that the absence of the parathyroid secretion is in some way the cause of the acute symptoms, its presence being probably necessary for the formation of the Nissl bodies which are supposed to be the food of the cells. The sequelæ of gonorrhœa, apart from purulent ophthalmia, have been embodied in a good paper by Mr. J. B. LAWTON, who finds that the most common secondary affections are arteritis, conjunctivitis, iritis, and irido-cyclitis, then scleritis and episcleritis, and, finally, retinitis and neuro-retinitis.

#### *Cataract.*

Many communications from surgeons practising in India were published in a special number of the *Indian Medical Gazette* showing that in that country the results of cataract operations are far more successful than in the European hospitals. It may be regarded as doubtful whether any English or continental surgeon has had, taking the good cases with the bad, 100 successful operations without a failure, yet in this remarkable collection the operators speak of 200 and even 300 consecutive successes. Lieutenant-Colonel T. H. POPE, I.M.S., in particular is able to point to an experience embracing 4000 cases and he has given an excellent account of the precautions to be adopted as well as of the mode of operating most likely to conduce to a successful result in cataract operations. Major H. HERBERT, I.M.S., records a series of 497 operations in which a solution of one part of corrosive sublimate in 3000 parts of water being freely applied complete exemption took place from grave infection. The results of other operators recorded in the same journal are scarcely inferior and fully justify the dictum of Professor FUCHS that the greater the operator's skill grows with practice the less frequently do unlucky accidents happen to him. The etiology of lamellar cataract as elucidated by a consideration of the dental lesions that are frequently associated with it has been discussed by Mr. NORMAN G. BENNETT, who shows that in many instances lamellar cataract is associated with a hypoplastic condition of imperfect development of the teeth and that both the dental and the ocular lesions are the results of the same general conditions—as, for example, of rickets, of convulsions in infancy, of exanthematous diseases, or of imperfect nutrition from insufficient or inappropriate feeding.

#### *Retina.*

Although it is well known that dilatation of the pupil can be excited by psychical stimuli as well as by strong electric stimulation applied to any part of the central cortex the observations and experiments of Dr. J. H. PARSONS seem to prove that in the absence of the usual dilator tracts through the sympathetic nerves dilatation of the pupil is due to inhibition of the tonic influence of the third pair of cerebral nerves.

The differences between the rods and cones of the retina are so marked that it is reasonable to believe that they

fulfil different purposes, and Mr. F. W. EDWARDS-GREEN has adduced various reasons for holding that whilst the rods liberate visual purple, the cones with the optic nerves receive and convey to the visual centre of the brain the impress of the chemical changes taking place in the retina. Dr. G. MARENGHI has observed that intracranial section of the optic nerve does not abolish the reflex action of the pupil to light probably owing to the existence of a peripheral reflex centre.

The injurious effects of tobacco and alcohol upon the eyes are well illustrated in a paper by Dr. C. E. FINLAY, who gives the results of his experience in the island of Cuba, where in the course of eight years' practice, during which he has had 4300 cases, he has treated 92 patients for trouble arising from these causes. The white race suffered more than the dark, and the failure of vision usually occurred between the ages of 30 and 50 years. The symptoms were pallor or atrophy of the temporal segment of the optic discs, diminution of visual acuity, and central scotoma at first for red and green and then absolute. Of the 92 cases 23 were acute, 48 were chronic, and there were 17 cases of partial and four of total atrophy.

Various cases of gunshot wounds of the head have been published by Mr. E. TREACHER COLLINS, Dr. J. S. HINNELL, Mr. E. NETTLESHIP, and others, the most important corollary from which is that where minus tension exists after a violent indirect injury of the eye, it is not necessary to assume that the lowered tension necessarily means wound or rupture of the globe.

#### *Bibliography.*

Amongst the more important works, besides those already mentioned, which have been published during the year are the following: "Essentials of Refraction," by E. JACKSON; "The Relations of General to Ophthalmic Disease," by GRUNOW and UHTHOFF; the second part of HIRSCHBERG'S "Introduction to Ophthalmology"; Dr. PERCIVAL'S "Periscopic Lenses"; "The Microscopic Examination of the Eye," by R. GREEFF; and the twenty-first volume of the Transactions of the Ophthalmological Society of the United Kingdom. To these need hardly be added the *Ophthalmic Review*, Dr. KNAPP'S *Archives of Ophthalmology and Otolaryngology*, and the numerous French and German periodicals which are store-houses of ophthalmological work and are sufficiently familiar to the diligent observer.

#### FORENSIC MEDICINE.

Of criminal trials during 1901 that of CZOLGOSZ for the murder of President MCKINLEY stands in bold relief. The murderer, an anarchist, mortally wounded his victim with a revolver shot. As we remarked in a previous number, Mr. MCKINLEY was singled out for vengeance "simply and solely because he represented government." The prisoner was convicted of the capital offence in the first degree, condemned, and electrocuted.

Of trials for murder in this country the most notable was that of HERBERT JOHN BENNETT which took place at the Central Criminal Court before the Lord Chief Justice. The prisoner, who was accused of feloniously slaying his wife at Yarmouth by strangling her with a boot-lace, had treated her with persistent neglect and cruelty. Beyond the long-evinced desire to be rid of what he looked upon as an incumbrance he had become engaged to a young woman and had arranged to marry her. This, it seems, was the immediate motive for the crime. A more deeply planned scheme for the execution of the fell design and for hiding the evidence of guilt has been rarely equalled. The prisoner expiated his offence by undergoing the extreme penalty of the law. It will be remembered that by writ of certiorari the venue of the trial was removed from the Norwich Assize Court to the Old Bailey in consequence of the representation that a fair

hearing might not be obtained at the former court on account of the strong local feeling against the prisoner.

At the same sessions, before Mr. Justice PHILLIMORE, GEORGE HENRY PARKER was convicted and sentenced to death for the murder of Mr. W. PEARSON on the South-Western Railway. The murderer and victim were unknown to one another. They chanced to travel in the same train. Whilst Mr. PEARSON was asleep PARKER shot him with a revolver and robbed him of his money. Premeditation undoubtedly there was, but not of the nature commonly presented in cases of wilful murder.

Mr. Justice PHILLIMORE also tried the case of MAUD EDDINGTON who was indicted for the alleged murder of her sweetheart, JOHN BELLIS, by shooting him with a revolver. The jury adopted the view put forward by her counsel, Lord COLERIDGE—viz., that BELLIS was shot accidentally whilst attempting to prevent EDDINGTON from taking her own life. For the latter offence she was sentenced to a term of imprisonment.

CHARLES WILLIAM BROWNING was convicted of having made a false representation of his death with intent to having the same registered contrary to the Act. The prisoner had been a medical student and thus had acquired the knowledge to simulate a case of acute Bright's disease, and successfully to impose upon a medical man, Mr. G. W. B. MARSH, who issued a certificate of "death from uræmia consequent on acute nephritis." We subscribed to the proposition that it should be mandatory on medical men not only to "certify the cause of death, but also to verify the fact of death."

At the Old Bailey a medical man was indicted for the murder of a married woman living apart from her husband by illegally procuring abortion upon her. The only direct evidence was furnished by the deceased in a dying declaration taken before a Justice of the Peace. At the trial Mr. Justice BRUCE ruled that the declaration was inadmissible, inasmuch as "it was not made in the settled hopeless expectation of immediate or almost immediate death." Upon this decision the prosecution was abandoned. Without strong corroborative evidence the testimony of the woman, an accomplice, would have been held no doubt by the jury as unconvincing.

At the Bristol Assizes a man and woman were convicted of having attempted to murder by illusage and starvation the son of the male prisoner, aged 11 years. The man was sentenced to 15 years' and the woman to five years' penal servitude. Arising out of the case the publisher of a weekly paper and a reporter, designated a "crime investigator," were sentenced to imprisonment in the second division for having interfered with the course of justice by publishing facts relating to the crime before the trial of the accused and thereby unfairly prejudicing their interests. The conviction was sustained on appeal to the King's Bench.

T. R. ALLINSON, ex-L.R.C.P., was summoned before Mr. CURTIS BENNETT for issuing obscene literature in the guise of "medical advice." He was bound over in the sum of £250 to come up for judgment if called upon and the "literature" was ordered to be destroyed.

The Sheffield Recorder heard a charge against two medical men—the one as principal and the other as abettor—for having certified that a child was stillborn, whereas it lived for 12 hours. The abettor was acquitted by the direction of the Recorder and the jury acquitted the principal of illegal purpose but found that he had been guilty of gross negligence.

A man named HENRY DAVIS was fined £20 and costs by Mr. CURTIS BENNETT for unlawfully assuming the title of "Dr."

Several civil actions of interest to the medical profession have been determined. In the case of CUNNINGHAM v. *The Daily Express* an action for libel was brought by the plaintiff

against the defendant for having published the statements that he advertised "a sham and pretended cure for consumption," and that he was a quack and charlatan. The jury marked their sense of justice by stopping the case whilst the defendant was giving his evidence.

A Mr. ROBERTSON sued a firm of druggists at Glasgow for damages, and the jury awarded him £700. Mr. ROBERTSON left some prescriptions with the defendants to be dispensed. Instead of a mixture an assistant sent a bottle of liniment containing chloroform, belladonna, and aconite. The plaintiff inadvertently drank some of the liniment to the serious detriment of his health. On the contention that the damages were excessive the court remarked that the defendants had two chances of correcting their mistake, of neither of which they availed themselves.

GWYNNE v. GREVILLE was an action for damages against the Medical Electro-Thermic Generating Company, Limited. The defendant, as manager of the company, had supplied to the plaintiff apparatus for the application of dry heat. It was contended on behalf of the plaintiff that she had suffered from burns owing to insufficient packing. The jury awarded a farthing damages. We took occasion to remark that a medical man should always personally supervise the application of powerful agents.

In the case of STOCKS v. CROSSMAN and WATSON the plaintiffs, medical practitioners, sued for payment of fees, whereas the defendant made a counterclaim for £250 for damages on account of disablement owing to the alleged carelessness and unskilful treatment of one of the defendants. As the amount of the counter-claim was over £50 the cause was removed from the County Court to the High Court. It was contended that one of the medical men had failed to diagnose a dislocation of the shoulder. To this he made answer that the luxation occurred at a time subsequent to the date of the alleged malpraxis. After a careful and lucid direction by Mr. Justice BRUCE the jury returned a verdict for the defendants. Costs were awarded on the High Court scale both on the claim and counter-claim.

On the subject of poisons we drew attention to an interesting case of poisoning by creasote recorded by Mr. H. M. HEWLETT in the *Intercolonial Journal of Medicine of Australia* on Oct. 20th, 1900. A girl, aged three and a half years, swallowed two drachms of the drug. The symptoms were abdominal pain, rapidly ensuing unconsciousness, pallor of the face, cyanosis of the lips, shallow respiration, imperceptible pulse, fixation of the eyes, contraction and immobility of the pupils, and flaccidity of the muscles. The stomach was washed out with warm water and with a strong solution of magnesium sulphate and one-twenty-fifth of a grain of strychnine was injected hypodermically. The urine was of a dark-brownish colour for several hours and then of a watery green. We directed attention to the fact that creasote was less caustic than, and did not cause convulsions like, carbolic acid.

In the Journal of the American Medical Association Dr. H. MOULTON related a case of poisoning by bay rum. The most important symptom was temporary blindness. This has been noticed in other cases where liquids containing large quantities of methyl alcohol have been swallowed—e.g., "Jamaica ginger."

A singular case of belladonna poisoning was related in our columns. A lady applied a belladonna plaster for muscular pains the result of excessive exercise and a chill. The symptoms were characteristic—dryness of the throat and mouth, dilatation of the pupils, and loss of power of controlling movements. Recovery was rapid and complete.

Fungus poisoning accounted for serious symptoms in three children who had eaten a fungus—probably agaricus—in mistake for mushrooms. In one of the patients there were twitching and grinning of the face and inability to speak. The nervous symptoms seemed to have occurred before, and

were in excess of, the alimentary disturbance. Recovery took place after vomiting had been induced by hypodermic injection of apomorphine.

Several cases of fatal poisoning by cocaine have occurred. In some the agent was taken in excess by misadventure, whilst in others there was obviously suicidal intent. The most painful instance of the latter was that in which two young ladies—actresses—resolved to die together in consequence of ill-health and the mental strain incidental to varying fortune in their exacting profession. It seems high time that the ease with which large quantities of cocaine can be obtained by the laity should be prevented.

Boric acid has had more than its due share of legal investigation. Convictions have been obtained for using the drug as a food preservative. At Morecambe a dealer was fined £20 and costs for selling three pints of shrimps which were mixed with boric acid in the proportion of 95 grains to the pound. As bearing on the commercial use of boric acid as a preservative of foods we have drawn attention to two cases of poisoning recorded by Dr. J. F. RINEHART in the *Therapeutic Gazette* for October. In the first case a man, aged 39 years, suffering from posterior urethritis, was given five grains of boric acid every four hours by the mouth. In two or three days he became very weak and vesicles formed on the back of the hands and between the fingers. The pulse was weak but not accelerated. The symptoms disappeared on discontinuance of the boric acid and reappeared when its use was resumed. In the second case a male, aged 50 years, upon whom suprapubic lithotomy had been performed, was given five grains of boric acid every four hours by the mouth, and a saturated solution was used to wash out the bladder. Cardiac depression followed and there was an erythematous rash about the wound and the lower part of the abdomen. In this case also the results disappeared when the employment of the acid was abandoned and reappeared on its resumption.

Again, unfortunately, we have had to chronicle numerous cases of chloroform toxæmia. A drastic procedure, but one which we felt justified in approving, has been introduced to avert disaster in cases in which the usual methods of restoration have failed. We refer to cardiac massage.

Dr. FREYBERGER, in *Treatment*, January, 1901, records a case in which the heart was exposed by dissection and compression applied to its walls. Although death ensued the heart continued to beat for nearly eight hours, but no natural respiratory movements occurred. Perflation of the lungs was in the meantime kept up.

At the Seamen's Hospital, Royal Albert Docks, a man, aged 42 years, succumbed to chloroform poisoning. Mr. J. CANTLIE cut down on the heart, opened the pericardium, and compressed the ventricles. The pole of a battery was applied to the heart. The treatment in this case seems to have met with little response. At the necropsy the heart and other viscera were found to be healthy.

#### DENTAL SURGERY.

One of the features of the past year has been the recognition by the War Office authorities of the value of dental services to the army. Four dental surgeons have already been sent to South Africa, and more appointments are shortly to be made, while at home a dental surgeon has been appointed to the forces stationed at Aldershot. It is most important that those appointed to these posts should be men qualified after curriculum and if possible also holders of a medical qualification. If the best men are to be obtained the appointments must be thrown open to competition and the merits of the various candidates decided by the authorities at the War Office with the aid of a dental practitioner.

The opening of the new buildings for the Royal Dental Hospital of London must be regarded as another feature of the past year. The building is all that can be desired

and the laboratories for teaching are replete with every modern appliance. Nothing, perhaps, brings home more vividly the great strides made in dental surgery during the last 30 years than a comparison between the buildings of the hospital in Soho-square in the early "seventies" and the present structure in Leicester-square.

#### Education.

Educational matters have received their quota of attention and one or two changes have been made in the English curriculum. Courses of instruction in dental bacteriology and materia medica have been added to the curriculum, while the final examination has been divided into two parts: (1) the general portion; and (2) the purely dental portion. The two parts can be taken together or separately. An association known as the International Dental Federation held its first meeting in Cambridge during August. The subject under discussion was the teaching of the dental student. For some reason those most interested and best qualified to speak on dental education in this country held aloof from the meeting. This is to be regretted because the views expressed by some of the English members were quite at variance with those held by the majority of regular teachers. It is very difficult for those unacquainted with the teaching of dental students to be able to formulate views of any value in dental education.

#### Papers.

Several interesting and suggestive papers have been contributed to the journals during the past year. The subject of the movements of the mandible has formed the theme of an interesting discussion and the papers contributed by Mr. C. S. TOMES, Mr. W. H. DOLAMORE, and Mr. T. CONSTANT have shown that it is by no means an easy task to demonstrate the exact movements which take place in opening and closing the mouth. Mr. KENNETH W. GOADBY has again added to our knowledge of the micro-organisms of the mouth; and his paper, published in the October issue of the *Journal of the British Dental Association*, shows that distinct advance is being made in the elucidation of the etiology of dental caries. Mr. T. G. READ's paper on the Chemical Changes Occurring in the Mouth during the Mastication of Bread composed of Roller-milled Flour opens up an important field for observation. His contention that roller-milled flour produces acid in the mouth much more quickly than does stone-milled flour is worthy of careful consideration and investigation. A suggestive paper on a case of Burrowing Epithelioma of the Alveolar Process was read before the Odontological Society by Mr. STANLEY W. R. COLYER. Mr. J. G. TURNER also brought before the same society the subject of the Relation of Simple Pedunculated Fibrous Epulis to Supernumerary Teeth. A valuable paper by Dr. C. LEE on Ulcero-membranous Gingivo-stomatitis appeared in *Dental Cosmos* of February. This paper is well worthy of careful perusal.

#### Operative Dentistry.

In operative dentistry a welcome advance has been made in the preparation of amalgam fillings. Porcelain inlays have attracted a considerable amount of attention and the method of preparing inlays has been improved. In the diagnosis of irregularities in position of the teeth the x rays have been more generally employed, but there is still room for improvement.

#### New Books.

Amongst the new publications of the year are to be noted: "Oral Sepsis as a Factor in Disease," by Dr. W. HUNTER; the second edition of "Diseases and Injuries of the Teeth," by Mr. MORTON SMALE and Mr. J. F. COLYER; the fourth edition of Mr. HENRY SEWILL'S "Dental Surgery"; "The Treatment of Mal-occlusion of the Teeth and Fractures of the Maxillæ,"

by Dr. ANGLE; the fourth edition of Dr. TALBOT'S "Irregularities of the Teeth"; the "Principles and Practice of Operative Dentistry," by Dr. J. S. MARSHALL; and the second editions of the American Text-books of Operative and Prosthetic Dentistry.

#### Obituary.

The death-roll for the year includes the name of Sir EDWIN SAUNDERS, who was for many years dental surgeon to Her late Majesty Queen VICTORIA. He took a great interest in the Dental Hospital of London and he will always be remembered by the scholarship which bears his name.—Mr. ROBERT HEPBURN passed away at the ripe age of 91 years. He was one of those who took part in the early struggles to obtain for dentistry a legally qualified position. He was one of the original surgeons to the Royal Dental Hospital of London and was the first lecturer on mechanical dentistry in the medical school.—The death of Mr. HENRY BARRETT has also removed another of the early pioneers of dental reform.—The dental profession in Canada, by the death of Dr. W. G. BEERS, has been robbed of one of its most able and enthusiastic workers. Dr. BEERS will be remembered in the field of sport as the father of lacrosse.

#### ANATOMY AND PHYSIOLOGY.

In the wide domain of biology innumerable naturalists and keen observers have each added their mites to the sum of human knowledge and it needs but to open the books which are issued by the many societies that have sprung up of late years to see how vast is the accumulation of facts that have been placed on record even in the short space of 12 months. The Ray Society, for example, has published a valuable monograph by Mr. ROBERT NEWSTEAD on the Coccidæ of the British Isles, known to gardeners under the common name of mealy-bugs and scale-insects, which are not the least injurious amongst the many foes of plants. The journals of the Linnæan Society again gives long descriptions of new species of many genera of animals and plants either collected in England or brought home from such remote regions as Funafuti, and the Tonga Isles, from the Andes, and from Japan. The Zoological Society's "Record of Progress" shows how much has been done to familiarise the inhabitants of these islands with strange and foreign animals previously known only by the statements of travellers. Amongst the most remarkable of these, though not as yet obtained in the living state because probably representing one of the last of the undescribed larger mammals on the earth, is the *Okopia Johnstonii* from the forests bordering the Congo.

The Hunterian Oration was delivered at the Royal College of Surgeons of England by Mr. N. C. MACNAMARA who took for his subject the advances that have been made of late years in our knowledge of prehistoric man, illustrating his discourse by the splendid collection of crania, commenced by JOHN HUNTER and continued by the successive curators of the museum, now in the possession of the College. Another important lecture—the Croonian—was delivered before the Royal Society by Principal LLOYD MORGAN, who selected for his subject visual sensation and described an attempt which he had made to frame a scale of visual sensation analogous to, and in correlation with, a scale of physical luminosity by means of rotating discs. The section of Anatomy and Physiology in the meeting of the British Medical Association at Cheltenham had the advantage of the presidential address being in the hands of Professor A. MACALISTER.

In September Lord LISTER opened a new and well-appointed anatomical department in the University of Glasgow, the erection of which is due to the liberality of the trustees of the late Mr. J. B. THOMSON, a well-known and wealthy ship-builder of that city. The University of Edinburgh has been equally fortunate since, in July, the

Hughes Bennett Laboratory of Experimental Physiology, founded by Mrs. COX as a memorial of the work of her father, Professor J. HUGHES BENNETT, was formally presented to the University. Mention must also be made of the munificent donation of £2,000,000 for the promotion of education in Scotland by Mr. ANDREW CARNEGIE. It may be noted in passing that the eightieth anniversary of the birthday of Professor VIRCHOW was the occasion of a large gathering of men representing many branches of science to do honour to the physiologist who first enunciated the important dictum of "*omnis cellula e cellula*."

The action of light on plants and animals has been investigated by M. C. FLAMMARION who has thus instituted a new department of science which he terms "radio-culture." His experiments show that in the case of the eggs of silkworms darkness is unfavourable and orange and red rays are favourable to development. Moreover, exposure to rays of light of different colours seems to exert a powerful influence on the production of the two sexes, for whilst in ordinary solar light the males and females issuing from a large number of eggs are about equal in number, or 50 per cent. of each, when exposed to clear or sky blue the proportion is 57 per cent. of males and 43 of females, deep violet gave 62 males to 38 females, orange 64 males to 36 females, and deep red 68 males to 32 females. The singular predilection of the *Anopheles* mosquito for dark colours has been noted by Dr. NUTTALL and for sounds by Mr. BRENNAN.

Dr. A. D. WALLER has made a series of interesting experiments on vegetable electricity, which show that even slight mechanical excitation of growing and tender plants as, for example, a vine shoot, is capable of rendering the excited spot electro-positive to unexcited parts, the electro-motive force amounting in some instances to as much as 0.02 volt. This current is abolished at high and low temperatures. Dr. WALLER also finds that the leaves of various plants, such as those of tobacco, begonia, and iris, are rendered electro-positive in that part on which light falls, as compared with unilluminated parts. Other papers and articles dealing with the relations of electricity with the living organism have been written by Dr. MAX OKER-BLOM, who in an elaborate article contained in PFLÜGER'S *Archiv für Physiologie* attempts to explain the phenomena of living beings as essentially the result of physical and chemical processes; by Professor H. BORUTTAU, who has studied action currents and the theory of nerve conduction; and by Professor BR. WERIGO, who also endeavours to explain the depressing action of the cathode on nerve conduction.

#### Nervous System.

At the Fifth International Congress of Physiologists, held in the summer at Turin, high honours were conferred upon Sir MICHAEL FOSTER in recognition of his work in founding the School of Physiology at Cambridge which now ranks amongst the foremost in the world for equipment, position, research, and work done. He was made perpetual president of the society and was presented with a complimentary address and medal. At this Congress an important paper was read by Professor C. S. SHERRINGTON, who with Dr. A. S. F. GRÜNBAUM has investigated the motor representation in the cortex of the brain in the anthropoid apes. Electric stimulation was applied in some cases and the removal of parts was practised in others, with the subsequent examination of degenerated tracts. The results obtained were that in these animals some modifications of the generally accepted disposition of the motor areas are required. The positions of these areas, for example, were shown to be all situated in front of the fissure of Rolando. The problem of mapping out the motor areas in the brain was attacked in a different way by Professor FLECHSIG, who gave his conclusions to the same meeting in another paper. The plan adopted by him, which has been followed out with

much success, was to investigate the order in which development as exhibited in the successive myelinisation of groups of nerve-fibres takes place. Another line of research which may lead to important results has been opened up by Professor J. N. LANGLEY, who has observed that nicotine and several other alkaloids stimulate certain parts of the nervous system whilst they are without action on others. Thus, whilst they stimulate the nerve-cells of the sympathetic ganglia they have no influence on the cells of the spinal ganglia, nor on spinal nerve-fibres, nor their endings. At the suggestion of Professor A. VAN GEHUCHTEN, one of his pupils, A. LUBOUSHINE, has followed out degenerative changes occurring after lesions of the spinal cord. Amongst other results he finds that the fasciculus of Gowers is composed of two sets of fibres, one originating in the cells of the grey substance of the posterior cornu of the same side, and the other in the corresponding cells of the opposite side. Professor VAN GEHUCHTEN has himself carefully examined the ascending lateral columns, whilst FRITZ DE BEULE describes the degenerative processes in the cells of the hypoglossal nucleus after tearing away the hypoglossal nerve. In a paper read before the Parisian Academy of Sciences M. LAPIQUE gave the results of numerous experiments which he had made on different races in the course of a voyage round the world to determine the reaction time of the nervous centres to stimuli, which he found to be in the following order: Europeans, 0.15 second; Andaman Islanders, 0.19 second; Hindoos, 0.22 second; poor of Paris, 0.18 second; students, 0.15 second; and three Paris workmen, 0.17 second. N. MISLAWSKY of Kasan has shown that stimulation of the centrum tendineum of the diaphragm or of the peripheric extremity of the cut phrenic nerve is followed by arrest of the respiration in the expiratory phase, providing the vagi are intact. Much information in regard to the innervation of the skin in man will be found in an article by Dr. A. LEONTOWITSCH in the *Internationale Monatsschrift für Anatomie und Physiologie*.

In most of the text-books in which the subject is mentioned at all the inexcitability of the grey matter of the spinal cord is accepted on the authority of SCHIFF and BROWN-SÉQUARD, but M. VITZOU, in a paper read before the Paris Académie des Sciences, stated that in the horse he had satisfied himself that the grey matter exposed on the floor of the fourth ventricle responded to electrical stimulation. With the able coöperation of Dr. F. W. MOTT, researches into the effects of Wallerian degeneration upon the chemical composition of nerves have been carried out by Dr. W. D. HALLIBURTON, who has found that choline, a toxic substance, and phosphoric acid were prominent and early-appearing products. The question of the presence or absence of vaso-motor nerves distributed to the cerebral vessels has generally been answered in the negative, and the numerous experiments of Mr. LEONARD E. HILL and of Dr. J. J. R. MACLEOD support this view, for they have found that the circulation in the brain passively follows every change, however slight, either in arterial or venous pressure. At the same time they think that it would be rash to deny altogether the existence of such nerves, notwithstanding that the vessels of the brain behave, both in regard to the influence of asphyxia and to the intravenous injection of suprarenal extract, in a very different manner from those of the fore-limb. On the authority of Dr. JOHN REID it has been very generally maintained that section of one vagus was dangerous to life, but that section of both these nerves was invariably fatal owing to loss of sensibility of the glottis and to the occurrence of pneumonia as a result of the entry of foreign bodies into the lungs. Two Russian physiologists, however, P. KATSCHKOWSKY and Professor J. P. PAWLOW, have kept dogs alive for many months after section of both nerves by taking the precaution to make a gastric or an œsophageal fistula through which the animal was

fed on appropriate and carefully selected diet, whilst putrefactive processes were at the same time prevented by washing out the contents of the stomach soon after digestion was completed. NICOLAIDES of Athens found also that dogs survived double division of the vagus, provided some days were allowed to elapse between the division of the two nerves. The intestine was noticed to be the vulnerable part in these animals, the smallest injury in this region leading to death.

#### *Organs of Digestion.*

The topography of the thoracic and abdominal viscera was the subject of a discussion at the meeting of the British Medical Association at Cheltenham, following the reading of a paper of great value by Professor CHRISTOPHER ADDISON on that subject.

Whilst many analyses have been made to determine the amount of nitrogen and of fat contained in the feces few have been directed to determine the presence and quantity of starch. Dr. J. STRASSBURGER has attempted to supply this hiatus by estimating the quantity of sugar that can be formed from the feces, but upon a mixed diet he finds that only a small quantity of sugar can be obtained, showing that in man starch undergoes nearly complete digestion and absorption in its passage through the alimentary canal. The researches of Professor A. HERZEN on digestion show first that dextrin is a powerful pepsin-forming substance, whilst extract of meat is chiefly though not exclusively useful in producing an abundant secretion of gastric juice and thus promoting digestion of other substances. He also finds that the spleen generates as an internal secretion a material not yet isolated which has the property of converting protrypsin into trypsin. The effects of extract of pancreas in converting casein into metacasein, which is recognised by its coagulability on boiling, is due, according to Dr. H. M. VERNON, not, as Sir WILLIAM ROBERTS thought, to trypsin, but to rennin. The gaseous metabolism of the submaxillary gland, which has only once before been investigated—namely, by CHAUVÉAU and KAUFMANN in the horse—has been the subject of careful examination by Mr. JOSEPH BARCROFT. The results show that during the secretion of saliva induced by stimulation of the chorda tympani both the oxygen taken from the blood and the carbonic acid given off are three or four times greater than in the resting gland, and they show in addition that on paralysing the secretory activity of the gland with atropin the intake of oxygen is not increased on stimulation of the chorda tympani, whilst, for a time at least, the output of carbonic acid is greatly increased. Measurements have been made by Dr. A. L. GILLESPIE which serve in some measure to account for the astonishing differences in the quantity of food consumed by different persons, his examinations of the capacity of the stomach showing extremes of two ounces and 160 ounces.

Any contribution to our knowledge of the process and activity of absorption by the intestine is to be welcomed on account of the frequency with which life has to be maintained by means of nutritious enemata. Dr. FELIX REACH, employing solutions of albumose and of gelatin with and without the addition of common salt, has shown that the absorption of these substances takes places with much greater rapidity in the small than in the large intestine. Gelatin solution is absorbed in the large intestine with greater difficulty than a solution of albumose, but the addition of (0.7 per cent.) solution of common salt to the gelatin solution equalises them, but if salt be added to the solution of albumose in excess it interferes with absorption and by irritating the mucous membrane may altogether prevent absorption. When gelatin solution is used as an enema common salt solution of the above strength may with advantage be added to it. In the small intestine albumose-solution

is absorbed more rapidly than gelatin-solution, the addition of common salt proves of no service in case of the gelatin, whilst if mingled with the albumose it sets up irritation. Various experimenters have shown that fat is absorbed with great difficulty in the large intestine unless in a state of fine division which suggests that the condition of emulsions when employed as nutritive enemata should receive particular attention.

The experiments that have been made on alcohol will be a source of satisfaction to abstainers, though they will probably have little influence in diminishing its consumption. The value of alcohol as a food in the case of a dog of moderate size was the subject of experiment lasting for a whole year by M. A. CHAUVÉAU, who finds that whilst alcohol rapidly enters the circulation it participates in a very slight degree only in the combustions from which the muscular system draws the energy requisite for its work. It is not an aliment in any sense of the word, and even when the economy is quite saturated with it it is unable to be utilised, either by the tissues in repose or by the muscles in action. Experimenting with guinea-pigs M. L. ROOS is only able to say that the administration of a certain quantity of wine equal to what would be two litres for a man per diem did neither good nor harm; whilst Herr C. RADZIEKOWSKI finds that alcohol is not a pepsin-former, but that it promotes the secretion of gastric juice if introduced into the stomach and to a small extent, but still perceptibly, if injected into the rectum. In the frog Professor LEE and Dr. W. SALANT of New York found that minimum doses of alcohol had no effect; moderate doses, from one to four minims of a 10 per cent. solution of alcohol in water per gramme of body-weight, greatly augmented the amount of work done, whilst large doses reduced it. The gastric ferments have been investigated by Dr. ALEXANDER WINOGRADOW, who regards the lab-ferment or chymosin to be the main agent in the reconversion of the soluble and easily osmosable peptones into the albumins found in the blood. Trainers will read with interest an article in PFLÜGER'S *Archiv für Physiologie* upon Diet in Training by Dr. H. LICHTENFELT, in which he shows how surprising is the amount of food required or, at least, taken by men in training, for whilst the average man doing a fair day's work requires 140 grammes of proteids, 100 grammes of fat, 350 grammes of carbohydrates, and in addition salt and water, the football team of California University consume daily 270 grammes of albumin, 416 grammes of fat, and 710 grammes of carbohydrates—a truly colossal amount.

#### *Blood Organs of Circulation.*

The number of blood platelets in a cubic millimetre of human blood has been counted by Mr. G. KEMP and Miss H. CALHOUN, who find that it varies from 730,000 to 961,500. They were unable to satisfy themselves that the platelets contain hæmoglobin or that they develop into blood corpuscles. The seasonal and periodic changes in the proportion of corpuscles in the blood of the frog have been studied by GAULE with the astonishing result that the male of the ordinary frog (*Rana temporaria*) may have at one time 1,200,000 blood corpuscles per gramme of body-weight and at another 24,000,000 or even 35,000,000. Do variations of a similar kind occur in the higher animals? The subject seems to be one that is worth pursuing. Professor WERIGO and one of his pupils, L. JEGUNOW, have made some curious observations on the effects of injecting into the blood fluids containing various kinds of bacteria. A few minutes after the injection a very great diminution in the number of the leucocytes occurs and especially of the polymorpho-nucleated leucocytes which retreat into the lungs, liver, and spleen. Here the foreign particles are brought into close relation with the leucocytes and an active process of phagocytosis takes place and in these

hiding places the strife between the leucocytes and bacteria is vigorously conducted. Professor ARTHUR GAMGEE concludes from his experiments that hæmoglobin is, as FARADAY stated, decidedly diamagnetic. The same is true for carbonic oxide-hæmoglobin and for methæmoglobin, whilst the iron-containing derivatives hæmatin and acethæmatin are powerfully magnetic, the difference, as he remarks, pointing to the profound transformation which occurs in the oxyhæmoglobin molecule when it is decomposed in the presence of oxygen. The experiments of Privat-docent POPIELSKI on the innervation of the pancreas show that the secretion is essentially under the control of the nerve ganglia distributed through the gland, which act in a reflex manner in cats and dogs without any participation of the central nervous system, since it continues after the ablation of the whole length of the spinal cord below the medulla oblongata and section of both vago-sympathetic nerves. Dr. F. S. LOCKE and Dr. G. F. GÖTHLIN have both succeeded in perfecting arrangements by which excised hearts can be kept beating for a considerable period. In the rabbit Dr. LOCKE preserved the heart in an active condition for one or two hours and on adding a tenth per cent. of grape sugar for no less than seven hours. The great importance of the thyroid body, formerly thought to be an almost useless appendage, is becoming constantly more obvious. Dr. A. BALDONI of Rome has experimented on the exchange of gases in dogs after its extirpation and finds that operation to be always followed by disease and death. Its removal lowers the processes of oxidation in the system to a remarkable degree. He regards it as an organ of fundamental physiological significance.

The various circumstances which may lead to the appearance of sugar in the urine have been discussed in a masterly manner by Dr. F. W. PAVY. The characters of pale or aplasmic muscles as compared with red or plasmic muscles have been studied by Dr. JOHN HAY of Liverpool, who finds that the pale muscle-fibres are larger on section than the red, less liberally supplied with blood, and possess a smaller number of nuclei. The duration of the contraction is much shorter, but is of greater height. The importance of suggestion and anticipation in the performance of muscular work has been shown by CHARLES FÉRÉ. The heat developed by muscle has been studied by MAGNUS BLIX who finds that it runs parallel with contraction.

A subject of general as well as of special physiological interest is a paper read at the Cheltenham meeting of the British Medical Association by Mr. T. S. ELLIS of Gloucester, on the Physiology of the Lower Limb and the Military March. Mr. ELLIS considers that the position of the foot taught and practised in the military march is an improper one, and that in place of it a position directed forwards, or forwards and a little inwards, should be substituted. Whether Mr. ELLIS be correct in his views or not, the subject is one that it would be well for military surgeons to reflect upon and to be guided by the light of experience. Carefully-devised experiments on several students by ZUNTZ and SCHUMBERG show that the German regulation weight to be carried by the soldier of 48 pounds approaches the limits of endurance when the distance traversed is 15 miles. The addition of a few pounds led to fall of blood-pressure, and, if the march was persisted in, to acute dilatation of the heart.

If the spermatoxic serum of the guinea-pig be injected into a male white mouse, says Mlle. C. DE LESLIE, the animal loses the capacity for reproduction for a period varying from 16 to 20 days, and if repeated the animal is sterile for another like period. The spermatozoa have lost their fertilising power without losing their motion or the animal its health. The cause of this is probably, she thinks, owing to the toxic matter fixing itself on the surface of the spermatozoa and their modifying osmotic relations.

Amongst the more important treatises on biology and the

branches of knowledge included under that term are those by the following authors: on zoology, by ADAM SEDGWICK, G. P. MUDGE, E. W. MACBRIDE and A. E. SHIPLEY, E. A. MINCHIN, G. H. FOWLER and G. C. BOURNE, and D. H. GADOW; on anatomy, by DEAYER, POIRIER, and CHARPY HEULE; on physiology, by HALLIBURTON, HALL, BUNGE, ROSENTHAL, LAULANIÉ, VERWORN, STARLING, and RAYMOND; on histology, by STÖHR, NICHOLS and VALE, LANGLEY, and GREEFF; and on embryology, by KORSCHLDT and HEIDER.

#### ANÆSTHETICS.

##### *Physiology of Anæsthesia.*

The physiology of anæsthesia, which after all must go before all improvements in technique, apparatus, and methods, has during the past year received much attention and has been enlightened by some important papers. In THE LANCET as long ago as Feb. 1st, 1896 (p. 279), attention was drawn to the importance of studying the effects of anæsthetics upon the blood corpuscles. It was pointed out that many of the results of narcotising agents are probably due to such effects. In the September number of the *Annals of Surgery* CHALMERS DA COSTA and F. J. KALTEYER contribute a careful paper upon this matter. The subject has, of course, several sides. If there is a marked destruction of red corpuscles and a diminished amount of hæmoglobin not only will the tissues suffer but there must be a distinct loss of oxygen absorption and of oxygen deportation to the nerve centres. The researches of J. LORRAIN SMITH and J. HALDANE have shown that the oxygen capacity of blood corpuscles varies within fairly wide limits and we have yet to learn how far the introduction of anæsthetics into the blood affects this oxygen capacity. Although not answering this important question DA COSTA and KALTEYER supply information which has a direct bearing upon it. They attempted as far as possible to test the various factors at work in producing blood-corpuscular changes in patients who after due preparation are operated upon and recover, and their results are interesting. They, however, give evidence in the case of only one anæsthetic—namely, ether. BIERFREUND, whose work MIKULICZ published, found a hæmoglobin destruction of from 5 to 10 per cent., and speaking of the same anæsthetic T. OLIVER and F. C. GARRETT came to the conclusion that under its influence the blood and the tissues became deoxidised, but it is not clear how far the destruction of corpuscles was in their view responsible for such a condition. They believed that the quantity of waste materials so produced constituted a danger. DA COSTA and KALTEYER in their last research, however, point out that the purgation and fasting of the patient before the anæsthetic must tend to “inspissate” the blood. They found on counting the red corpuscles in 50 cases polycythæmia, rarely oligocythæmia—due, they believe, to lessening of the total volume of the liquor sanguinis arising from pre-anæsthetic preparation and, in the case of ether, from profuse sweating during the anæsthetic stage. The concentration and departure from the normal standard of the corpuscles soon disappeared upon withdrawal of the anæsthetic. They found further—and this is a point of great practical importance—that the hæmoglobin is reduced absolutely in amount. The individual corpuscular hæmoglobin value is distinctly lessened. Thus it would appear that destruction of red cells is followed by the appearance of cells imperfectly supplied with hæmoglobin. “We must conclude,” the observers say, “that etherisation produces increased hæmolysis.” Admitting that the duration of the anæsthetic state, as well as the amount of ether inhaled, may produce blood changes, there are so many other factors at work that, as is pointed out, we are without any very exact gauge of the degree in which the duration and amount of the anæsthetic influence such changes. One factor—the method by which induction and maintenance

of anæsthesia are brought about—is omitted, the *quasi*-open plan often pursued in the United States and on the continent is certainly likely to produce different results in different hands, results hardly comparable with those consequent upon the use of closed inhalers. It is further noted that hæmorrhage did not appear to affect the blood state. This is probably explained by the fact that in DA COSTA and KALTEYER'S cases few involved severe bleeding. The outcome of this research may be of practical value to the surgeon. It is suggested that the blood should in all operation cases be examined and if the hæmoglobin is found to have fallen below 50 per cent. operation under general anæsthesia involves grave risks. HAMILTON FISH, who has worked on similar lines, confirms this view. R. C. CABOT, whose research on Clinical Examination of the Blood is well known, has also, in collaboration with Dr. J. B. BLAKE and Dr. J. C. HUBBARD, investigated the effect of anæsthetics on the blood in surgical practice and tabulated a number of cases. These observers find slight leucocytosis after complete anæsthesia is produced and, further, in half the cases a considerable increase of white cells after operation. In contravention of the statement of BIERFREUND<sup>1</sup> they found that a perfectly normal and rapid regeneration of blood-cells ensued after operations for malignant disease. It seems certain, then, that some positive effect is produced by anæsthetics upon the blood-cells; what the effects of various anæsthetics may be when compared has yet to be determined, and it is not a little important to ascertain further what changes, if any, are brought about by these bodies upon the somatic tissues. In this connexion the case recorded by J. NICOLAYSEN<sup>2</sup> may be quoted. The patient suffered for a week, after inhaling 40 grammes of chloroform, from hæmatoporphyrinuria due, NICOLAYSEN believed, to destruction of red blood corpuscles in the liver consequent upon the chloroform. A valuable contribution to our knowledge has been made by Dr. HAMILTON WRIGHT, the director of the Pathological Institute of the Federated Malay States.<sup>3</sup> He gave chloroform, and in some cases ether, to rabbits and dogs for various lengths of time under precautions as to maintenance of temperature and then studied the neurons to discover what changes, if any, were produced in the nervous system by anæsthetic agents. We can only give his conclusions briefly although they are of far-reaching importance. Rabbits, which are extremely easily affected by anæsthetics, showed distinct neuronal changes—mainly rarefactive—and these were proportional to the length of time during which the animals were subjected to the vapour. That in the most marked cases a “pseudo-degenerative” change was found is extremely interesting, as STRASBOURG, FISCHER, and THIEM have found in the case of chloroform degenerative changes in the muscular and visceral protoplasm. In rabbits, again, moniliform enlargements of the dendrons of a degenerative character were seen and the process extended in longer experiments towards the cell bodies. Dogs, on the other hand, showed no changes until after two hours and even then the changes were less marked than in the case of rabbits. Dr. WRIGHT points out that this is probably because the neurons of dogs are less affected by drugs and the inference is possibly admissible that those of human beings are still less assailable. Dr. WRIGHT makes out a strong case in favour of these changes being of a bio-chemical (nutritional) rather than of a bio-physical nature, and dismisses LUGARO'S denial that moniliform enlargements do occur by pointing out that the latter's experiments were apparently not carried on for a sufficiently long time. It should be noted that neither anæmia nor venous congestion of the nerve-tissues appears to have had any causal relation with the changes noted by Dr. WRIGHT, and, further, that these changes were more pronounced when

<sup>1</sup> Langenbeck's Archiv, vol. xli.

<sup>2</sup> Norsk. Mag. f. Lægevidensk., lxi., p. 24, January, 1901.

<sup>3</sup> Journal of Physiology, December, 1900, and April, 1901.

chloroform was employed than when ether was given. It is of considerable practical importance to observe that when the dogs were subjected to very prolonged anaesthesia (six hours) the cells rapidly developed pathological changes, the nuclei and nucleoli were affected, and the progress of such changes was much more rapid during the concluding hours of prolonged anaesthesia than during the initial period—e.g., greater between the sixth and ninth than during the first six hours. The changes noted were, however, not permanent. Even after nine hours of ether narcosis the nerve-tissue was found to have become practically normal within 48 hours. Some important work has also been done upon the effects of anaesthetics upon the mammalian heart by Dr. J. A. MACWILLIAM, but before giving his results we will draw attention to some especially interesting results obtained by Dr. T. G. BRODIE and Dr. A. E. RUSSELL illustrative of reflex cardiac inhibition. It has frequently been asserted that under chloroform and during incomplete anaesthesia strong peripheral stimulation—such as the pulling out of a tooth or dragging upon abdominal viscera and other structures—is liable to inhibit the heart, and in the case of an asthenic heart a permanent breakdown of the circulation may result. This has, of course, been denied by other observers, so that the recent work of Dr. BRODIE and Dr. RUSSELL becomes doubly important. The experiments were performed chiefly with the A.C.E. mixture, some with urethane.<sup>4</sup> It was found that electrical excitation of central ends of branches of the vagi produced inhibition. The pulmonary branches gave the most pronounced reaction. The connexion of the respiratory tract appeared to be very close with the cardio-inhibitory centre. Stimulation of the nasal mucous membrane arrested the heart, as did that of the laryngeal mucous membrane, although in the last case less reaction occurred and in that of the tracheal and bronchial mucous membrane no response was obtained. It is noteworthy that stimulation of the alveolar nerves gave a reaction as active as that of the laryngeal mucous membrane. Mechanical and chemical stimulation produced similar results. Stimulation of the pulmonary nerves also produced an effect upon the respiratory and vaso-motor centres causing arrest of breathing and fall of blood-pressure. All these effects were abolished after section of the pulmonary nerves. The practical value of this work is great, but it leaves us in doubt as to whether stimulation of the pulmonary nerves during profound anaesthesia will produce as pronounced an inhibitory effect as when the narcosis is of a lighter degree. It is commonly believed that such reflex cardiac inhibition is a danger of imperfect anaesthesia; is it also one of profound narcosis? Dr. MACWILLIAM'S researches upon the mammalian heart have been given to the profession from time to time and much importance has justly been paid to his statements that one of the constant phenomena of chloroform narcosis is a gradual dilatation of the heart. The last contribution deals with the causation of changes in the pulse-rate under chloroform and throws some light upon the query we made above in that it considers the effect of light and profound narcosis upon the vagal centre. The pulse-rate at first passes through a phase of acceleration, which is followed by one of slowing, the former rate being apparently due to diminution in the activity of the vagus centre as section of the vagi prevents its appearance. The retardation appears to be due to two causes: increased activity of the vagus centre and a slowing influence upon the heart itself, and not to changes in the respiration or blood-pressure. At a certain stage of chloroform anaesthesia the vagus centre becomes very sensitive and is prone to be affected by peripheral stimuli. This stage no doubt finds a counterpart in the chloroforming of human beings and must be of special danger. Sudden arrest of

respiratory movements leads to slowing and irregularity of the pulse. During light narcosis slowing, often slight, is followed by acceleration and marked convulsions. In deeper narcosis acceleration occurs with respiratory effort and motor excitement. In profound narcosis little change occurs at first, then retardation, but no convulsion.

#### *Local Anaesthesia.—Intra-spinal Cocainisation.*

The remarkable paper of BIER in which he detailed the effects of injecting weak solutions of cocaine into the spinal canal by means of a syringe introduced between the fourth and fifth lumbar vertebrae was followed by a long series of reports of operations performed under "Spinal Cocainisation." TUFFIER,<sup>5</sup> whose work in this direction has called forth much comment, has pursued this plan with enthusiasm if not with unqualified success. In the columns of THE LANCET<sup>6</sup> the technique of the procedure was fully set forth, and due credit was rendered to CORNING, the American physician who was the first to suggest it. But as the method has become more seriously studied its dangers have forced themselves more prominently into notice. Independently of the obvious and terrible perils of intra-spinal hæmorrhage and sepsis which the advocates of spinal cocainisation assert can be completely obviated by care, there have already been reported severe after-effects, such as vertigo, prolonged paraplegia, paralysis of the sphincters, intolerable sickness, headache, rise of temperature, and collapse, which appear to be not only grave but persistent in character. RECLUS, a warm advocate of local anaesthesia, sounded a warning at a meeting of the Academy of Medicine of Paris in March about intra-spinal cocainisation, and detailed some alarming experiences and referred to deaths reported by HUMBERT, DUMONT, JONNESCO, and KING. DUMONT'S paper<sup>7</sup> should be read in this connexion. ENGELMANN of Bonn found that eucaine not only produced the same unpleasant sequelæ as cocaine, but failed to induce analgesia, but trials with tropacocaine have in the hands of SWANN<sup>8</sup> proved more promising. MEYER has also used tropacocaine and speaks well of it. GOILAV has warned against the method in old men with senile obliterating arteritis, having met with one death and one very nearly fatal experience. A considerable number of papers have appeared in continental journals about this subject, but as they do not throw further light upon the technique or question of safety they need no special mention. An experience of HERMAN MYNTER is, however, worthy of note. Having produced analgesia by intraspinal injection he performed an extensive operation for hernia, and violent explosive vomiting commenced which caused the intestines to protrude. He speaks of "evisceration," and as the patient watched the proceeding MYNTER justly regarded the scene as a terrible one.

RICHARDSON, an American physician, reports having visited TUFFIER'S clinic. He came away deeply impressed by the skill of the surgeon and the peril of the method. He speaks of the patients being more dead than alive. HARE of Philadelphia<sup>9</sup> says: "I might say of my own observations of intra-spinal injection as an anaesthetic that it will soon be regarded as a medical curiosity." This adverse criticism is called forth by the dangers which he believes to exist in the method.

#### *General Anaesthetics.*

During a discussion before the College of Physicians of Philadelphia papers were contributed on Heart Disease and Anaesthetics in Surgery. FINNEY sums up his views by saying that he regards the dangers of anaesthetics as arising from the want of experience of the average medical man in

<sup>5</sup> L'Analgesie Chirurgicale par Voie Rachidienne, Paris, 1901.

<sup>6</sup> THE LANCET, Jan. 12th, 1901, p. 137.

<sup>7</sup> Correspondenzblatt für Schweizerische Aerzte, October, 1901.

<sup>8</sup> Centralblatt für Chirurgie.

<sup>9</sup> American Journal of the Medical Sciences, August, 1901.

<sup>4</sup> Ibid., vol. xxvi., p. 92.

making a judicious selection of the requisite anæsthetic, and lack of knowledge as to how to avoid dangers or to treat such as might arise during the anæsthesia. He urged the necessity of systematic teaching of the subject in the American colleges and the appointment of men with special knowledge to work as anæsthetists in the American hospitals. A. STENGALL'S<sup>10</sup> opinions on the subject are worthy of notice. He points out that there is evidence to show that many of the deaths of patients with heart disease which occur are due not so much to actual poisoning of the heart muscle as to its asthenic condition, rendering it unable to combat the additional strain imposed upon it during the taking of the anæsthetic and conduct of the operation. He believes that many of the post-operation deaths are due to shock to the nervous system which cause basal pneumonia, gastro-duodenal disturbances, embolism, and so on. On the same subject we must notice the remarks made by MAYO who collected a number of cases of heart disease in which anæsthetics were given. He mentioned three deaths, one from chloroform on the table, one from ether occurring some time after the operation, and one from cocaine infiltration, and institutes an instructive comparison. The views of HARE must always carry weight, and his able paper on the Safest Anæsthetic to Use in Organic Diseases of the Heart and Vessels deserves careful study.<sup>11</sup> Admitting ether to be the least dangerous in all save advanced vascular disease and even advocating its use in cases of Bright's disease, HARE very justly points out that the quantity given and the actual amount inhaled are important factors in estimating danger. He advises the employment of atropine to prevent the liability of ether to produce pulmonary complications. W. REINHARD<sup>12</sup> has also contributed a note on this use of atropine, which he injects three-quarters of an hour before giving the ether inhalation.

#### *Complications of Anæsthesia.*

While noticing the references to the complications of anæsthesia we may refer to a paper by LEWIN<sup>13</sup> in which he points out that the severe vomiting after anæsthetics is due to irritation of the endings of the vagus in the coat of the stomach and suggests anæsthetising the mucous membrane by a preliminary cocainisation followed by giving mucilage of acacia or tragacanth or Irish moss to protect the surface from irritation. Whilst on this subject we may refer to the suggestion of KUDER and others to give chloretone before chloroform or ether, with a view to obviate nausea and vomiting. PRUS'S method of heart massage in cases of chloroform poisoning was noticed in THE LANCET, but his original paper<sup>14</sup> and that of PETERSON<sup>15</sup> should be consulted.

#### *Methods.—Mixtures.*

GLEITMAN contributes a paper<sup>16</sup> advocating the use of bromide of ethyl, and WILLY MEYER, dealing with this anæsthetic, warns against its use in anæmic children. ROSENBERG, speaking from some experience, believes that even delicate children take it well, and quotes MORGANTHAU'S statement that it is less depressing than chloroform, although where it kills it does so through depression of the circulatory system. E. ADAMS<sup>17</sup> gives a favourable opinion of a chloroform (43 parts) and ether (47 parts) mixture which he states has been used extensively. He found that 40 cubic centimetres lasted for an hour. The mixture, or rather solution, introduced by SCHLEICH, and other mixtures, receive attention in a careful paper by SELBERG,<sup>18</sup> while

HENLE contributes an important communication to LANGENBECK'S *Archiv* on Post Operative Pneumonia, which deals *inter alia* with the question as to how far the anæsthetic bears a causal relation to the lung complication. R. J. PROBYN-WILLIAMS, in a communication made to the Society of Anæsthetists, discussed favourably his experience with the Wertheim mixture,<sup>19</sup> a solution of ether and chloroform similar to that devised by SCHLEICH. H. BRAUN<sup>20</sup> states that if ether is used with chloroform, the mixture of their vapours being effected by an apparatus which he describes and which is essentially a "two-bottle method," no bad effects result. The vapours are obtained as a kind of spray which enters a metal mask. The administrator can regulate the amount of chloroform that he employs and the free dilution of the ether vapour obviates, BRAUN contends, all liability to ether complications.

#### *Education in Anæsthetisation.*

Certainly the most important political event in the section of anæsthetics has been the effort which has been made to render the teaching of anæsthetics compulsory upon all medical students. THE LANCET has more than once insisted very strongly that this should be done, and DUDLEY W. BUXTON, in an address to the Society of Anæsthetists, pointed out that such a course is not only desirable but a necessity if medical men are to keep in the van of scientific knowledge of their profession. MITCHELL BANKS, in a powerful paper dealing with his long experience of anæsthetics, lays down as one of the most important means of lowering the mortality from anæsthetics the systematic teaching of the use of such agents. Although at present the General Medical Council has taken no steps to include anæsthetics in the curriculum, the Royal Colleges of Physicians of London and Surgeons of England, as mentioned in THE LANCET, have, it is understood, determined to include anæsthetics as a subject with regard to which students will be obliged to furnish evidence of their knowledge. The University of London has also recognised as teachers those anæsthetists whose lectures and demonstrations have satisfied their governing body. In the columns of THE LANCET have appeared articles dealing with the statistical inquiry which was instituted by the British Medical Association subsequently to the exhaustive report which THE LANCET itself issued. The report of the British Medical Association focussed the teaching of the various schools and furnished an additional proof of the need for systematic instruction in the use of anæsthetics.

#### MIRROR OF HOSPITAL PRACTICE.

MANY cases illustrative of the present state of hospital treatment have appeared during the past year in the columns devoted to the "Mirror of Hospital Practice."

#### *Berger's Operation.*

Complete removal of the upper extremity including the scapula and half the clavicle is an operation of the first magnitude. Its success is in great part to be attributed to the device introduced by BERGER, after whom the operation is named, of commencing by dividing the clavicle and ligaturing the subclavian artery as it lies on the first rib. This reduces the hæmorrhage to moderate proportions, and if precautions against sepsis be adopted the mortality is kept at less than 5 per cent. Mr. H. W. PAGE has contributed two cases in which this operation was performed for sarcoma of the shoulder, and so far as the operation itself was concerned both cases were successful, though one patient died later from a secondary growth.

#### *Cæsarean Section.*

The mortality from Cæsarean section in suitable cases

<sup>10</sup> *Ibid.*

<sup>20</sup> *Münchener Medicinische Wochenschrift*, May 14th, 1901.

is low, and two instances in which this operation was performed successfully by Dr. G. E. HERMAN were recorded during the year. In one case the obstruction was due to a very rickety pelvis, and in the other to a uterine fibroid which filled the pelvic cavity. We have also published a third case under the care of Dr. THOMAS OLIVER and Mr. RUTHERFORD MORISON; in this instance the operation was performed in the eighth month of pregnancy on account of extensive malignant disease of the cervix, and after the child was removed total hysterectomy followed. The operation was completely successful, both mother and child surviving.

#### *Intussusception.*

We have published several cases illustrating the value of operation in intussusception. In one case Mr. C. WHIPPLE operated on a child, two years old. In another case, under the care of Mr. C. J. SELLS, the age of the patient was four months. In the case of a patient nine months old, under the care of Mr. THOMAS BRYANT, the intussusception was double, one being retrograde. In all these cases the patients recovered, and excellent examples of the value of operation were thus afforded. Dr. W. J. MAURICE's case was that of a woman, 23 years of age, and the intussusception was apparently caused by the presence in the bowel above of numerous polypoid growths which were only discovered at the necropsy. Mr. H. W. ALLINGHAM had two successful cases in children, in both of which recovery followed laparotomy; in each he removed the vermiform appendix, partly to prevent a possible future appendicitis and partly to form adhesions so as to guard against a recurrence of the invagination. The advisability of this prolongation of an operation which in itself is productive of much shock to young children is very doubtful. Dr. ARTHUR S. UNDERHILL described a case which manifested all the signs of intussusception and yet spontaneous reduction appeared to occur and the child recovered. This must be an exceedingly rare occurrence. Mr. J. BASIL HALL had a patient with an intussusception of the sigmoid flexure caused by a malignant new growth; this he was able to excise per rectum with success.

Strangulated hernia may occur in very young children, but it must be very rare indeed to meet with an earlier case than that described by Mr. D'ARCY POWER, in which he had to perform a herniotomy in a child aged five weeks. Up to the present time less than 20 cases have been recorded in children under a month old.

#### *Surgery of the Pancreas.*

Acute hæmorrhagic pancreatitis is exceedingly rare. We have published two cases, one under the care of Mr. H. W. ALLINGHAM and the other under the care of Dr. G. B. HUNT. In both cases laparotomy was performed; in one because intestinal obstruction was suspected, and in the other because it was thought that perforation might have occurred. Both cases proved fatal. An important contribution was made by Dr. R. H. COOMBS and Mr. W. GIFFORD NASH in their account of a case of a pancreatic cyst occurring in a girl four years old. The cyst was incised and drained and the child recovered. Valuable tables of all the recorded cases of traumatic and non-traumatic cysts of the pancreas were also given.

#### *Drainage of the Ventricles.*

The severe symptoms and the almost certain fatal result of increase in the intra-ventricular pressure of the brain render any operation which offers a reasonable promise of relief deserving of careful consideration. A few years ago it was shown that in many of these cases the excessive pressure could be relieved by puncture with a probe of the roof of the fourth ventricle. Three striking examples of the value of this basal drainage have been recorded by Dr. E. DEANESLY, and in all three cases very great improvement followed.

We have published a case under the care of Dr. S. J. SHARKEY and Mr. W. H. BATTLE in which apparently a malignant growth disappeared. A man, 49 years of age, suffered from chronic intestinal obstruction and a mass was felt in the abdomen involving the sigmoid flexure. Colotomy was performed above the obstruction and for 12 months all the fæces passed through the artificial anus, but at the expiration of that period the fæces passed both per anum and by the colotomy wound, so six months later Mr. BATTLE closed the colotomy opening and the patient has completely recovered.

#### *Enucleation of a Central Tumour of Bone.*

Mr. A. MARMADUKE SHEILD had a case of tumour of the right forearm in a woman, 19 years old. It was found to be an enlargement of the radius. Mr. SHEILD incised the swelling and enucleated the growth which on microscopical examination proved to be a myxochondroma with recent sarcomatous degeneration. The cavity filled with granulation tissue and the wound healed. The desirability of enucleating such growths depends chiefly on the degree of malignancy, and in this case apparently the malignancy was slight.

#### *Tetanus.*

Tetanus neonatorum is fortunately a very rare disease, and therefore a case under the care of Mr. W. MCADAM ECCLES was well worthy of record, especially as in it the use of the anti-tetanic serum was followed by recovery. The practical utility of tetanus antitoxin is by no means so free from doubt as could be wished. To obtain good results from it it must be administered early in the disease, before the toxin has formed an indissoluble bond with the motor cells of the central nervous system.

#### *Rupture of the Aorta.*

Dr. O. J. KAUFFMANN had a case of a young man, aged 19 years, in whom a rupture, apparently spontaneous, of the aorta occurred and the patient survived the accident one week. At the necropsy it was found that there was a tear in the lower part of the thoracic aorta, but no disease of the arterial wall could be discovered.

#### *Foreign Body in the Oesophagus.*

A tooth-plate impacted in the oesophagus is often exceedingly difficult to remove, especially when it is situated near the cardiac orifice. Mr. FLAVELL EDMUNDS succeeded with some difficulty in removing a denture through a gastrotomy wound and the patient recovered rapidly and completely.

Of recent years carbolic acid has been much less frequently employed in antiseptic dressings than it was at the introduction of Listerism; therefore we more rarely see cases in which the absorption of the drug has given rise to severe symptoms. Dr. D. DOUGLAS-CRAWFORD had a case under his care in which coma came on as the result of the application of carbolic compresses preparatory to osteotomy. The coma was profound and it endured in spite of treatment for several hours. Dr. DAVID NEWMAN and Dr. HENRY RUTHERFORD described two very rare cases of dislocation of the patella. In one case the patella was displaced upwards by rotation on its horizontal axis, the articular surface looking upwards; in the other the patella was dislocated downwards, so that it was wedged between the femur and tibia with its articular surface directed downwards.

#### THE NAVAL AND MILITARY MEDICAL SERVICES.

In writing about the medical services of the army and navy it would be impossible not to begin by alluding to the great national bereavement of 1901—the death of Queen VICTORIA. Throughout Her late Majesty's long reign she had always taken the keenest interest in her soldiers and sailors, especially such of them as were sick or wounded, and Her Majesty's visits to Netley were frequent. The late Queen's last public act was significant of Her Majesty's sustained and

unfailing interest in the Services. On Jan. 1st, 1901, the Queen paid a visit to the Convalescent Home at East Cowes. Several men from South Africa were there, and on the evening of the same day members of the Royal Family from Osborne entertained them with music, both vocal and instrumental.

If we may judge from the results of the past year the public medical services have somehow fallen on bad times. The dearth of candidates for the Royal Army Medical Corps has of late years rendered any competitive examination on entrance a misnomer; the Royal Navy Medical Service apparently no longer holds out attractions, and the Indian Medical Service, which has all along been the most popular of the three services, shows a falling-off in the number of candidates. We have very regretfully to record this for many reasons and not on patriotic grounds only. It goes without saying that the public medical services should hold out many advantages and attractions to young medical men, and particularly for that class of them who are not seeking the prizes won by successful specialists in civil life, but the advantages of a certain income and pension, and for those who have some love of change, enterprise, and adventure with little or no taste for the ordinary pursuits and practice of their profession in civil life. We can only trust that in our Annus Medicus of next year we may have a much more settled and satisfactory state of affairs to place on record.

#### *Royal Navy Medical Service.*

As regard the Royal Navy Medical Service there is not very much to chronicle. In our journal of Nov. 9th last we had occasion to notice favourably the report of a naval committee dealing with a very difficult but most important subject affecting the well-being and comfort of the seamen of His Majesty's navy—namely, that of rations in times of peace and war. The circumstances connected with the question of titular naval rank differ very materially from those of the Army Medical Service, and naval medical officers are apparently quite content with their present titles; but there are, nevertheless, several matters which claim further consideration with a view to their being remedied. To enumerate some of these, naval surgeons have been asking that some change should be made in the matter of improved cabin accommodation, in the shortening of the period of service qualifying for promotion to the rank of staff surgeon, in the establishment of a definite sea roster, in the more general application of promotion by selection, and in increased opportunities for study leave. Whatever changes and concessions are about to be made for army surgeons will have to be extended, as far as is suitable and practicable, to the medical officers of the navy. The competition for commissions in the Royal Navy Medical Service has been steadily falling off of late.

#### *The Indian Medical Service.*

The officers of the Indian Medical Service have had very hard work and but little leave during the past year owing to the presence of plague and famine in India, and a military expedition to China—to say nothing of any troops sent to South Africa. A state of high pressure of this kind could hardly be prolonged indefinitely, however willing medical officers might be to meet the requirements of the Indian Government under such circumstances, and it became absolutely necessary to make some arrangements in the way of an increase to the establishment. We endeavoured to embody these facts and to state the provision that was needed in these respects in a leading article on the Indian Medical Service, to which we may refer our readers.<sup>1</sup>

#### *Professional Opportunities of Members of the Indian Medical Service: their Scientific Work.*

The officers of the Indian Medical Service enjoy greater

opportunities for the practice of their profession than do their *confrères* of the Royal Army Medical Corps by virtue of the hospital and civil appointments open to them. They also do much work of a medical and scientific nature, as may be seen by the periodical publication of "Scientific Memoirs," edited by the Director-General of their service, and in the excellent annual reports drawn up in the office of the Sanitary Commissioner with the Government of India—both of which we have had occasion to notice. A good deal of "talk" has taken place as usual about the amalgamation of the services, as well as about increasing the strength of the Indian Medical Service, and handing over to it the medical charge of European troops serving in that country, but nothing has been done.

#### *The Royal Army Medical Corps and the War.*

The year that has nearly passed has been fraught with important events as regards the military medical services in connexion with the war which has been, and still is being, carried on in South Africa. It will be remembered that in 1900, in consequence of the appearance of Mr. BURDETT-COUTTS's letter in the *Times* and of the allegations which had been made as to the deplorable state of the hospital arrangements, a Royal Commission was appointed to consider and to report upon the care and treatment of the sick and wounded during the South African campaign, and that the Commissioners went out to the seat of war and after a long and laborious investigation made their report on the South African Hospitals, which was published in the beginning of the year. The report, which was unanimously signed and accepted by the Commissioners, consisted of over 70 pages and its publication was accompanied by the minutes of evidence and an appendix printed in separate volumes. While the Commissioners pointed out in what respects and to what extent the complaints with regard to the sick and wounded were well founded, and forcibly drew attention to the existence of some serious evils which called for remedy, they nevertheless concluded their report by stating that in their judgment and reviewing the campaign as a whole it had not been one where it could be properly said that the medical and hospital arrangements had broken down. "There has been nothing in the nature of a scandal with regard to the care of the sick and wounded; no general or widespread neglect of patients or indifference to their suffering. And all witnesses of experience in other wars are practically unanimous in the view that, taking it all in all, in no campaign have the sick and wounded been so well looked after as they have been in this." The report was generally accepted as an eminently just and fair report. It soon became, however, the subject of great contention and of the severest criticism on the part of Mr. BURDETT-COUTTS and others. We went very fully into the matter at the time in reviewing the report and the minutes of evidence in a series of articles published in our pages, and we have no desire to re-open the question now. But there are, nevertheless, a few radical points to which we may very briefly refer.

To begin with, it is universally admitted that neither the Government nor anyone else had any idea that the war was to become what it has turned out to be or that it would ever reach the proportions which it has. The Director-General of the Army Medical Service had only to provide for the force to be sent out, which was done on a very ample scale. He had no authority to go beyond this. So long as the military operations were confined to Natal and available lines of railway all went well with the Army Medical Service, notwithstanding that large augmentations to the army were taking place—indeed, infinitely better with the medical than with any other branch of the service. But it stands to reason that it was a very different matter when the British force became an army

<sup>1</sup> THE LANCET, March 30th, 1901, p. 948.

of over 200,000 and the principal scene of the operations was translated elsewhere and such operations had to be very rapidly conducted under totally altered conditions. Again, on the occasion of the sudden and unforeseen disastrous epidemic of enteric fever, with the admittedly deplorable state of the hospitals for the time being at Bloemfontein, we confess that we have never quite understood why Lord ROBERTS did not speak more emphatically and authoritatively as to the exact situation in which his army was placed and assume all the responsibility of what was unavoidable under the circumstances. A soldier is useless without food and ammunition, and so conditioned the safety of the whole force—sick and well—would have been jeopardised. A commander-in-chief was amply justified, therefore, in sacrificing everything to procure what was for the time being absolutely essential—indeed, would have been blameable had he not done so. Instead of eulogising the efforts which the medical officers made—which Lord ROBERTS did emphatically enough—it would have been more to the point if he had assumed the responsibility of what was, as it seems to us and as we have said, unavoidable under the circumstances. In the case of an application having been made to him for his opinion as to whether the risk of a great loss of life should be incurred for the relief of Ladysmith Lord ROBERTS—to his infinite credit be it said—did not hesitate to give an opinion such as, the nation trusts, will always be given by a general under similar circumstances. At a time of extreme military urgency, when all available transport was taken up in supplying the troops (on half rations) with food, ammunition, and stores, some of the hospitals found themselves unexpectedly overwhelmed with sick and wounded, and unquestionably much suffering was the consequence. We have not simply sought to shelter the Army Medical Service from any blame in this matter, but it has never been made clear to us that that service was really more responsible for this than for the capture of the Bloemfontein waterworks, which, together with the conditions encountered at Paardeberg, probably brought about the epidemic outbreak of enteric fever. It is, as we all know, easy to be wise after the event, but a general hospital at Orange River—could its importance have been foreseen and could arrangements have been made for its establishment there—might possibly have met the strain and saved the situation. It was not, as it seems to us, so much, however, that the hospital accommodation and provision proved quite inadequate to meet the requirements of an overwhelming number of sick which had to be accounted for as the question whether any, and what, sanitary measures could have been taken to have guarded against the calamity. Was everything done to secure a better water-supply for the troops and to keep them from occupying fouled sites and camps? The whole subject—and a most difficult one it is—of practical army sanitation in the field requires to be gone into.

#### *Enteric Fever.*

Here we may parenthetically remark that, as we all know, enteric fever has proved a veritable scourge to our troops in South Africa, and that, in addition to the disastrous outbreak to which we have just been referring, the prevalence of that disease has been so widespread as to be well-nigh continuous with the presence of the British troops who have apparently suffered from it to a very much greater extent than have the Boers. As our readers are aware Dr. H. E. LEIGH CANNEY, in a notable lecture which he recently delivered at the Royal United Service Institution, has made a practical proposal for the prevention of army diseases in war—so far as these are water-borne diseases—with which we have already dealt in a leading article.<sup>2</sup>

#### *Report of Mr. Brodrick's Committee.*

But to resume the thread of our history of the Army

Medical Service. It followed upon the publication of the report of the Royal Commission on the South African Hospitals that things could not remain as they were and Mr. BRODRICK made a bold attempt at the reform and reorganisation of the Army Medical Services. A War Office Committee was appointed, consisting mainly of experts, several of whom had had recent personal experience at the seat of war, and presided over by the War Minister himself. In due time it made its report. That Mr. BRODRICK was sincerely desirous of so remodeling and improving the existing Army Medical Services and of making them, as he had said, the best in the world, we have been assured and have no doubt. But the result, so far as the report of the committee is concerned, has, we regret to say, been very disappointing. Truly, it is but a report and it has served a very useful purpose in that it has been freely criticised and its defects and shortcomings have been pointed out in time for them to be remedied and for the re-casting of a scheme at present merely outlined before it is embodied and carried into effect in a Royal Warrant. It is not that there is not a good deal which is excellent in design and good in itself in the report, for there undoubtedly is. The bare facts that the scheme seeks to shut the door on seniority as the main qualification and to open the way to promotion by selection, and that it makes an earnest attempt to raise the professional and scientific standard of the medical officers, are in themselves of great value. The profession is honestly desirous of seeing an end to long-standing and recurring controversies by the public medical services being made attractive and popular with the class of young medical men whom we all desire to see in them; but the War Office scheme as foreshadowed in the report will not, we fear, do this. A great initial mistake was made in not having appointed an experienced army medical officer of high rank on the committee. Then, again, we venture to think that if some of the proposals had been adopted which we put forward in the series of articles which appeared in THE LANCET consequent on the publication of the report of the Royal Commission on the South African Hospitals during February, March, and April<sup>3</sup> several rocks and shoals would have been avoided without any sacrifice of the aim, spirit, and intention underlying the report of Mr. BRODRICK's Committee.

#### *Changes required in the New Reorganisation Scheme.*

Be this as it may, several changes will have to be made in the new scheme of army medical reform in regard to the number of examinations required and their supposed value as tests of fitness and merit, in the clearing up of the uncertainty that exists as to the terms on which an officer may retire or be retired compulsorily at different periods of his service, to say nothing of other matters which seem to call for very careful consideration before being finally adopted. Assuming, however, that the War Minister is earnestly bent upon attaining the object which he has in view, and there being, as we have said, no finality about the report, we see no reason why Mr. BRODRICK should not reconsider the subject and, while retaining all that is good and desirable in his scheme, reconstruct it where necessary. As regards a number of important measures and matters of detail which will in any case have to be considered—such as those separately put on record by Professor A. OGSTON in his addendum to the report of Mr. BRODRICK's Committee—these can be hereafter taken up and discussed by the Advisory Board and by the newly-appointed Director-General and by the War Office Council and Army Board, of which he is a member. Surgeon-General W. TAYLOR will, at any rate, no longer have to complain, as his predecessor Surgeon-General J. JAMESON had to do, that matters relating to his department had been discussed and decided upon at War Office conferences in his absence.

<sup>2</sup> THE LANCET, Nov. 30th, 1901, p. 1507.

<sup>3</sup> See THE LANCET, April 27th, 1901, p. 1224.

*The Strain of the War.*

The strain put upon the medical department by this war has been such as it has never had to bear before. The whole of the establishment was expended during the earlier months of the war, and events developed so rapidly that the army was first doubled and then increased threefold or even fourfold. Up to June last 50,000 invalids had been received and dealt with in this country from South Africa, India, and the colonies since the beginning of the war, and at that time there were 21,000 beds equipped in South Africa, exclusive of the field hospitals. Nor must it be forgotten that the country owes a deep debt of gratitude to all who organised and equipped the large and numerous private hospitals sent out to the seat of war.

*The Complimentary Dinner to the late Director-General of the Army Medical Service.*

The work and responsibility imposed upon the Director-General and his staff must have been enormous, and it was therefore with surprise and regret that the profession learned that Surgeon-General JAMESON was relinquishing his office of Director-General and that he was allowed to leave the army without the customary recognition of his services being accorded to him by the Government. A large and representative gathering of the profession—who were at a loss to understand the circumstances and who strongly sympathised with the retired officer—took place on the occasion of a complimentary dinner being given to him.<sup>4</sup>

*War Literature.*

The thought which has in reality been uppermost in men's minds during the past year, although it may not have been apparent, has naturally been the war, and the literature about it is so voluminous that it forms a library in itself. Much of it is, of course, of an ephemeral, and some of a conflicting and contentious, nature, especially in regard to the organisation, efficiency, and working of the army medical services in the field. It is but fair to recollect that in this, as in all other things not as plain as the multiplication table, the tendency is for writers to see what it is in their minds to see, rather than to describe and to weigh the facts impartially and in their due relationship to one another. Speaking for ourselves we have no sympathy with that class of carping critics who, whilst neither incurring nor sharing in any personal responsibility themselves, are only too ready to impute blame or to find fault with the doings of others. For all that the detractors of the corps may say they are not likely to make the profession or the public believe that the officers and men of the Royal Army Medical Corps have not shown great courage and devotion and done splendid work in this South African war. When the conclusions range within the extreme limits of increasing the strength and developing a permanent military medical service so as to maintain it always fit for war on the one hand, and reach the opposite extreme, on the other hand, of well-nigh, if not quite, abolishing it altogether, it is, to say the least, a difficult and embarrassing problem for the Government to solve.

As regards the strictly professional works that have appeared we must not forget to mention that by Mr. G. H. MAKINS<sup>5</sup> and that by the professional staff of the Portland Hospital—both admirable in their way. Mr. MAKINS's valuable book and Mr. A. A. BOWLBY's contributions to the surgery of the war have really added to our knowledge of gunshot wounds and military surgery. Nor should it be forgotten that the late Sir WILLIAM MAC CORMAC, whose recent death we are all, and not least so army surgeons in this country and abroad, deploring at the present time, was among the first to contribute to our columns a series of most interesting articles on the surgery and hospitals of the war. What

rendered Sir WILLIAM MAC CORMAC's writings so valuable at the time of their publication was that he was able to compare his experience in South Africa with that which he had previously obtained in the Franco-German war and elsewhere. The contrast was striking and indeed marvellous, owing to the use of quick-firing, long-range rifled weapons and small projectiles and the employment of the antiseptic system of treating wounds. So striking was the difference that it fully accounts for Sir WILLIAM MAC CORMAC having adopted a far more optimistic tone in describing the results of the gunshot wounds he saw in South Africa. At Sedan the mortality following gunshot injuries and amputations from pyæmia and infection wound diseases alone was enormous. In these and other respects what a revolution has taken place in regard to the surgical practice of this present war.

**CHEMISTRY.***Radio-Activity.*

That curious and remarkable property possessed by certain substances and known as "radio-activity" has been further studied during the past year with results, it may be, of the highest possible significance. In recording the work of research in this particular field last year we took occasion to say that "it is evident that chemists are on the threshold of an entirely new field of research which promises to yield very remarkable results." It would indeed be a remarkable result if the discovery of this property of radio-activity proved to lead to a readjustment of the atomic weights. It is pretty certain, at any rate, that this property does betray the presence of an impurity in a substance which was previously regarded as pure, or the presence of another element in the substance previously regarded as elementary. If so we may reasonably entertain some doubt as to the accuracy of atomic weight determinations owing to the presence of minute quantities of unknown elements in what was regarded as the virginal substance. As is well known the atomic weights of the 70 odd elements differ only by a small amount from whole numbers. Possibly this small difference may ultimately be eliminated by the discovery that pure elementary material has not been the starting point. Thus radio-activity may establish that after all PROUT was right in his remarkable hypothesis that the atomic weights of the elements are multiples by whole numbers of the atomic weight of hydrogen and the question may therefore be nearer settlement as to whether the elements have had a common origin or whether they may not represent several stages in an evolutionary process operating upon a primitive simple material, and whether in that case it may not be possible to transform one into another by the operation of agencies within the range of practicable experiments. The study of radio-activity is thus reviving the possibility of the transmutation of the elements, and once again alchemy and modern chemistry "kiss each other." There can be little doubt, at any rate, of the existence of a large number of undiscovered elements, and it is probable that many of them will be found to be similar to elements and to such an extent that they may now exist unsuspected with the known elements and may affect their atomic weights to the fractional extent that has seemed to disprove PROUT's whole-number hypothesis. Radio-activity is not only a property of solids but of liquids and gases also. Thus water can be rendered radio-active by distilling it from a solution of radium chloride in an absolutely air-tight vessel. That the property is remarkably communicable is shown by the fact that when a vessel of distilled water is connected with a vessel containing radium chloride the water soon becomes radio-active, the radio-activity having been communicated by the gas in the closed vessel. Radium rays cause skin wounds as do Roentgen rays and have similar physiological effects. The development of this fascinating field of research will be eagerly watched.

<sup>4</sup> THE LANCET, July 27th, 1901, p. 247.

<sup>5</sup> Surgical Experiences in South Africa, 1899-1900. Smith, Elder and Co.

**Radiant phenomena** have also been studied in connexion with the phosphorescence of many substances. The cause of the so-called "phosphorescence" to be seen at times on such objects as dead fish is found to be due to a luminous bacterium belonging to a group of organisms whose natural habitat is sea water. Their luminous properties are dependent on a supply of free oxygen and a suitable percentage of a soluble chloride in a nutritive medium. Artificial cultivations may readily be made and the experiment is attended with very beautiful results in which the effect of oxygen on the phosphorescence of the culture can be easily observed.

#### *New Gases in the Atmosphere.*

Professor DEWAR has been very busy on the separation of the least volatile gases of the air and the results are wonderful in bringing to light the fact of the presence of many more gaseous elements in the air than our philosophy ever dreamt of. Thus there are hydrogen, helium, neon, krypton, xenon, and doubtless others, their separation being effected by the excessively low temperatures employed by Professor DEWAR in his liquid air apparatus. By and by, perhaps, we shall reach the zero of temperature, but there are enormous difficulties in the way. Even liquid helium with a probable boiling point of five degrees would not assist the inquiry very much. A gas must be found much more volatile than helium is in relation to hydrogen, in order to reach within one degree of the zero of temperature. But to start with the production of liquid helium is a problem difficult and expensive enough to occupy the scientific world for many a day. Apart from the indications of new elements the actual discovery of a new one during the year has not been announced, with perhaps one exception. This is in regard to europium which appears to be related to the rare elements isolated by CROOKES, their characteristic being a brilliant phosphorescent spectrum.

#### *Lipase.*

Some very remarkable results have been obtained in connexion with an investigation of lipase, the fat-splitting enzyme. As is well known "lipase" is the name now given to that enzyme which is associated with trypsin. It is agreed to call it "lipase" and neither "pialyn" nor "steapsin" as formerly. Lipase acts by hydrolysing fats—that is, separating them into fatty acid and glycerine. It has now been shown that its action is reversible—the reaction ceasing when the products of the hydrolysis reach a definite concentration in consequence of equilibrium being established. Thus it may effect either analysis or synthesis, as has been shown by its action upon ethyl butyrate, which is a chemical analogue of fat. Lipase would appear to be present in the liver, stomach, and small intestines. It is a stable enzyme but easily acted upon by heat and by antiseptics.

#### *The Nature of Ammonium.*

Every chemical student remembers the remarkable result which is obtained when sodium amalgam is treated with strong ammonium chloride solution. An interaction takes place and a huge buttery mass with a metallic appearance is evolved which by some has been regarded as a true amalgam of ammonium, thus establishing the metallic character of the  $\text{NH}_4$  group. On the other hand, experimental evidence has been adduced which is apparently not in favour of this view. In a recent series of experiments, however, very unmistakable evidence of the metallic nature of ammonium was obtained. The ammonium amalgam was prepared by an electrolytic method and when it was brought into a solution of a copper salt copper amalgam readily formed which in its turn yielded copper on the battery plate.

#### *A Test for Human Blood.*

The action of peroxide of hydrogen on the blood has been studied with the result that a comparatively easy means of

distinguishing human blood from that of animals has been brought to light. Human blood has a much stronger decomposing action on peroxide of hydrogen than that of animals, the volume of oxygen gas given off being more than four times the amount than in the case of bullock's blood and ten times greater than with sheep's blood.

#### *Analyses, Chemical and Spectrographic.*

Some interesting results of analysis have been published during the year of gold foil from the Royal Tombs of the First Dynasty. The gold used by the ancient Egyptians was undoubtedly the native alloy and it is generally found to contain silver. Some of the foil is much tarnished which is due to the formation of chloride of silver, an explanation which affords an interesting instance of the slow diffusion of one part of the alloy (the silver) till it reaches the outside surface where it meets with the chlorides that exist in the sands of the desert.

Spectrographic analysis has brought to light an extraordinary number of mineral constituents in dust and soot from various sources. In the dust appearing in hail, snow, or sleet iron, nickel, calcium, copper, potassium, and sodium have been found. In volcanic dust the chief constituents were lime, magnesia, and the alkalis; in soot from different chimneys nickel, calcium, manganese, copper, and silver were detected; in flue-dust lead, silver, copper, and manganese were found besides the comparatively rare metals rubidium, galenium, indium, and thallium. It will thus be realised that the spectroscope is not confined in its usefulness to the examination of solar or stellar phenomena. It has recently, however, revealed a wealth of results in regard to the chemistry of the sun. The last list of elements occurring in the sun which Sir NORMAN LOCKYER has furnished to the Royal Society was based on the observations made on the total eclipse of the sun on Jan. 22nd, 1898, at Viziadrag. This investigation showed the probable presence of calcium, chromium, iron, manganese, nickel, strontium, titanium, cobalt, copper, indium, lead, molybdenum, potassium, rubidium, aluminium, barium, carbon, magnesium, sodium, scandium, cerium, lanthanum, lithium, rhodium, tantalum, vanadium, bismuth, caesium, gold, ruthenium, selenium, silicon, thallium, tin, tungsten, yttrium, zinc, zirconium, and hydrogen, helium, and asterium. There are missing from this list antimony, arsenic, cadmium, iridium, mercury, osmium, palladium, platinum, silver, and thorium, of the presence of which no evidence was gained. Truly the chemist has a wide and a far-off field within his ken for investigation and study.

#### **PUBLIC HEALTH.**

It may be said of the year now past that it has, in a public health sense, been fuller in potentialities than in actualities. Nevertheless, some good work stands to its credit.

#### *The Numbering of the People.*

From the public health standpoint the census of 1901 was an all-important event. Without such periodical reckonings of our gains and losses vital statistics would possess relatively little value, and even with a decennial enumeration the inaccuracies which are apt to creep in towards the end of the decade render it necessary that the rates based upon the estimates shall be received with the greatest caution. The census figures are, perhaps, more encouraging than was expected, but, nevertheless, the indications are not altogether reassuring as regards the maintenance of the population by means of the excess of births over deaths; the balance of immigration over emigration is another matter. Although the rate of increase for the decade amounted to 12.17 per cent., as against an increase of 11.65 per cent. in the previous decade, and although the increase is numerically in excess of that recorded previously, we are face to face with the fact that the percentage-rate of increase was less than that

for any decade during the last century, save those ending in 1861 and in 1891. The natural increase per cent. was 12·39, as compared with 13·97 in the previous decade. Although the mean annual death-rate has steadily declined since 1861-71, the important fact remains that the birth-rate has declined still more rapidly since 1871-81. The percentage of increase or decrease in the several large towns varied enormously. In East Ham the increase was no less than 193·44 per cent., while in Huddersfield there was a decrease of 0·43 per cent. But in considering the figures as regards the large towns questions as to borough extension or the exodus of the population to the suburbs have to be borne in mind.

#### *Tuberculosis.*

The year 1901 will loom large in the annals of tuberculosis with respect to the question of its control in so far as Great Britain, and, indeed, the empire as a whole, is concerned. The congress which assembled in London in the summer has had as one of its results a quickening effect upon the appreciation of the profession and of the public of the importance of preventive measures—of more light, more air, greater cleanliness, and less promiscuous expectoration. The keener recognition of the value of all these agencies may reasonably be held to have an effect, not only upon the prevalence of tuberculosis, but also in diminishing the opportunities of spread of other communicable diseases. In the direction of the promotion of sanatoriums for the open-air treatment of phthisis several schemes have been recently set on foot, and in this sense the potentialities of the congress of 1901 are full of promise, in that the meetings tended to bring home to the public the great superiority of the Germans in the matter of sanatoriums for the working-classes. The State insurance laws in Germany render it essential that all workmen receiving not more than £100 per annum shall be insured against sickness and old age, and it is from the funds of these insurances that sanatoriums are largely supported.

#### *The Relation of Bovine to Human Tuberculosis.*

The remarkable address of Professor KOCH at the Tuberculosis Congress in which he practically denied the communicability of bovine tuberculosis to man, albeit he furnished in support of his thesis only a series of experiments pointing to the difficulty of communicating human tuberculosis to bovines, has led to the appointment of a Royal Commission to control both the experiments and the inferences therefrom. We are afraid that it may be difficult exactly to copy in the laboratory or even on the farm that which takes place in everyday life, as the feeding of children with tuberculous milk or meat is hardly within the realms of practicability. It has to be borne in mind that the problem is really not only as to whether bovine tuberculosis can be conveyed to the human species, but if so, with what degree of facility and through what channels it may be thus conveyed. There are, however, indications from work since done in Holland and elsewhere that Professor KOCH's conclusions were premature, and it behoves all sanitary authorities not to relax their efforts for the control of tuberculous milk and meat.

#### *Food Preservatives.*

The committee appointed to consider the important subject of the preservation by chemicals of foods and drinks issued their report toward the close of the year, and we have recently dealt fully with it in our columns, where we expressed our cordial concurrence with the general tenor of the recommendations. It is to be hoped that the Government will at an early date bring in a Bill dealing with the recommendations of the committee. The members of that committee have clearly seen the need for a more thorough control of our food supply, and they have accentuated the importance of setting up some machinery by means of which the repeated formation of Royal Commissions or Departmental Committees

may in the future be rendered unnecessary. They advise the formation of a Board of Reference to which questions affecting the safety or otherwise of new or existing preservatives or colouring matters might be referred. Indeed, it is obvious that some such court of reference as this would find ample matter wherewith to occupy its time. Whatever form this body may ultimately take, there can be no doubt that at present the control of the manufacture and preparation of foodstuffs and drinks is sadly in need of improvement. All places where these substances are prepared should be subjected to periodical inspection, and in this manner chemists and the bacteriologists might receive very considerable assistance in their work. The President of the Local Government Board is a strong and independent administrator, and an opportunity is now afforded to him of materially improving the control of our foods and drinks. The methods adopted by the French Consulting Committee of Hygiene or by the Gesundheitsamte of Germany might be usefully studied.

#### *Plague in 1901.*

During 1901 plague has fully maintained its hold upon the four quarters of the globe. The largest incidence has, as before, been among the teeming millions of India where the disease has spread to new localities and bids fair to repeat in Bengal the ravages it has caused in the Bombay Presidency in past years. In China, too, plague has not relaxed its virulence, Hong-Kong having again passed through a severe epidemic. Other places, such as Canton and Amoy, have also suffered. Japan, with its large shipping connexion, has, like other maritime nations, suffered from imported infection. In Formosa, again, the victims have numbered thousands. In the Philippine Group Manila has been the chief sufferer, while in less amount the Straits Settlements, Queensland, New Caledonia, and the Sandwich Islands have again been visited by the disease. At San Francisco, notwithstanding emphatic denials to the contrary, plague has smouldered on in the Chinese quarter. In Argentina and in Brazil there have been fresh outbreaks. South Africa has had a sharp outburst, confined largely to the Cape Peninsula, but ultimately reaching Port Elizabeth. The disease once again broke out in Mauritius in epidemic form and on a smaller scale in Réunion. Towards the end of the year the district behind Delagoa Bay was reported to be once more infected. In Egypt the annual recrudescence of plague was not confined to Alexandria and Port Said, but appeared in a number of distant inland localities where, fortunately, it was soon checked. In Arabia, more especially in Assyr, plague again showed itself. In various seaport towns in the Levant scattered cases were reported, but larger groups appeared in the Smyrna port and district, as well as in Constantinople, and later in certain Turkish ports in the Black Sea. The Russian ports of Batoum and Odessa yielded cases, as also did Naples, but in each instance the outbreaks are reported to have been promptly suppressed. At Marseilles there have been a comparatively large number of ship-borne cases, a group of 22 occurring in connexion with a single vessel and six in another, while smaller groups of cases were reported, especially during the latter part of the year, on board vessels arriving from the East. So far as is known no inland cases have occurred in France.

England has not escaped from ship-borne infection. At Hull a group of nine cases, eight of them fatal, occurred early in the year in connexion with the s.s. *Priary* from Alexandria. Fortunately the disease was promptly dealt with and there was no extension. In another vessel which arrived at Bristol from Smyrna, an infected port, rats were found to be suffering from plague, but no case in man was discovered. In another ship which arrived at Southampton from South Africa a single case of plague in an Asiatic member of the crew was discovered. It is worthy of notice that up to the

beginning of December no fewer than 23 other vessels had been reported on arrival to have on board cases suspicious of plague. But in none of them was the diagnosis confirmed by bacteriological investigation. During 1901 there were two instances in which inland plague was recognised and the origin of which was in doubt. At Cardiff at the end of January a fatal case of plague, bacterioscopically confirmed, was reported, and later a second case in which, however, the bacteriologist was unable to confirm the diagnosis. At the same time it was found that rats at a mill where the first victim had worked were also suffering from the disease. Fortunately there was no extension of the disease and so far as is known Cardiff remained free from plague during the rest of the year. During October a group of cases occurred at Liverpool in which there was bacteriological evidence to prove the existence in one or more of them of true plague. It is now believed that nine persons had suffered from the disease, of whom five died. The cases were at first thought to be due to a severe form of influenza. There was no evidence of infection by means of rats and the outbreak quickly came to a termination under the active measures carried out by the health authorities. In the autumn two groups of cases occurred at Glasgow: the first comprised five persons, three of whom died; the second group, also including five sufferers, one of whom succumbed, appeared a month later, apparently having no connexion with the first. Of this last group only one case was fatal, but it was found that rats in the basement of the building, where all of the five persons were employed, were also suffering from plague. Here, again, the outbreak was soon suppressed and no fresh cases were reported up to the middle of December. Although, therefore, the past year has brought us no epidemic of plague, it cannot be said that the experience of the 12 months is precisely reassuring. The abundant and increasing evidence connecting human plague with a similar disease in certain rodents and the very material difficulty in controlling the movements of such rodents make us somewhat sceptical as to whether our present measures are all-sufficient. The Port of London has recently set an excellent example by adopting regulations with respect to the berthing of ships, which are already practised, we believe, in certain of our colonies, and other ports will, it is to be hoped, follow. The outbreaks of plague at Liverpool and at Glasgow, which, strangely enough, were of almost simultaneous occurrence, have served to show us that, in spite of all our seaboard precautions, plague may reach us in a manner which cannot be traced, and that with a relatively unprotected Scotch and Irish seaboard we may be in need of a more uniform administration of all the ports of Great Britain.

#### *Small-pox and Vaccination.*

In London, at least, small-pox and, as a consequence, vaccinia have been prevalent during 1901, and although the number of cases of small-pox cannot be said to constitute an epidemic, the disease is persisting with a pertinacity which must cause some anxiety to those at all familiar with the natural history of variola, more particularly so when it is remembered that the greatest seasonal prevalence of the disease is in the first half of the year. The outbreak has served to bring out certain salient points. In the first place, we are able to see what a large proportion of small-pox may be traced to importation from abroad, and in the second place it has brought home to us the fact that the *unrecognised case* is an enormous factor in maintaining the prevalence of the disease. Unfortunately there are no means at our disposal of recognising a person who is incubating small-pox, or for the matter of that any other infectious disease, but the general notification of varicella would tend materially to control the unrecognised channels through which small-pox now spreads, and there would seem to be no very strong

objection to adding this disease to the notifiable diseases. Although of itself varicella is hardly a dangerous disease, it is so by virtue of the frequency with which mild cases of variola are liable to be ranked as varicella. With regard to vaccination it may be said that the present law has worked smoothly during the year and the general testimony of the country as a whole is favourable to its provisions. Unless, however, revaccination can be put upon the same basis as primary vaccination small-pox will never be reduced to its smallest practicable limits and the medical profession should lose no opportunity of enforcing this truth upon our legislators and upon the public. The more modern methods of performing vaccination are, we are in a position to state, being gratefully appreciated by the people who in these days are becoming alive to the necessity for asepticism in anything approaching a surgical operation. So, too, the greater care which is now taken in the preparation of calf lymph is a matter for congratulation. The outstanding dangers to be anticipated and to be guarded against are inert lymph and one-mark vaccination; both of these will tend to bring vaccination into disrepute when the variolous test is applied. The former danger is one for our bacteriologists and for our dispensers of lymph, the latter for the conscience of the medical profession.

#### *Isolation Hospitals.*

Although steady progress has been made during the year in the provision of isolation hospitals, both for the ordinary infectious diseases and for small-pox, it is not unlikely that the Isolation Hospitals Act of 1901 may prove instrumental in bringing about a somewhat wholesale provision of these indispensable institutions. In the detailed management of many isolation hospitals there is doubtless room for improvement, but as to their general utility there can, we think, be no question, and the opportunity afforded to county councils is one which the more progressive counties will not be slow to take advantage of. All isolation hospitals can now, with the consent of the Local Government Board, be transferred to the county councils, and by the provisions of the same Act these bodies may make substantial contributions to the erection and maintenance of such hospitals.

#### *The Disposal of Sewage.*

The Royal Commission appointed to inquire into the treatment and disposal of sewage is still sitting, and as far as we are able to gather there is no immediate prospect of the completion of its labours. It was probably this feeling that induced the Commission to issue an interim report, the effect of which is, we take it, likely to induce the Local Government Board to modify their demands for the provision of land in every case. It would seem, too, as if the chances of entirely getting rid of pathogenic organisms by any of the methods of treatment at present in vogue are remote and it may be that the Commission will find it necessary to recommend that in some cases, where, for instance, effluents are to pass into the water-courses used for drinking purposes, or into estuaries near to oyster-fattening beds, some form of sterilisation should be adopted. But even then it will be found difficult to sterilise the surface washings of the adjoining catchment area, and the bacteriologist may still look askance at the waters of the river. Doubtless, however, the requirements will have to be modified to meet the particular needs of individual cases, and it is hardly likely, save perhaps in cases where shell-fish industries are concerned, that an effluent of a very high degree of bacterial purity will be asked for where discharge directly into the sea is in question.

#### *The Prevention of Enteric Fever among Armies in the Field.*

The lessening of the ravages of enteric fever during war is a public health question of no small importance; indeed, war generally is very much an enemy to the public health in that it tends to kill off in one or another fashion the

physically fit and leaves the relatively weakly at home to continue the race. It is, therefore, a matter of the greatest moment that a reasonable trial should be given to those suggestions for the sterilisation of drinking-water which have recently been made by Dr. H. E. LEIGH CANNEY and others, whether by boiling or by chemical means. Doubtless there are under camp conditions channels for the spread of enteric fever otherwise than by water, but if a supply of sterilised water can be provided for troops in the field one great agency of spread will have been controlled. The cost of testing the several proposals which have been made would in times of peace be practically *nil*. The Commissioners who were appointed to inquire into enteric fever and dysentery and who left England in the summer of 1900 may, we hope, render valuable assistance in their report which, we understand, has already been presented to the Secretary of State for War.

#### *The Royal Commission on Arsenical Poisoning.*

The first report of this Commission which was published in the summer did not add much to the knowledge which was already before the world as to the cause of the remarkable outbreak of arsenical poisoning, but it placed as it were a sort of authoritative stamp upon the reports which had already been issued upon the subject. This Commission is now ascertaining by means of all the channels at its disposal in what manner the risks such as are here in question can be prevented in the future, not only in respect of beer, but of foods and drinks generally. It will be interesting to find what recommendations in respect of the improvement of our present machinery for the better control of foods are made in the final report, and if the provisional recommendation embodied in the first report by the majority of the commissioners is adhered to an instructive report may certainly be anticipated.

#### *The Abolition of Smoke.*

The Londoner is long-suffering in the matter of fog and smoke, but he nevertheless welcomes any efforts or movements which are likely to render the London fog less opaque. The year 1901 has at least not been barren in this respect, and if the efforts which are now being made are supported by the metropolitan boroughs and by the London County Council the nearly absolute darkness of the recent fogs may become in time a matter of history only.

#### *The Housing of the Working-classes and the Poor.*

In the matter of information as to the housing of the working-classes the year 1901 has been somewhat prolific. The London County Council has issued "The Housing Question in London"—a volume which contains a most useful account of what has been done in the metropolis in the past in connexion with this extremely complicated problem, and we have already noticed the work at considerable length in our columns.<sup>1</sup> In addition to this the last Milroy lectures<sup>2</sup> went into the subject of "Public Health and Housing" very fully, and there have been several instructive discussions on this subject. Quite recently a deputation of the Association of Municipal Corporations waited upon the President of the Local Government Board with the view of urging certain points—notably, perhaps, an extended period for the repayment of borrowed money—upon him. Mr. LONG lent a sympathetic ear, but it would not appear that there is any chance of legislation on the subject albeit the problem may possibly be handed over for the consideration of another Royal Commission. But it cannot, however, be said that 1901 has been barren in connexion with the housing question. The sympathy of the KING is with those whose faces are turned towards the light and the County Council will not be likely to let the matter rest seeing what they have

already accomplished. Moreover, will not the new borough councils feel that in facing this question they will be doing something to justify their new chains of office? In the meantime the problem will be materially modified by the development of the electric tramway system which will in point of distance take the workers further from their work and in point of time bring them nearer.

#### *The Control of Factories and Workshops.*

The consolidation and amendment of the Factory and Workshops Acts by the Act of 1901 and the energetic application of its provisions should conduce very materially to the health, comfort, and safety of the artisan population of this country. Although the sections bearing directly upon health form but a small portion of the Act the provisions relating to the prevention of accidents, the limitation of the hours of labour, the exclusion from work of recently delivered women, and the control of dangerous and unhealthy industries are all matters which bear upon the health of present and future generations of workers. The sanitary control of workshops has hardly been dealt with in the annual reports of medical officers of health as thoroughly as could have been wished in the past, and it is to be hoped that the new Act will act as a stimulus in this respect. The State in its turn should see that the Government factories and workshops afford an example to other employers of labour.

#### *The Metropolitan Borough Councils.*

It is as yet too early to extol or to criticise the new metropolitan borough councils, but it is certain that they are being closely watched by all those anxious for sanitary reform in the metropolis. The near future will determine whether these new administrative bodies are merely the old vestries under another name or whether they consist of men anxious to bring about a different condition of affairs in the matter of the housing of the poor, of better lighting, and the more liberal provision of sanitary conveniences, &c. Fortunately these councils have at their disposal medical officers of health who are capable of advising them and who are, moreover, free to speak their minds as to the sanitary requirements of their districts without fear of dismissal.

#### *The Public Health Legislation of 1901.*

In this particular but little has reached the statute book; indeed, but little has been attempted. The Isolation Hospitals Act and the Factory and Workshops Act are the only two measures which can lay claim to be regarded as of public health interest, and even these, seeing that they are both amending Acts, can hardly rank as of first-class importance. During the year Mr. LONG seems to have been framing a Bill to deal with the difficult question of forming a board for water-London, and there are, we take it, prospects of a consolidation of the Public Health Acts. In our next Annus Medicus we shall, we hope, be able to record more progress.

#### THE GENERAL MEDICAL COUNCIL.

The General Medical Council held its two usual sessions in the course of the year, each lasting seven days. The summer meeting, beginning on June 4th, was the seventy-first session of the Council. Two personal changes were noticeable at this meeting. Dr. NORMAN MOORE succeeded Sir DYCE DUCKWORTH as representative of the Royal College of Physicians of London and Sir JOHN WILLIAMS succeeded Mr. T. PRIDGIN TEALE who retired with the universal respect of the Council after 25 years' service as Crown Representative. Though the Council sat seven days in each of the two sessions the business transacted was not large and was similar, not to say identical, in both.

#### *The Disciplinary Work of the Council.*

Of late the Council has commenced its penal or disciplinary business on the Wednesday and has disposed of it with dispatch, while no one can accuse it of any want of

<sup>1</sup> THE LANCET, Jan. 12th (p. 124) and 19th (p. 205) and Feb. 2nd (p. 351), 1901.

<sup>2</sup> THE LANCET, March 2nd (p. 679), 9th (p. 679), and 23rd (p. 837), 1901.

consideration to accused persons. It is a happy circumstance that though numerous practitioners have been summoned to attend on charges of unprofessional conduct in only one case has the Council proceeded to order the removal of a name from the Register—that of a practitioner found guilty of committing adultery with a lady whom he had professionally attended. Three other cases were of sufficient novelty and importance to be mentioned here. Dr. HENRY WARD IRVINE, it will be remembered, had accepted the office of consulting physician to the Consultative Medical and Surgical Institution, Birmingham, at a salary, and was charged with having approved or acquiesced in the extensive advertisements issued by that institution referring to his special ability as a general consulting practitioner. The Council in December, 1900, found the charges proved. Dr. IRVINE then, in the course of the inquiry, showed that he had scarcely realised the objectionable and unseemly system to which he had unfortunately left his name and qualifications. He was given time to consider his position and soon resigned his office. Accordingly the General Medical Council at the June meeting did not proceed further with the case and it ended in Dr. IRVINE thanking the Council for its decision and for the care with which it had gone into his case. Dr. J. MARTIN THOMSON of Airdrie, Scotland, had been found by the Council in December, 1900, to have employed habitually unqualified assistants to sell poisons, so violating the Pharmacy Acts. Time was given him to consider his position. He immediately submitted himself to the judgment of the Council and engaged a qualified assistant. On his reappearance at the June session and on his satisfying the Council of his loyalty to its decision the Council resolved to desist from further proceedings. At the recent session no less than seven practitioners from the West of Scotland were charged with a similar offence—viz., keeping unqualified assistants and allowing them to sell scheduled poisons. It was urged in mitigation of their offence that they acted so before knowing the judgment of the Council in Dr. THOMSON's case. On their undertaking to discontinue the employment of unqualified assistants the Council, through its President, announced its intention not to proceed further with the matter. But it very properly resolved at a later stage of the recent session to issue a warning against such a system as occasion may arise to all practitioners. Three dentists were charged before the Council at the June meeting with advertising in various ways. They promised to desist from the practice and the Council dismissed the cases. Our notice of the penal cases would be incomplete without an allusion to the important case of Dr. ROBERT RENDALL, who was charged with "accepting, and continuing to hold, the appointment of medical officer to the Liverpool Victoria Legal Friendly Society at Great Yarmouth, a society which systematically practises canvassing for the purpose of procuring patients, and with approving and acquiescing in such canvassing." It should be stated that Dr. RENDALL was also medical officer to the National Medical Aid Company which was worked in association with the Liverpool Victoria Legal Friendly Society. The case is, in a sense, still *sub judice*, but the Council found the allegations proved and adjourned the final consideration of the case to the next ordinary meeting of the Council. The case excited much interest, partly on account of the eminent counsel employed and partly because it tests the power of the Council to deal earnestly and effectively with a system that is injurious to the profession and to the poor alike. The judgment of the Council in no way turned on the fees charged to members entering the National Medical Aid Company, but had reference solely to the touting and advertising system by which the patients were secured.

#### *Recognition of Foreign and Colonial Diplomas.*

There is little in the way of actual work done to put to

the credit of the Council in either session. The proposal to extend the second part of the Act of 1886 to the Kingdom of Italy and the University of Malta was discussed in the Council at both its sessions. Acting under the advice and on the report of its Education Committee in the recent session it reported in favour of the extension in both cases—or rather it resolved to report that in both cases the requirements of the universities for their respective degrees were such as to provide a sufficient guarantee of the requisite knowledge and skill for the efficient practice of medicine, surgery, and midwifery. It will be well for the Council to take an opportunity of representing to the Government the want of power and of means on the Council's part to inspect foreign and colonial examinations as it does the home examinations. But it wisely did not allow this consideration to interfere with its duty to make such report as it could with regard to the curricula in Italy and Malta respectively.

#### *The Raising of Preliminary Education.*

The members of the Education Committee were able to complete their report on the steps taken by them to give effect to the recommendations and suggestions for the improvement of preliminary examinations. They have virtually come to a satisfactory understanding with the College of Preceptors, the Royal College of Physicians of Ireland, the Royal College of Surgeons in Ireland, and the Educational Institute of Scotland. These bodies have further agreed to forward their marked papers to the committee from time to time. The Council expressed great satisfaction with the work done by its committee and allowed a further grant for the purpose of inspecting certain of the recognised preliminary examinations in general education during the year 1902.

#### *Slow and Expensive Working of the Council and the Dispute with the English Royal Colleges.*

Other business of the Council had to stand over. For two or three sessions it has been trying to formulate rules to prevent personation for purposes of false registration. The subject again occupied part of two days of the recent session and was then sent back to the Personation Committee. At the June meeting a special committee was appointed to report in November on amendments of the Medical Acts for adjusting the relations between the General Medical Council and the Branch Councils and for placing the financial position of the Council on a satisfactory basis. But no such report was made or attempted, in spite of the fact that the English Branch Council only avoided the sale of consols at a great loss for payment of its excessive expenditure by borrowing £600 from the Dental Fund. Such constant adjournment of important business to the next session threatens to bring both embarrassment and discredit to the Council. The chief explanation is the state of discord to which the Council has been brought by the dispute between itself and the Royal College of Physicians of London and the Royal College of Surgeons of England on the subject of science teaching and the institutions where it shall be taken. Three separate discussions on this subject ended in the appointment of a committee to frame a report which is to be discussed at a special meeting of the Council in February. Of this committee Dr. D. C. McVAIL is the chairman. The special meeting will involve a further expense of £500 or £600. Perhaps the best resolution passed by the Council at its late meeting was that re-appointing Sir WILLIAM TURNER as President for another term of five years. Sir WILLIAM TURNER is a model chairman, whether we regard his business faculty, his knowledge of medical education, or his deep personal interest in those great medico-political questions which so much affect the reputation and efficiency of the profession.

*The Election of Direct Representatives.*

Since the close of the November session the election of Direct Representatives has taken place. A very large proportion of the registered practitioners abstained from voting. The result is the election of Mr. GEORGE JACKSON of Plymouth and the re-election of Mr. GEORGE BROWN of London for England, and the re-election of Dr. W. BRUCE for Scotland. Dr. J. G. GLOVER, being advised by his medical friends to take no active part in the election, thought it right to retire from the contest—a course which has been much regretted both inside and outside the General Medical Council of which he was a member for 15 years.

## THE BRITISH MEDICAL ASSOCIATION.

The sixty-ninth annual meeting of the British Medical Association was opened at Cheltenham on July 30th. The President was Dr. GEORGE BAGOT FERGUSON, senior surgeon to the Cheltenham Hospital. The occasion was the second on which the Association had visited Cheltenham, the last visit having been paid in the year of the accession of Queen VICTORIA. Dr. FERGUSON took as the subject of his Presidential Address, "Scientific Research: the Indispensable Basis of all Medical and Material Progress." Dr. FERGUSON may be congratulated upon his skill in making a *résumé* of medical progress, not, to use a term adopted from the kitchen, a mere *réchauffé*, but an interesting and scholarly descriptive account. The Address in Medicine, entitled "Friends in Council," was delivered by Dr. JAMES F. GOODHART and we need do no more than say that in it he was at his very best. The Address in Surgery was delivered by Sir WILLIAM THOMSON who took for his subject a theme which at the present time comes home to all of us—namely, "Some Surgical Lessons from the Campaign in South Africa." No address was delivered in obstetrics. With regard to the general meetings, by far the most important business transacted thereat was the consideration of the report of the Constitution Committee, which was received with one or two amendments. In the proceedings of sections many interesting papers were read. Among the foreign guests present were Dr. SABOURAUD of Paris, Dr. G. DOCK of Michigan, and Professor ONODI of Budapest. There were also present at the meeting various delegates from the colonial branches of the Association.

## VARIOUS HOSPITAL FUNDS.

*The Metropolitan Hospital Sunday Fund.*

The history of the Metropolitan Hospital Sunday Fund year by year might be summed up in one word—"success," for in spite of gloomy forebodings before the annual collections the promoters of the Fund have generally had cause to congratulate themselves on the result of their labours. The amount collected during the year 1901 was £54,731 19s. 3d., £2738 4s. 9d. in excess of the amount collected in 1900, and, with the exception of the year 1895, when the Fund exceeded £60,000—this amount is the highest yet recorded. The total sums collected by congregations of various denominations amounted to £36,388 6s. 4d. Prebendary RIDGEWAY of Christ Church, Lancaster-gate, collected £1317; Canon FLEMING of St. Michael's, Chester-square, £1233; and Prebendary STORRS of St. Peter's, Eaton-square, £652. There was an increase of £532 in the collections from contributing congregations which numbered 16 more than last year. Mr. GEORGE HERRING for the third time gave a donation of £10,000; Sir FREDERICK L. COOK, Bart., M.P., gave a special donation of £4000; Sir SAVILE CROSSLEY, Bart., again generously contributed £500 (for the tenth time); "A. G. P." gave £200; and "Delta" contributed his twenty-third donation of £200. The number of hospitals that participated in the division of the funds was 144, and the number of dispensaries 53.

*The Hospital Saturday Fund.*

The Hospital Saturday Fund has made steady progress during the year, the income being £20,300, as compared with £20,014 in 1900. It is interesting to note the progress that the Fund has made since the abolition of the street collection in 1897. In that year £20,138 were collected, including £3330 from street boxes. It will be seen that the Fund has more than recovered the loss incurred by the abolition of the street collection and has distinctly increased in public favour. The main income of the Fund is derived from the penny-a-week collections in the workshops and places of business in London. This is steadily maintained notwithstanding the many other claims which are made upon the small resources of the workers. A special department has been created for the supply of surgical instruments upon payment by the patients of 50 per cent. of the estimated cost. Over 3000 instruments are annually provided by this department under the supervision of a special committee assisted by competent surgeons and fitters. Towards the cost of these appliances the patients contribute over £1400. Special arrangements are also made for sending men, women, and children to convalescent homes when recommended for such benefit by a medical man. Over 1200 patients were sent away during 1901, many on the part-pay system, nearly £400 being paid by the patients or their friends towards the cost of their maintenance. Another special department of the Fund is the ambulance department, through which men and women are trained to render first aid in cases of accidents in the workshops or in the streets, mostly in the workshops; and in cases where the employés of any firm subscribe £5 per annum to the Fund and employ a man or woman holding a First Aid Certificate of the St. John Ambulance Association they are supplied on loan with completely fitted ambulance boxes. The awards for 1901 amounted to £18,700, as against £17,690 in 1900.

*Prince of Wales's Hospital Fund.*

This is the last year in which the Fund will bear the above title, for His Majesty has decided that on Jan. 1st next the Fund shall be known by the name of "King Edward's Hospital Fund for London." Since its inception in the Diamond Jubilee year of her late Majesty Queen VICTORIA the Fund has made steady progress. Excluding the first collection in 1897 the annual totals have been as follows: In 1898, £39,272; in 1899, £48,536; and in 1900, £51,549, the last-named sum including £6000 collected by the League of Mercy. Of the sum collected in 1900 £50,000 were awarded to hospitals and convalescent homes. The expenditure for 1900 was £1960. The complete figures for the year 1901 are not yet to hand, but the receipts up to Dec. 16th amounted to about £53,000. This sum does not include various coronation gifts. £50,000 will be distributed among hospitals and £1000 among convalescent homes. The League of Mercy has contributed £7000, an increase of £1000 over last year's collection. It will be remembered that the Royal founder of the Fund explained its object as being "to attach the sentiment of gratitude for the blessings which the country has enjoyed during the last 60 years to a scheme of permanent beneficence," and we re-echo the wish of the General Council of the Fund in hoping that year by year the Fund will continue surely and steadily to grow and will become a permanent memorial of the blessings of the long and beneficent reign of our late Sovereign, and one worthy of the great progress made by the nation in the years during which she reigned over it.

The year 1902 being the Coronation year of the KING even greater efforts than have been made in the past will, we trust, be made to increase the total receipts of all the hospital funds.

To release the hospitals from debt is a wish very near to the heart of the KING, and there is nothing which would

give His Majesty greater gratification than to know that in the year in which he was crowned his wish had been fulfilled.

#### SANITATION.

The question of registering and controlling itinerant manufacturers of penny ices has this year been actively taken in hand by the London County Council, thus following the example of the towns of Liverpool and Brighton. This is a subject which we brought prominently to notice so far back as in the year 1878, and yet even to-day the Italians still continue in making ices to expose the milk which they employ to very filthy surroundings. There is no reason why this business should not be controlled in the same manner as are milkshops and dairies. As we pointed out during the course of the year, these Italians are a thrifty, sober people, and there is no cause to apprehend that they would resist regulations that are as much to their own benefit as they are to that of the general public.

We likewise protested against the omission of laundries from the new Factory Bill. Our revelations with regard to the contamination of linen, also published many years ago, had led to the formation of what professed to be model steam and sanitary laundries. But over and above such efforts of private enterprise it is necessary that strict measures should be taken to prevent any possibility of clean linen being contaminated by close proximity in laundry establishments to soiled linen that may come from persons suffering from infectious diseases. With the recrudescence of small-pox and with travellers arriving in this country from places where plague prevails those who handle what is worn nearest to the skin should be carefully watched. Though the sanitary authorities have, with praiseworthy alertness and skill, so far succeeded in stamping out the danger of infection arising from the few cases of plague which have been imported into this country, no one can have read our description of the slums of Glasgow and feel altogether safe. What is particularly discouraging in Glasgow and many other places is the fact that much of the squalor, overcrowding, and filth that prevail is not due to poverty but to the thriftless, drunken habits of men and women who are in receipt of good wages. In regard to small-pox, however, and though it is now an old story, we recently recalled the fact when dealing with the sanitary condition of the town of Gloucester that the prevalence of this disease depended on the neglect of vaccination rather than on sanitation. The great epidemic of small-pox at Gloucester affected a quarter of the town where the density of population only amounted to 31.41 persons per acre. The older part of the town, where the poorer section of the population crowded together to the extent of 64.3 persons per acre and dwelt in ancient houses that were not so well drained or so well ventilated, practically escaped from the effects of the epidemic. This is a fact which, in face of the present prevalence of small-pox in the metropolis, is worth bearing in mind. In describing the sanitary condition of Edinburgh we come to quite the opposite conclusion in regard to the fatality due to measles. Here the average for the last three years showed that out of 100 cases of measles there had been 4.23 deaths in the Old Town district, where the greatest poverty and overcrowding existed. In the two other and more favoured districts the percentage of mortality in cases of measles was only 1.96 and 0.40. In the same articles the stringent laws enacted formerly to cope with plague and other epidemics were described, as also was the isolation hospital which is now in course of erection, and which will deal with these diseases in the future. We likewise gave an account of the Victoria Hospital for the Treatment of Consumption where, in a beautiful park in the outskirts of Edinburgh, the patients are kept constantly out of doors. In spite of the rigorous climate excellent results have been obtained.

From abroad we received a detailed account of the slow

progress made in Paris in the work of connecting the houses with the now completed system of drainage. What has been done, in spite of the organised resistance of the house proprietors, has materially contributed to reduce the prevalence of typhoid fever. But the most useful example given comes from the energetic action of M. MILLERAND, Minister of Commerce and the Post and Telegraphs. Drastic measures have been taken better to protect the health of the 70,000 postal servants in the employ of the French Government. The prevalence of tuberculosis among letter-sorters has led to the adoption of severe measures to prevent spitting on the floors of the post-offices and for the enforcement of greater cleanliness and the abolition of dry sweeping. Now only moistened dusters are employed. At the same time the position of the postal medical officers was much improved and the staff was increased. We then compared at length the position of the British and the French postal medical officers. The latter are paid in strict accordance with the amount of work that they do, receiving a regular salary for attending at the surgery during certain hours in the week and a separate fee for every visit paid to a patient in his own home. Then there are besides consulting physicians and surgeons for the more severe operations. In England there are no such complications. The club system has been adopted; but the postal medical officer receives 8s. 6d. per head for every employé on his list, instead of 4s. 4d., which is the usual price paid by the clubs and medical aid associations. But there are other indirect advantages that tend to improve the position of British postal medical officers. They have a large association with some 600 members and they have petitioned for the adoption in England of some of the reforms recently introduced in France.

#### THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

Sir WILLIAM SELBY CHURCH, Bart., was for the third time elected President, the practically unanimous vote of the Fellows testifying to their approval of the manner in which he had fulfilled the onerous position of head of the College.

At the meeting of the Comitia held on Jan. 31st the President proposed from the chair the following motion:—

"That this College humbly approach His Majesty the KING and express profound sorrow at the loss which His Majesty and the Royal Family have sustained, and at the same time assure him of our loyalty and devotion to his throne and person."

This having been adopted by the College, on March 20th an address was drawn up and presented by a deputation and a gracious reply was received.

Certain by-laws referring to the third or final examination were altered to render them conformable to the regulations of the Conjoint Board.

The most important discussion of the year took place in respect to the registration of medical students. The General Medical Council requires that no medical student shall be registered until he has passed a preliminary examination as required by the General Medical Council and has produced evidence that he has commenced his medical studies at a university or school of medicine, or at a scientific institution recognised by one of the licensing bodies and approved by the Council. It was to the last phrase that the Royal College of Physicians (and the Royal College of Surgeons) objected. After a prolonged discussion the College maintained their right to select the teaching institutions where elementary scientific studies might be pursued.

As a result of this discussion a motion was adopted to alter certain by-laws which will have the effect that in future proofs of registration by the General Medical Council will no longer be required from candidates for diplomas granted by the Conjoint Board.

Dr. NORMAN MOORE was elected as the representative of

the College on the General Medical Council for a term of five years from May 14th, 1901.

A fear had been expressed that the laboratories at the Examination Hall would have to be closed on account of lack of funds. It was, however, resolved that, provided the expenses were strictly limited to £1300, the College of Physicians would be prepared to bear their share as heretofore in carrying on the work of the laboratories.

A letter was received from Mrs. T. FITZPATRICK offering the sum of £2000 to found a lectureship at the College in the history of medicine in memory of her late husband, a Member of the College. The offer was gratefully accepted.

The Baly Medal was awarded to Dr. F. W. PAVY for his researches on the Physiology of the Carbohydrates: their Application as Foods and Relation to Diabetes. The following lectures were delivered during the year: the Milroy Lectures, by Dr. J. F. J. SYKES, on Public Health and Housing: the Influence of the Dwelling upon Health in Relation to the Changing Style of Habitation; the Lumleian Lectures, by Dr. F. J. PAYNE, on Cancer, especially of the Internal Organs; the Croonian Lectures, by Dr. W. D. HALLIBURTON, on the Chemical Side of Nervous Activity; and the Bradshaw Lecture, by Dr. JUDSON S. BURY, on Prognosis in Relation to Disease of the Nervous System. The Goulstonian Lectures were postponed owing to the illness of Dr. H. HEAD, but were subsequently delivered, the subject being Certain Mental Changes that accompany Visceral Disease. Dr. NORMAN MOORE was the Harveian orator for the year.

#### THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

The thirteenth election of members of Council under the new regulations to fill the vacancies caused by the retirement in rotation of Mr. N. C. MACNAMARA, Mr. A. W. MAYO ROBSON, and Mr. W. WATSON CHEYNE was held in July. Mr. MACNAMARA did not apply for re-election, and Mr. MAYO ROBSON, Mr. WATSON CHEYNE, and Mr. CLEMENT LUCAS were elected. There were eight candidates, and 768 Fellows voted, but of these only 18 voted personally.

Mr. H. G. HOWSE was elected President and Mr. T. R. JESSOP and Mr. F. HOWARD MARSH were appointed Vice-Presidents.

The Hunterian Oration was delivered by Mr. N. C. MACNAMARA who took as his subject Craniology. The Hunterian dinner was not held in consequence of the death of Queen VICTORIA.

Mr. T. R. JESSOP delivered the Bradshaw Lecture on Personal Experiences in the Surgical Treatment of Certain Diseases.

The Triennial prize was not awarded, and for the next prize the subject chosen was "The Pathological Conditions Arising from Imperfect Closure of the Visceral Clefts."

The Jacksonian prize was awarded to Mr. W. MCADAM ECCLES for his essay on the Pathology, Diagnosis, and Treatment of the Diseases caused by, and connected with, Imperfect Descent of the Testicle. The subject for the next Jacksonian prize is Fracture of the Skull: its Consequences, Immediate and Remote, including Pathology and Treatment.

The Walker prize was not awarded and rules were framed for the Cartwright prize, which is to be awarded for some subject connected with dental surgery. Two members of 20 years' standing were elected to the Fellowship: Mr. J. PRIESTLEY SMITH of Birmingham and Major RONALD ROSS, late I.M.S., of Liverpool. Mr. THOMAS BRYANT was reappointed Representative of the College on the General Medical Council for a further period of five years. The annual meeting of Fellows was called for July 4th, but the quorum of 30 was not obtained and therefore once more no meeting was held. At the annual meeting of Fellows and Members in November 54 were present and a motion was

carried asking the Council to suggest some method by which the Members might be represented on the Council. Motions were also passed in favour of changes in the Medical Acts and of the election of the representative of the College on the General Medical Council by the Fellows and by Members of 10 years' standing. It was also resolved that the Council was unwise in opposing the action of the General Medical Council in the matter of institutions for the teaching of elementary science. The gross income of the College for the year was £26,104 and the expenditure was £23,989. The secretary of the College, Mr. EDWARD TRIMMER, M.A., resigned early in the year after 42 years' service and was presented with an address by the Council. He was granted a pension in consideration of his long service. The assistant secretary, Mr. SIBERT COWELL, was appointed secretary. The names of all members of the College who were admitted before 1843 have been removed from the Register except in cases where there is evidence of their being still alive. The College has sustained a serious loss in the death of Sir WILLIAM MAC CORMAC, Bart., K.C.B., K.C.V.O., who held the office of President of the College for five years.

#### THE BENEVOLENT AGENCIES OF THE PROFESSION.

##### *Royal Medical Benevolent College.*

This institution continues to carry on its useful work. From the funds of the charity a first-class education with clothing and maintenance is given to 50 foundation scholars, the orphans or necessitous sons of medical men, and pensions of £30 a year are given to 50 aged and distressed medical men or to the widows of those deceased. There are nine "Pugh" pensions of £30; three "Morgan" annuities of £20, for the aged daughters of medical men; and two "Da Silva" pensions of £20 for aged pensioners (in addition to their ordinary pensions); and under the will of the late Mr. FRANCE, who was a warm supporter of the college from its foundation, further pensions will soon be available for medical men, the choice of these being left in the hands of the Council. There are in connexion with the institution 11 presentations to the schools of St. Anne's Society for the daughters of medical men. As may be understood, in the case of an institution dating back about 50 years numerous old friends are lost by death year after year, so that fresh supporters are urgently required in order to maintain the good work. Annual subscriptions of one guinea give voting power, but the council emphasises the fact that small subscriptions are welcome. We are constantly urging the claims of this institution upon our readers, and may once more express the hope that those practitioners who do not now subscribe to the institution will become regular contributors, if only of 5s. a year. The secretary is Mr. J. B. LAMB, 37, Soho-square, W.

##### *British Medical Benevolent Fund.*

In the grant department the income of the British Medical Benevolent Fund has not been sufficient to cover the outlay, and additional subscriptions and donations are urgently needed to meet the constant demands upon this department. Had it not been for a balance brought forward from 1900 several most deserving cases would have been passed over. The income for the year from subscriptions and donations is £1400—a falling off of nearly £300 as compared with 1900—whilst £1614 have been voted for the relief of 155 applicants. The annuity account shows an income from investments of £2402, £2288 of which have been paid to 114 annuitants. Two legacies were received during the year—viz., £21 left by the late Mrs. MACKENZIE of Bury, and £100 by the late Sir EDWIN SAUNDERS.

##### *Society for Relief of Widows and Orphans of Medical Men.*

The grants given by this fund in 1900 amounted to £3034 10s. and the expenses to £244. The receipts totalled

£3388 8s. 6d. 47 widows and 14 orphans were assisted. The number of new members elected amounted to seven, while the society lost 17 members by death or resignation. The funded property is now £98,350. The accounts for 1901 have not yet been made up.

#### THE LANCET Relief Fund.

THE LANCET Relief Fund, which was established in 1889 by the proprietors of THE LANCET for the purpose of affording immediate pecuniary assistance to medical men or their widows and orphans in cases of distress and emergency, by grants of money on loan free of interest or by gifts, has assisted some 37 persons during the past year, involving an expenditure of £383 10s.—the largest sum allotted in any one year since the inauguration of the Fund. As the accounts are not made up till the end of the year there is a probability that these figures may fall short of the actual totals.

#### ANALYTICAL COMMISSIONS OF THE LANCET.

Several investigations involving experimental work in THE LANCET Laboratory were undertaken during the year. First in importance was that which related to the scope of arsenical contamination traceable to impure sulphuric acid. It was shown that the use of sulphuric acid was associated with the production of many articles of food and this fact prompted an experimental inquiry as to the presence of arsenic in many commonly occurring substances. Amongst those examined were tobacco, including cigars and cigarettes, jams, sweetmeats, lemonade, liqueurs, boric acid, oleic acid, soap, blacking, glycerine, effervescent salts, Glauber's salt, alum, fertilisers, lemon juice, lime juice, and grape juice. The results on the whole were reassuring. Arsenic was found in blacking, soap, artificial Carlsbad salts, Glauber's salt, and in artificial fertilisers. No arsenic could be traced in the articles of food examined. Nevertheless, it was pointed out that the lesson of the beer-poisoning epidemic should leave not the shadow of a chance of such a disaster occurring again. The danger involved by the use of sulphuric acid in the manufacture of all compounds intended for human consumption can be obviously avoided by the use of strictly pure sulphuric acid, and some rigid precautions are necessary which shall ensure the supply of arsenic-free sulphuric acid for these special purposes. We have no doubt that the Royal Commission on arsenic will make a strong recommendation to that effect.

In THE LANCET of March 2nd, 1901, we published an analysis of an "anti-rheumatic ring" in which we showed that it could not possibly possess any anti-rheumatic properties whatever. It consisted of metallic iron, and the fact that it formed a slight rust gradually on the moist finger persuaded some people that it effected the elimination of uric acid from the system. In THE LANCET of March 16th we raised an important point in regard to the amount of alcohol which may be normally developed in a natural wine. The question arose on the occasion of some South Australian wines being examined in THE LANCET Laboratory which showed a strength of as much as 29.0 per cent. of proof spirit, or even higher. It is generally laid down that the amount of alcohol produced in a normal fermentation does not usually exceed 12 per cent. by weight, which is equivalent to about 26 per cent. of proof spirit. According to the report of a special commission appointed by the Colonial Government to inquire into the alcoholic strength of South Australian wines the conclusion was that it was possible for a natural wine to contain as much as 38.5 per cent. of proof spirit or even a higher proportion. If this be so a difficulty is presented in raising a presumption as to when a wine is fortified.

In THE LANCET of March 23rd we drew attention to the fact that much of the bottled beer on the market is super-carbonated, not with its own gas, the gas of fermentation, but with artificial gas forced into the liquid in a similar way to that by which soda-water is made.

There is no doubt that beer so treated is dietetically inferior to beer charged with its own natural gas. Moreover, the practice is to be discouraged, as not improbably it may be used to pass off unsound and vapid beer as wholesome. In THE LANCET of April 20th we recorded the fact that sweets had come into our possession which had been liberally sprinkled with glass splinters in order to make them glitter. Our analysis showed the existence of sharp flakes of glass. The sweets were sent to us by a correspondent who thought possibly that they might account for the production of severe abdominal pain in two little children who were under his care. In spite of the fact that our analysis enabled us to say most positively that these glittering particles were glass, members of the confectionery trade were incredulous and were good enough to say that they did not believe our assertion. To do them justice we may add that we have since examined a great number of sweets, but in no other instance have we found glass to be used. We therefore regard the instance as an accident in the course of manufacture, but it might have been a very dangerous one. In THE LANCET of April 27th appeared an analysis of the deposit of the thermal springs at Bath. The deposit was taken from a pipe which had not been opened for 20 years, and since thousands of gallons had passed through the pipe it was thought to be possible that some of the rarer constituents might be found in tangible quantity. The analysis, however, as made in THE LANCET Laboratory showed only the presence of the salts of the alkaline earths, calcium sulphate, calcium carbonate, magnesium carbonate, and iron. There were, however, distinct traces of copper which have been reported to be found in the water in previous analyses by other observers. After all, the rare constituents of the Bath waters are probably soluble and such as would not occur in a deposit. In previous analyses of the water we found distinct evidences of the presence of lithium, strontium, and bromine. In THE LANCET of June 22nd we recorded the results of analyses of several coloured papers used by the London newspapers. Although we found Prussian blue and aniline dyes in the green and pink coloured evening papers there was no evidence of arsenic or other injurious ingredient. As old newspapers are often used as wrappers for food the results were of interest, but, as was pointed out, there can be little doubt that newspapers might easily become tainted with pathogenic germs, and on that account it is desirable that care should be taken to wrap food, not in newspapers which are exposed to all sorts of infective risks, but in paper specially prepared for the purpose.

In a special article in THE LANCET of July 13th a full description was given of an improved form of the Finsen apparatus for the treatment of lupus by light rays.

An analysis was made in THE LANCET Laboratory of an artificial flower and the results were recorded in our issue of July 20th. The flower was supposed to be a carnation and it possessed a scent similar to that of the carnation. A laboratory examination, however, showed that there was not the vestige of a carnation about it. The flower consisted of slices of turnip neatly cut and dyed with acid magenta, the stems and leaves were of twisted cloth dyed a dark green with chromium, the bloom was a very fine starch powder delicately dusted over the stems and leaves, and the support to the whole clever fabric was a concealed iron wire. Lastly, a synthetic amber-coloured oil completed the deception in giving a perfume wonderfully imitative of the genuine carnation. It is satisfactory to add that in spite of this clever deception there was no evidence of the presence of injurious colourings or other substances.

Our Analytical Commissioners took occasion during the hot summer months to secure samples for analysis of ice in

London representing the ice commonly supplied for cooling drinks and for other purposes. It was found that most of the ice supplied in London shops was Norwegian ice and that, moreover, it was of excellent quality, pure and clean. The water which was yielded on melting contained less than a grain per gallon of dissolved mineral matter, no nitrogen in organic or mineral shape, and but a trace of chlorides. This result confirmed the previous results obtained by THE LANCET Special Analytical Sanitary Commission on the Character and Quality of the Ice-supply of London in 1893. One curious fact came to light during the experiments and that was that when pure ice such as Norwegian ice is allowed to melt in a leaden vessel the resulting water will be found to be contaminated with a very appreciable amount of the lead. On another occasion we pointed out the undesirability of exposing food for sale in the streets. In one particular instance a piece of salmon bought at a fishmonger's shop in a street at a time when new "pickled" wooden blocks were being laid down evinced a strong odour and taste of naphthalene, showing how easily articles of food so exposed can become contaminated.

Quite recently some laboratory experiments have been made with a new gas stove known as the Clamond Gas Radiator, the inquiry being more particularly directed to the points of view of heating efficiency and health. We may briefly recapitulate the results. It was shown that this new gas-heating appliance was remarkable in producing radiant heat presenting the appearance of a bright, cheery fire. The consumption of gas in regard to the heating effect upon the air of a room was remarkably small, while no vitiating effect upon the air could be traced. These excellent results may be attributed to the fact that the radiator is constructed with the Kern burner, a burner which produces a very intense atmospheric flame the result of the combustion of five and a half volumes of air with one volume of gas, the exact ratio requisite for complete combustion. It was therefore regarded as a distinct advance on all other gas-heating appliances, being economical, efficient, and healthy. For its efficient working the stove requires, however, a steady gas-supply and constant and sufficient pressure. A number of practical experiments were made, as will be seen from the report which appeared in THE LANCET of Nov. 30th, which we venture to think justified the above conclusions.

The number of specimens of food, drugs, and other articles examined in THE LANCET Laboratory and reported on in our columns was 107, and the number of individual analytical investigations thereby involved was 323. In connexion with special work, some 142 analytical observations were made, bringing up the total to 465.

#### THE HOUSING OF THE POOR.

The fact, possibly, that so many volunteers and recruits have had to be rejected because they did not come up to the military physical standard may, in a measure, account for the increased interest manifested this year in regard to the housing problem. Undoubtedly overcrowded dwellings, especially in populous and large towns, must result in physical degeneration. In the earlier months of the year we gave in a series of articles an account of what both the Metropolitan Board of Works and its successor the London County Council have done and what the latter body is now doing to provide healthier and cheaper dwellings for the working classes. It was no easy matter to give a condensed account of so many and such complicated schemes together with an analysis of the law on the subject. But this work was all the more necessary in consequence of the recent creation of district and town councils and the extensive powers given to them, including the right to purchase land for housing purposes outside of their own boundaries. The application of Part III. of the Act, now much more

general, gives good promise, because it enables local authorities to purchase and to keep land, so that in time they may hope to recoup the outlay which they incur out of the rents that they will receive from their tenants. But, nevertheless, we showed that the law was still far too complicated and its application too costly. Therefore, though a great deal has been achieved and much more is promised, still, so far as London is concerned, the realisation of all the outstanding projects will at best only serve to prevent the present grievances from becoming worse. The number of people to be housed by the County Council only keeps pace with the increase of population. Therefore, unless a good deal more is done than is at present contemplated, matters will remain much as they are, unless, of course, some unforeseen cause were to check the flow of new residents to the metropolis.

#### The Glasgow Congress.

During the Glasgow International Exhibition many congresses met in that city, and we described the lengthy and varied discussions which were then held on this grave problem. The International Congress of Engineers dealt with it at length, and there was an important debate on the subject in one of the sections of the British Association which likewise met at Glasgow. Finally, the Glasgow Town Council conceived the excellent idea of convoking a conference of municipal representatives from all parts of the kingdom to relate what they had done in their respective towns and to debate on the best means of proceeding. A reference to the lengthy descriptions we gave of these discussions<sup>1</sup> will show that throughout there was a dual current of opinion. There were those who were concerned with the deserving poor and there were others who were far more anxious about the undeserving poor. From the sanitary point of view the latter certainly create the most urgent problem. Much has already been done for the deserving poor, and the great fault of all the schemes that have been carried out is that they provide homes for a respectable class of tenants who do not occasion any great danger to the public health. The thriftless and the drunkards, the very filthy and degraded sections of the population still herd together in unspeakable hovels and rookeries, or degrade any better class of property to which they may gain access. To meet this danger a dual system of coercion was proposed. First, the municipalities, it was suggested, should build shelters at the cheapest possible rates, where the rent charged ought not to be more than 1s. per week per room. To these anyone, however disreputable, was to be admitted; but, once within, such tenants were to be severely watched and coerced into living fairly cleanly and healthy lives. Second, once this accommodation had been provided then another resort to coercion was to be made, and this time against all farmers-out of tenements and lodgings who allowed overcrowding and filthy habits on their premises. Many other and very important questions were discussed, but the suggestion just mentioned was the most original that was made during these conferences and congresses.

#### THE ORGANISATION OF THE PROFESSION.

In regard to the work of organisation undoubtedly the meeting of the British Medical Association at Cheltenham was the greatest event of the year. Here a new constitution for the Association was adopted which if carried out in letter and spirit would convert this great Association into a fighting union capable of taking up all the ethical and economic questions and grievances which have troubled the profession for so long. But this proposed change is so sudden, so radical, and so sweeping that it is impossible to avoid the expression of some doubts. The special descriptions which we published of the general meetings where all these mighty changes were adopted cannot be taken as very encouraging.

<sup>1</sup> THE LANCET, Oct. 5th (p. 943) and 19th, 1901 (p. 1081).

The majority of the members of the British Medical Association were lured away by the attractions of numerous garden-parties and only a zealous few remained to inaugurate the most potential alterations. The answer, of course, to these criticisms is that the lukewarm members of the Association who at Cheltenham neglected these business matters were not delegates. It therefore remains to be seen whether on the next occasion a sufficient number of earnest delegates will be elected to accomplish useful work. In the meanwhile we repeat now what we said at the time—namely, that the independent local unions must continue the task which they have taken up and are accomplishing with a considerable measure of success. During the year we have continued to describe the action and history of these organisations. We commenced with the medical unions organised in the counties of Durham and Northumberland, where now a good half of the medical practitioners are associated together so as to defend their economical interests and to create a higher school of ~~•~~unics among the members of the profession. In these counties the chief struggle has been with the medical aid organisations formed among the mining population. For the most part the miners only paid 6*d.* a fortnight for medical aid, and this was doubtless sufficient when the system was first started, some 50 years ago, for in those days the wages earned were much less than they are now. On the other hand, the cost of medical education was not so heavy and a great deal of the work was done by unqualified assistants. The present and altered conditions could, it was felt, only be met by raising the fortnightly subscription from 6*d.* to 9*d.* In many districts this increase has been obtained through the united action of the colliery surgeons and the strength of their unions. But in the towns, as for example Newcastle, Gateshead, South and North Shields, and Sunderland, the grievance in regard to friendly societies, clubs, and insurance companies exists as in the other principal towns of the kingdom. This phase of the question is not neglected, though as yet less has been done for the town practitioners than for the colliery surgeons in these two counties. The movement, however, is still only in its infancy and no complaint can be made as to loss of time. Premature action only courts disaster. It is strongly felt, especially in Northumberland, that every local practitioner must be induced to sign an agreement promising his support before a demand is made. This necessitates an immense amount of negotiation, correspondence, and many personal interviews. The practitioners of Northumberland and Durham are fortunate in having found presidents and committee-men to manage their unions who do not shrink from undertaking this arduous task and who readily incur all the loss of time and the trouble which it entails.

In the latter part of the year we described the formation, history, and action of the Birmingham and District Medical Practitioners' Union, which has now been in existence just two years. It was brought into being by the attempt to create a Consultative Institute at Birmingham and has now become a vigorous body. The consultants as well as the general practitioners came into line to prevent the formation of the proposed institute, and this first effort has proved successful; the institute has ceased to exist. Now the Birmingham practitioners are collecting data and statistics so as to attack other abuses, and in the meanwhile they are standing shoulder-to-shoulder with their fellow practitioners of Coventry who are struggling against the abuses of the Provident Dispensary in that neighbouring town. Taken altogether there has been steady progress all along the line, though an enormous amount of work still remains to be done.

#### HONOURS TO MEDICAL MEN.

The opening year of a new century has been by no means barren of honours for the medical profession, but a gloom is cast over our otherwise pleasing task of recording those

honours by reason of the sudden death in the <sup>last</sup> month of the year of Sir WILLIAM MAC CORMAC, Bart., in whose path more than in that of any other man during the year 1901 honours were strewn with gratifying profusion both to him and to the profession to which he belonged. In addition to the honours which we enumerate below the freedom of more than one of the City companies was bestowed upon him, while America honoured him by electing him a Foreign Associate Fellow of the College of Physicians of Philadelphia, the oldest medical body in America, founded as it was by BENJAMIN RUSH and other distinguished men in 1787, and H.M. the KING of ITALY conferred upon him the degree of Grand Officer of the Order of the Crown of that country.

By far the greater portion of the honours and distinctions which have fallen to our profession have been in connexion with service in South Africa and we are proud to know that three more medical heroes have been added to the roll of the Victoria Cross. Their names and the records of the gallant deeds for which they earned the distinction for valour are as follows:—

Lieutenant E. T. INKSON, R.A.M.C., on Feb. 24th, 1900, carried Second-Lieutenant DEVENISH (who was severely wounded and unable to walk) for three or four hundred yards under a very heavy fire to a place of safety. The ground over which Lieutenant INKSON had to move was much exposed, there being no cover available.

Lieutenant W. H. S. NICKERSON, R.A.M.C., attached to Mounted Infantry, at Wakkerstroom, on the evening of April 20th, 1900, during the advance of the infantry to support the mounted troops, went, in the most gallant manner, under a heavy rifle and shell fire, to attend a wounded man, dressed his wounds, and remained with him till he had him conveyed to a place of safety.

Lieutenant H. E. M. DOUGLAS, R.A.M.C., on Dec. 11th, 1899, during the action at Magersfontein, showed great gallantry and devotion under a very severe fire in advancing in the open and attending to Captain GORDON, Gordon Highlanders, who was wounded, and also attending to Major ROBINSON and other wounded men under a fearful fire. Many similar acts of devotion and gallantry were performed by Lieutenant DOUGLAS on the same day.

These officers have now been promoted to the rank of Captain.

The first Gazette in recognition of the services of officers during the operations in South Africa relating to services up to Nov. 29th, 1900, the day on which Field-Marshal Lord ROBERTS handed over the command, was issued in April. In the Royal Navy it contained the name of Staff Surgeon ERNEST COURTNEY LOMAS, R.N., who was made a Companion of the Distinguished Service Order. In the Army the following Companions of the Military Division of the Most Honourable Order of the Bath were created:—Colonel WILLIAM FLACK STEVENSON, R.A.M.C., Professor of Surgery at the Army Medical School, Netley, principal medical officer on the line of communication in South Africa; Colonel (local Surgeon-General) JAMES FRANCIS SUPPLE, R.A.M.C.; Lieutenant-Colonel (local Colonel) WILLIAM DONOVAN, R.A.M.C., principal medical officer, Cavalry Division; Lieutenant-Colonel (local Colonel) OSWALD GILLESPIE WOOD, R.A.M.C.; Lieutenant-Colonel (local Colonel) ALFRED KEOGH, R.A.M.C.; and Colonel W. D. C. WILLIAMS, New South Wales Army Medical Corps; while Sir WILLIAM MAC CORMAC, Bart., K.C.V.O., consulting surgeon to the forces, received a Knight Commandership of the Order. The following consulting surgeons to the forces received Companionships of the Order:—Sir THOMAS NAGHTEN FITZGERALD, Kt., Sir WILLIAM THOMSON, Kt., Mr. ALFRED DOWNING FRIPP, M.V.O., Mr. GEORGE HENRY MAKINS, Mr. (now Sir) FREDERICK TREVES, M.V.O., Mr. WILLIAM WATSON CHEYNE, Mr. GEORGE LENTHAL CHEATLE, Dr. KENDAL FRANKS, and Dr. JOHN CHIENE. The following

were made Knight Commanders of the Most Distinguished Order of St. Michael and St. George:—Surgeon-General WILLIAM DEANE WILSON, A.M.S., principal medical officer in South Africa; and Colonel THOMAS JOSEPH GALLWEY, C.B., R.A.M.C., principal medical officer of the Infantry Division in South Africa; whilst Companionships of the Order were conferred upon Colonel EDMOND TOWNSEND, C.B., R.A.M.C., principal medical officer, 1st Infantry Division in South Africa; Surgeon-Lieutenant-Colonel HENRY FRANK HENSMAN, retired, late 1st Life Guards; Lieutenant-Colonel (local Colonel) ARTHUR THOMAS SLOGGETT, R.A.M.C.; Lieutenant-Colonel (local Colonel) JOHN FRANCIS WILLIAMSON, R.A.M.C.; Lieutenant-Colonel (local Colonel) PERCY HERBERT JOHNSTON, R.A.M.C.; Major (now Lieutenant-Colonel) WALTER GEORGE AUGUSTUS BEDFORD, R.A.M.C., secretary to the Principal Medical Officer in South Africa; Major GEORGE WASHINGTON BRAZIER-CREAGH, R.A.M.C.; Major FREDERICK SAMUEL HEUSTON, R.A.M.C.; Surgeon-Major (local Lieutenant-Colonel) CHARLES R. KILKELLY, Grenadier Guards; Major WILLIAM RICE EDWARDS, I.M.S.; Major HENRY ALFRED CUMMINS, R.A.M.C.; Surgeon-Lieutenant-Colonel E. B. HARTLEY, V.C., C.M.S.C.; Dr. A. A. SCOT SKIRVING (Yeomanry Hospital); Mr. J. P. BUSH (Princess Christian's Hospital); Dr. D. WALLACE (Edinburgh Hospital); Mr. H. E. CLARK (Scottish National Hospital); Mr. A. A. BOWLBY (Portland Hospital); Dr. H. H. TOOTH (Portland Hospital); and Dr. J. W. WASHBOURN (Yeomanry Hospital). The Distinguished Service Order was bestowed upon Major (now Lieutenant-Colonel) RICHARD WILLIAM FORD, R.A.M.C.; Major (now Lieutenant-Colonel) THOMAS JOSEPH O'DONNELL, R.A.M.C.; Major ROBERT JAMES LEECH FAYLE, R.A.M.C.; Major WILLIAM WATSON PIKE, R.A.M.C.; Captain ERNEST CHESTER ANDERSON, R.A.M.C.; Captain JOHN HAY CAMPBELL, R.A.M.C.; Captain PERCY JOHN PROBYN, R.A.M.C.; Captain ARTHUR WINSMORE HOOPER, R.A.M.C.; Lieutenant JOHN JOSEPH WHITWORTH PRESCOTT, R.A.M.C.; Lieutenant HENRY EDWARD MANNING DOUGLAS, V.C., R.A.M.C.; Major T. H. FIASCHI, New South Wales Army Medical Corps; Captain A. T. DUKA, A.M.C., Queensland Defence Force; Surgeon-Lieutenant (temporary Captain) C. B. KEENAN, Lord Strathcona's Corps; Surgeon-Captain R. C. PERKINS, Brabant's Horse; Surgeon-Major F. A. HOLMDEN, British South Africa Police; Captain J. J. BROWNLEE, Cape Medical Bearer Corps; Surgeon-Major W. F. F. DAVIES, Imperial Light Horse; Captain G. E. HEBERDEN, medical officer, Kimberley Light Horse; Surgeon-Major J. A. J. SMITH, Kimberley Regiment; and Major J. HYSLOP, principal medical officer, Natal Volunteers.

A second Gazette was issued in October and dealt with the same period of services as the foregoing. A Companionship of the Order of the Bath was given to Surgeon-Lieutenant-Colonel JAMES MAGILL of the Coldstream Guards and a Companionship of the Order of St. Michael and St. George to Surgeon-Major WALTER CALVERLEY BEEVOR of the Scots Guards. Companionships of the Order of the Bath were also given to Surgeon-General JAMES ALBERT CLERY, R.A.M.C.; Lieutenant-Colonel ARTHUR PATRICK O'CONNOR, R.A.M.C.; Major (now Lieutenant-Colonel) THOMAS RASHLEIGH LUCAS, R.A.M.C.; and Major (now Lieutenant-Colonel) FRANCIS AUGUSTUS BONNER DALY, R.A.M.C. Companionships of the Order of St. Michael and St. George were conferred upon Surgeon-General WILLIAM HENRY MACNAMARA, R.A.M.C.; Colonel RICHARD EXHAM, R.A.M.C.; Lieutenant-Colonel JOHN COTTER DORMAN, R.A.M.C.; Major (now Lieutenant-Colonel) HENRY JAMES PEARD, R.A.M.C.; Major SAMUEL FOSTER LOUGHEED, R.A.M.C.; Major ALEXANDER FRASER RUSSELL, R.A.M.C.; Major SINCLAIR WESTCOTT, R.A.M.C.; Major ROGER KIRKPATRICK, R.A.M.C.; Major ROBERT JOHN SHAW SIMPSON, R.A.M.C.;

Major THOMAS WILLIAM O'HARA HAMILTON, R.A.M.C.; Major SAMUEL FOSTER FREYER, R.A.M.C.; Major NICHOLAS CHARLES FERGUSON, R.A.M.C.; Major HUGH CHAMPEYNS THURSTON, R.A.M.C.; and Major OLIVER RICHARD ARCHER JULIAN, R.A.M.C. The following received the Distinguished Service Order: Major ROBERT JAMES GEDDES, R.A.M.C.; Major ALEXANDER ARTHUR SUTTON, R.A.M.C.; Captain FREDERICK SMITH, R.A.M.C.; Captain HENRY JULES PARRY, R.A.M.C.; Captain FREDERICK JOSEPH WILLIAM PORTER, R.A.M.C.; Captain HERBERT JOHN MARTIN BUIST, R.A.M.C.; Captain EDGAR MONTAGU PILCHER, R.A.M.C.; Lieutenant (now Captain) CHARLES JOHN O'GORMAN, R.A.M.C.; Lieutenant (now Captain) ROBERT STRICKLAND HANNAY FUHR, R.A.M.C.; Lieutenant GEORGE GOSLETT DELAP, R.A.M.C.; Lieutenant HOWARD ENSOR, R.A.M.C.; and Lieutenant LANGFORD NEWMAN LLOYD, R.A.M.C. Mr. GEORGE STOKER and Dr. JAMES BYRNE COLEMAN, of the Irish Hospital, and Dr. HERBERT JOHANN SCHARLIEB, of Langman's Hospital, received Companionships of the Order of St. Michael and St. George; as did also Major CHARLES STONHAM of the Yeomanry Hospital. Mr. JOHN LYNN THOMAS was made a Companion (Civil Division) of the Order of the Bath, and Mr. ROBERT HERBERT MILLS-ROBERTS a Companion of the Order of St. Michael and St. George. Both these gentlemen were connected with the Welsh Hospital. Companionships of the Order of St. Michael and St. George were also conferred upon Dr. FRANCIS BOYD of the Edinburgh Hospital; Deputy Surgeon-General HENRY CAYLEY, honorary surgeon to the King (late Indian Medical Service), of the Scottish National Hospital; and Dr. JOSEPH ERNEST GOODFELLOW CALVERLEY of the Portland National Hospital. Major W. L'ESTRANGE EAMES (Medical Corps), New South Wales Contingent, was made a Companion of the Order of the Bath. The following members of the Imperial Yeomanry received the Distinguished Service Order: Captain PERCIVAL DAVIDSON, medical officer, 5th Battalion; Captain W. J. NAISMITH, medical officer, 6th Battalion; and Captain ERNEST HOPKINSON, medical officer, 15th Battalion.

For services rendered in the operations in China Colonel J. T. B. BOOKEY, I.M.S., was appointed Companion of the Bath. The following officers were appointed to Companionships of the Order of the Indian Empire for services in the same operations: Lieutenant-Colonel W. J. R. RAINSFORD, R.A.M.C., Major J. J. C. WATSON, R.A.M.C., and Lieutenant-Colonel L. A. WADDELL, I.M.S.

For operations in West Africa the following distinctions were granted: JOHN BINNEY HAY, M.B., C.M. Edin., of the Gold Coast Medical Service, was made a Companion of the Order of St. Michael and St. George in recognition of his services in the siege of Coomassie; and Surgeon-Captain WILLIAM FLETCHER, Militia Medical Staff Corps, received the Distinguished Service Order in recognition of his services in Ashanti.

The new year's list of honours—the last, alas, to be issued by Queen VICTORIA—contained the names of THOMAS BARLOW, M.D., F.R.C.P. Lond., and WILLIAM SELBY CHURCH, M.D. Oxon., F.R.C.P. Lond., who had had baronetries conferred upon them. Among the Knight Commanders of the Order of the Bath was the name of Sir WILLIAM TURNER, M.B. Lond., F.R.C.S. Eng. & Edin., the President of the General Medical Council. In the Order of St. Michael and St. George, MAXIMILIAN FRANK SIMON, M.D. St. Andrews, late principal civil medical officer of the Straits Settlements, was made a Companion, and in the Order of the Indian Empire Major JOHN CRIMMIN, V.C., I.M.S., was made a Companion. Among those who received the honour of knighthood was HUGH ADCOCK, C.M.G., L.R.C.P. Edin., M.R.C.S. Eng., while Colonel JAMES SUTHERLAND WILKINS, I.M.S., and ARTHUR NEVF,

F.R.C.S., L.R.C.P. Edin., were decorated with the Kaisar-i-Hind medal for "public service in India." This last decoration was also conferred upon Major HERBERT EDWARD DEANE, R.A.M.C. Major THOMAS EDWARD DYSON, I.M.S., Lieutenant-Colonel JAMES McCLOUGHRY, I.M.S., and Captain EDMUND WILKINSON, I.M.S., on the KING's Birthday. On the same occasion Sir GEORGE ANDERSON CRITCHETT received his knighthood, and Lieutenant-Colonel G. H. D. GIMLETTE, I.M.S., was appointed a Companion of the Order of the Bath.

During the year the KING appointed Lord LISTER to be Sergeant-Surgeon-in-Ordinary to His Majesty and the late Sir WILLIAM MAC CORMAC, Bart., and Sir THOMAS SMITH, Bart., Honorary Sergeant-Surgeons to His Majesty.

The following appointments in the Royal Victorian Order have been made:—Sir JAMES REID, Bart., K.C.B., Knight Grand Cross; Sir RICHARD DOUGLAS POWELL, Bart., Sir THOMAS BARLOW, Bart., Sir WILLIAM BROADBENT, Bart., Deputy-Surgeon-General H. J. BLANC, Mr. FREDERICK TREVES, C.B., Sir THOMAS SMITH, Bart., and Mr. WILLIAM HENRY BENNETT, Knight Commanders; Mr. DONALD WILLIAM CHARLES HOOD, Mr. JOHN HAMMOND MORGAN, Mr. CHARLES ARTHUR MORRIS, and Mr. ALFRED DOWNING FRIPP, Commanders; and Dr. A. R. MANBY and Dr. W. AUGUSTINE ELLISON, Members of the Fourth Class of the Order.

Miss LILLIE EMMA VAHINE-É-TUA SAVILLE, L.S.A. Lond., M.D. Brux., of the London Mission, received from the KING the decoration of the Royal Red Cross in recognition of services at the International Hospital during the siege of the Legations at Peking.

Sir JAMES GRAHAM, M.A., M.D. Edin., M.B. Sydney, the Mayor of Sydney, was knighted by the Duke of Cornwall and York on May 29th at a *levée* held at Government House, Sydney.

In bringing to a close this list of representatives of the profession of healing who have done noble work in the calling to which they belong we regret—and our regret, we know, is shared by every member of the medical profession—that Surgeon-General J. JAMESON, C.B., the late Director-General of the Army Medical Staff, has not been the recipient of well-deserved honour.

#### OBITUARY.

It is necessary for us year by year to tell the tale of those who are gone from us. The present list is not so heavy as was that for the year 1900—a fact which is mainly due to the change which came over affairs in South Africa after the occupation of Pretoria. Since then we may say that, after a fashion, the war ceased and military operations took its place—namely, guerilla warfare, but there have been few set engagements. Following our usual custom, we have divided the deaths among members of the profession into classes as under.

##### *Royal Navy Medical Service.*

The senior service has lost few by death so far as medical officers are concerned. The first naval name which appears in our obituary columns is that of EDWARD HOMES CREE, M.D. Edin., M.R.C.S. Eng., L.S.A. Lond., who passed away at the advanced age of 87 years, and spent the first half of his professional life in the Royal Navy. He served through the first Chinese war and the Crimean war, and in 1869 he retired from the service with the rank of deputy inspector-general of hospitals. He had five sons, all in the medical profession, two of whom entered the Royal Navy Medical Service and three of whom entered the Army Medical Service.—HENRY PIERS, M.R.C.S. Eng., L.S.A. Lond., was educated at Guy's Hospital and entered the Naval Medical Service in 1846. He served in the Franklin relief expedition which started in 1850 and on his return served in the

West Indies. He finally became Deputy Inspector-General of Hospitals and Fleets and died in his eighty-fourth year.

##### *Army and Indian Medical Services.*

WILLIAM JOHNSTONE FYFFE, M.D. Dub., L.R.C.S. Irel., who died, aged 76 years, on May 17th, entered the Army Medical Department about 1848, and at first served in Jamaica. He afterwards served in the Crimea and later was assistant professor of medicine at Netley. About 30 years ago he retired with the rank of deputy surgeon-general and set up in practice at Clifton, where he became physician to Clifton College.—Lieutenant-Colonel DAVID CHARLES DAVIDSON, L.R.C.P., L.R.C.S. Edin., who died, aged 50 years, on May 2nd, was for some time surgeon to the Dorset County Hospital and in 1887 entered the Indian Medical Service. In 1894 he was made professor of surgery to the Sir Jamsetjee Jejeebhoy Hospital and lecturer in the Grant Medical College.—RICHARD DOMENICHETTI, M.D. Edin., who died on July 12th at the age of 78 years, graduated in medicine at Edinburgh in 1845, entered the army and served first with the 8th King's Regiment and afterwards with the Gordon Highlanders (75th Regiment). He served through the Mutiny and was left in charge of the sick and wounded in the Alum Bagh after the relief of Lucknow. After retiring from the service with the rank of deputy inspector-general he acted for 25 years as medical officer of health at Louth, Lincolnshire. In 1896 he was appointed honorary physician to Queen VICTORIA, and in 1897 he received the Queen's Jubilee medal.—Colonel G. H. FETHERSTON, M.D. Melb., who died at the age of 72 years, settled in Victoria in 1860. He was principal medical officer to the Victorian Military Forces and held in addition some important civil posts.—WILLIAM GEORGE NICHOLAS MANLEY, C.B., V.C., M.R.C.S. Eng., who died on Nov. 16th, aged 60 years, entered the army in 1855. He was sent to the Crimea and remained out there until the fall of Sebastopol. In the New Zealand war of 1864 he served with the Royal Artillery, and it was at the assault on the Gate Pah, in which he took part as a volunteer, that he performed the action—namely, that of trying to save Commander HAY and other wounded comrades—for which he was awarded the Victoria Cross. He served with the British ambulance during the Franco-German war and also through the Afghan war of 1878 and the Egyptian campaign of 1882. He retired from the army in 1884.—Surgeon-General ROBERT HARVEY, C.B., D.S.O., M.D. Aberd., F.R.C.P. Lond., was Director-General of the Indian Medical Service. He was born at Aberdeen in 1842 and received his medical education both at Glasgow and Aberdeen Universities. In 1864 he entered the Army Medical Department, but in 1865 he left this service and entered the Indian Medical Service and was at once set to work by being sent on the Bhutan campaign. After other war services he was made civil surgeon at Simla, and thenceforward held civil appointments until 1890, when he was made principal medical officer at Peshawur. After other commands he was in 1898 made Director-General of the Indian Medical Service.

##### *Hospital Physicians and Surgeons.*

The past year has caused the usual gaps in the ranks of those who serve our hospitals as physicians and surgeons. Very early in the year there died JOHN BAPTISTE POTTER, M.D. Edin., F.R.C.P. Lond., the obstetric physician to Westminster Hospital. He was the son of CIPRIANI POTTER, the well-known musician, and was educated at the Kensington Grammar School and at University College Hospital. He was but 61 years of age at the time of his death.—ARCHIBALD HAMILTON JACOB, M.D. T.C.D., F.R.C.S. Irel., who died on Jan. 12th was a well known Irish practitioner, who was for many years professor of ophthalmology in the Royal College of Surgeons in Ireland. In 1880 he was appointed oculist-in-ordinary to His Excellency the Lord Lieutenant, a

position which he continued to hold until the time of his death.—BOWATER JOHN VERNON, F.R.C.S. Eng., who was educated at Marlborough School, the Sussex County Hospital, and St. Bartholomew's Hospital, was one of the two surgeons appointed to the care of the ophthalmic wards at the latter hospital when they were first opened in 1870. He continued to discharge his duties in this position until the very day before his death. All old St. Bartholomew's men will ever cherish his memory.—LESLIE OGILVIE, M.B., C.M. Edin., M.R.C.P. Lond., who died from acute pneumonia, was in company with a few professional friends the practical founder of the Paddington Green Children's Hospital, of which he was senior physician at the time of his death. He was a man of great charm, a good linguist and devoted to literature and music.—WILLIAM JAMES FLEMING, M.D. Glasg., for many years taught clinical surgery at the Glasgow Royal Infirmary, was lecturer on surgery at Queen Margaret College, and examiner in surgery to Glasgow University. He was also surgeon to the Royal Hospital for Sick Children.—GEORGE STONE, L.R.C.P. & S. Edin., practised for many years as an aural and ophthalmic surgeon in Liverpool, being on the staff of the Liverpool Ear and Eye Infirmary.—Sir EDWIN SAUNDERS, F.R.C.S. Eng., the well-known dental surgeon, was for some 50 years dental surgeon to Queen VICTORIA. He was practically the founder of the Dental Hospital of London.—WILLIAM MOORE, M.D. Dub., F.R.C.P. Irel., who died, aged 75 years, was one of the foremost of his profession in Ireland. In 1885 he was made physician-in-ordinary to the Queen in Ireland and on Her Majesty's death he was appointed to the same post in His Majesty's household.—JOHN CAVAFY, M.D., F.R.C.P. Lond., was of Greek descent. He was educated at Brighton, University College, London, and St. George's Hospital. Besides many other appointments held at various times he was senior physician to St. George's Hospital, a post which he resigned on account of failing health in 1898.—JAMES GRIFFITH HALL, M.R.C.S. Eng., J.P., was a well-known practitioner in Swansea. At the time of his death he was consulting surgeon to the Swansea Hospital and had been for a long period surgeon to Swansea Gaol.—THOMAS BOND, F.R.C.S. Eng., will go down to posterity as a great expert in the medico-legal aspect of criminal cases. He was surgeon to the A Division of police and to Westminster Hospital.—CARSTEN HOLTHOUSE, F.R.C.S. Eng., who died at the ripe age of 91 years, was formerly senior surgeon to Westminster Hospital. At the time of his death he was senior of the very few surviving original Fellows of the Royal College of Surgeons of England. RICHARD CHARLES SHETTLÉ, M.D. St. And., M.R.C.S. Eng., practised for many years in Reading, where he was physician to the Royal Berkshire Hospital. Besides his more purely professional work he was deeply interested in electricity.—JULIUS St. THOMAS CLARKE, M.D., M.S. Lond., F.R.C.S. Eng., was senior surgeon to the Leicester Infirmary. Some eight months before his death he was shot through the sacrum by a homicidal maniac.—DAVID FRANCIS SITWELL CAHILL, M.D. Edin., carried on an extensive practice in the Border district and was consulting physician to the Berwick Dispensary.—JOHN GRIFFITH, F.R.C.S. Eng., who died at the early age of 35 years, was senior clinical ophthalmic assistant at St. Mary's Hospital and assistant surgeon to the Royal Westminster Ophthalmic Hospital.—ALFRED EDWARD AUST LAWRENCE, M.D. Aberd., who died very suddenly, was a prominent practitioner in the West of England and at the time of his death was consulting physician-accoucheur to the Bristol General Hospital.—WILLIAM LAKE ROBERTS, M.R.C.S. Eng., practised in Bradford for some 30 years and was senior honorary surgeon to the Bradford Royal Infirmary.—THOMAS VINCENT JACKSON, F.R.C.S. Edin., J.P., received his medical education at University College Hospital

and afterwards settled in Wolverhampton, where he became surgeon to the Wolverhampton and Staffordshire General Hospital.—EDWARD HARRIMAN DICKINSON, M.D. Edin., F.R.C.P. Lond., received his medical education at Edinburgh University and at St. George's Hospital. He settled in Liverpool and was physician to the David Lewis Northern Hospital for over 30 years.—ROBERT HEPBURN, L.D.S.R.C.S. Eng., who died at the age of 92 years, had a large practice as a dentist and was instrumental with Sir EDWIN SAUNDERS in founding the Dental Hospital of London.—HENRY SUTHERLAND, M.D., M.A. Oxon., who died at the age of 59 years, came of a long line of psychological physicians. He received his medical education at St. George's Hospital and at Addenbrooke's Hospital, Cambridge, as well as at Oxford where he graduated in medicine. After working under Dr. (now Sir) JAMES CRICHTON BROWNE at the Wakefield West Riding County Lunatic Asylum he came to London and was appointed lecturer on Psychological Medicine to the Westminster Hospital. He was also physician to the St. George's, Hanover-square, Dispensary. Apart from his professional work, he was a prominent Freemason and in his younger days a well-known fencer.—WILLIAM RICHARD ROGERS, M.D. Heidelb., M.R.C.P. Lond., was born in 1817. He was for 24 years physician to the Samaritan Hospital and was also consulting surgeon to the Grosvenor Hospital for Women and Children.—JAMES MANN WILLIAMSON, M.D. Edin., was educated at Shields and Edinburgh. He commenced his medical practice as resident physician to the Royal National Hospital for Consumption at Ventnor, and became in succession honorary surgeon and eventually physician to that institution. Ever since his student days he had suffered from cardiac troubles owing to rheumatic fever, and morbus cordis was the final cause of his death.—JOHN PALMER WAY, M.R.C.S. Eng., began his professional life as an apprentice to Mr. PIERCY of Portsmouth. He entered at St. Thomas's Hospital, and became M.R.C.S. in 1863. He served in the Royal Navy as assistant surgeon for three years and then settled in Portsmouth, where for some years he held the appointment of surgeon to the Royal Portsmouth Hospital.—ARCHIBALD CAMPBELL CLARK, M.D. Edin., who died on Nov. 28th, received his medical education at the University of Edinburgh. He took a special interest in psychological medicine, and was for some time at Mornington Asylum under Dr. T. S. CLOUSTON. He was next appointed medical superintendent of the Glasgow District Asylum at Bothwell, and finally he was elected superintendent of the new asylum for the county of Lanark which was to be built at Hartwood. This building was erected and equipped under his personal supervision. Dr. CLARK wrote a good deal upon the subject of insanity, his chief work being "A Clinical Manual of Mental Diseases," published in 1897.—By the death of Sir WILLIAM MAC CORMAC, Bart., K.C.B., K.C.V.O., F.R.C.S. Eng. and Irel., &c., who passed away quite suddenly at Bath upon Dec. 4th, the profession of medicine loses one of its foremost members. Sir WILLIAM MAC CORMAC's career has been so recently set forth in our columns that we need not recapitulate it here. He held the post of President of the Royal College of Surgeons of England for the unprecedented period of five years in succession.

#### *State and Municipal Officials.*

Of medical men who served the State in other capacities than a purely professional one we may mention CHARLES KEARNS DEANE TANNER, M.D. R.U.I., M.P. Dr. Tanner, who was born in 1850, was educated at Winchester School, Paris, Queen's College, Cork, and the Universities of Leipzig and Berlin. He was for some time physician to several of the Cork hospitals, but practically retired from practice upon taking up politics. His behaviour in the House of Commons was much to be regretted, for in private life he was a most

kindly companion and was popular among his friends. He sat first as a Nationalist and afterwards as an Anti-Parnellite for the Mid-division of county Cork.—JAMES AITKEN MYRTLE, M.D. Edin., was a well-known practitioner of Harrogate. He was educated at Winchester School and Edinburgh University, where he graduated M.B. in 1882. He settled in Harrogate and took a great interest in local politics, being on the town council for five years, while at the time of his death he was serving his second year of office as mayor.—Sir JAMES WILSON AGNEW, M.D. Glasg., was a notable practitioner of Hobart. From 1877 to 1881 he was a member of the Legislative Council of Tasmania, while from 1886 to 1887 he was Premier and Chief Secretary.—JOHN EDWIN SCOWCROFT, M.D. St. And., J.P., studied medicine at the Manchester and Liverpool schools of medicine and commenced practice in Bolton. He had always taken a deep interest in municipal matters and was Mayor of Bolton at the time of his death and a magistrate for the county borough.—JOHN SAMUEL SLATER, M.R.C.S. Eng., J.P., was educated at St. Thomas's Hospital. He commenced practice in Evesham in 1872, was elected a member of the town council in 1879, and in November, 1899, he was elected as mayor.—HENRY WILLIAM LIVETT, M.R.C.S. Eng., J.P., who died at the age of 87 years, was educated at St. Bartholomew's Hospital and at Paris. He was a prominent practitioner and citizen of Wells, in which town he twice filled the office of mayor.

#### *Distinguished Foreign Medical Men.*

Among eminent medical men belonging to other nationalities than our own we must mention the name of the greatly loved and esteemed Professor POTAIN. He died quite suddenly, at the age of 75 years, on Jan. 5th, and scarcely six months after he had delivered his last lecture at the Charity Hospital in Paris. His death is an irreparable loss to the Paris Faculty of Medicine, and few of our profession have been held in greater honour or been more loved.—Professor W. H. HEINEKE, who died in June, was a prominent German surgeon. He had held the chair of Clinical Surgery at the University of Erlangen for 33 years.—Germany also sustained a bitter loss by the death of Professor MAX VON PETTENKOFER, which occurred in Munich on Feb. 10th. His hygienic work is known to all the world.—Hungarian medicine has to mourn the death of Professor JOSEPH FODOR, M.D., of Budapest. He was born in 1843 and was a follower of VON PETTENKOFER, whose ideas upon sanitation he introduced into Hungary.—Italy is the poorer by the death of Professor BIZZOZERO, Professor of General Pathology in the University of Turin. He was a pupil of VIRCHOW, who used to call him, "My best pupil." He died on March 19th owing to the effects of an injury to his leg and a subsequently necessary amputation.

#### *Civilians.*

THOMAS TAYLOR, M.R.C.S. Eng., who died on Dec. 23rd, 1900, was born in 1819, and was one of the few practitioners left who began their professional careers under the old apprenticeship system. When 15 years of age he was apprenticed to Mr. HESTER of Abingdon and afterwards he entered at St. Bartholomew's Hospital. He qualified in 1842 and soon after settled down in practice at Bocking. He was local secretary of the Royal Medical Benevolent College, and apart from his profession took a deep interest in gardening.—CHARLES ROBERTS, M.R.C.S. Eng., who died very suddenly in Victoria Station, London, on Jan. 7th, was educated at St. George's Hospital, and was for many years a prominent practitioner in Uxbridge.—JAMES EDWARD PRICHARD, M.B. Oxon., M.R.C.S. Eng., was a son of the late AUGUSTIN PRICHARD of Clifton. JAMES PRICHARD was educated at Oxford and at University College Hospital, London. He practised in Bristol and at the time of his death was surgeon

to H.M. prison at Horfield.—BARON ALFRED RUGG, L.R.C.P. Lond., M.R.C.S. Eng., was educated at University College Hospital. In 1875 he settled down at Wood Green and was surgeon to the Wood Green Cottage Hospital.—JAMES NICOL, M.D. Glasg., J.P., was born in 1815 and had practised at Llandudno since 1858. Of this place he was medical officer of health for some 20 years and made a special study of the climate and meteorology of the district.—JAMES HOOPER, M.R.C.S. Eng., who died in his ninety-sixth year, was educated at Eton College, where he was a contemporary of W. E. GLADSTONE. He was present at the funeral of GEORGE III. and studied medicine at University College Hospital. He practised at Ford and later at Marshfield, near Bath, at which place he continued to work until he was 90 years of age.—The Rev. RICHARD PRIOR WINTLE, M.R.C.S., was a son of Dr. F. T. WINTLE of Headington. He was educated at St. George's Hospital, but only practised the medical profession for a few years, being admitted to Holy Orders in 1880. He died in his sixty-first year.—GEORGE HANBY DE'ATH, L.R.C.P. Lond., M.R.C.S. Eng., was educated at Westminster School and at Guy's Hospital. He qualified in 1884 and on the sudden death of his father in 1886 succeeded to his practice in Buckingham. He was coroner for the Winslow division of Bucks and medical officer of health of the borough of Buckingham. He was a good public speaker and an admirable amateur actor.—JOHN CONNELL, M.D., F.R.C.P. Edin., was for many years a prominent and popular practitioner on Tweedside. He commenced practice at Melrose, but moved after a few years to Peebles. He was a fluent speaker and held many appointments, such as surgeon to the county gaol, medical referee under the Workmen's Compensation Act, and local medical officer to the Board of Health. He was a good scholar and took a special interest in education. Among others of those who have passed away we must mention the names of IVOR AJAX LEWIS, M.R.C.S. Eng., J.P., of Porth; JOHN ARCHIBALD LORIMER, M.R.C.S. Eng., of Farnham, who met his death through a carriage accident; CHARLES HITCHMAN BRADDON, M.D. St. And., of Manchester; JOHN DAVID WILLIAMS, M.D., C.M. Edin., of Cardiff, who died from typhoid fever at the early age of 36 years; HENRY LLEWELLYN WILLIAMS, M.D. Edin., a well-known practitioner in Kensington; EDMUND DE LA CHEROIS, M.D. Dub., who, like his fellow practitioner JOHN LORIMER, died from the result of a carriage accident; FRANCIS WILLIAM WARRINGTON, M.D. St. And., J.P., of Congleton; HERBERT RICHARD BRACEY, M.R.C.S. Eng., of Birmingham; THOMAS LIVINGSTONE, M.D. Glasg., J.P., who practised at Stanhope, co. Durham, and was chairman of the school board; CHARLES DAGNALL CLARK, M.B. Lond., of Sydney, N.S.W.; EUGÈNE GODDARD, M.D. Durh., who died at the age of 60 years from acute peritonitis and who was well known as a practitioner in the north of London; JOHN HALLILAY, M.R.C.S. Eng., who practised in Leeds for nearly 50 years; ALFRED HUTCHISON SMEE, M.R.C.S. Eng., chief medical officer of the Gresham Life Assurance Society; ROBERT BARBOUR MCKELVIE, M.D. Glasg., of Oban, who for 26 years lived the laborious life of a medical practitioner in the West Highlands, and was the donor of the McKelvie Isolation Hospital to Oban; DAVID RITCHIE PEARSON, M.D. Edin., M.R.C.S. Eng., served for two years in India with the Rifle Brigade, settled in Kensington in 1863, and was one of the founders of the Kensington Dispensary; JENKIN LLOYD, M.B., C.M. Glasg., who died on Nov. 20th after a few hours' illness, practised at Bethesda, Carnarvonshire, and was a good Welsh scholar and an excellent bard.

The war against sickness and death has many points comparable to that of the war now being waged in South Africa against the King's enemies. Of the many pathetic incidents which have occurred there few can compare with that at

Brakenlaagte. Colonel BENSON lay dying with WOOLLS-SAMPSON, his brother-in-arms, bending over him. "Good-bye, old boy," said BENSON, "no more night marching now; it's all day." So may the weary practitioner who has fought his last fight say. "No more night work now; it's all day."

## Annotations.

"Ne quid nims."

### THE PRINCE OF WALES'S HOSPITAL FUND FOR LONDON.

At the distribution meeting of the Council of this Fund which was held on Dec. 21st, at York House, St. James's, S.W., when the Prince of Wales occupied the chair, Mr. J. W. Craggs, in the absence of Lord Rothschild, presented the financial statement which showed that the total receipts for 1901 up to Dec. 16th were about £53,000. The expenditure was £1530, showing a net balance of something like £51,470. The balance from last year being £174,225 3s. 7d., the grand total for the year 1901 is therefore more than £225,000. These figures are exclusive of the sums received for the coronation gift. The League of Mercy has this year contributed £7000, an increase of £1000 over last year. The sum recommended for division among hospitals is £50,000, being £1000 more than the previous year. £1000 will also be distributed among convalescent homes.

### SMALL-POX "CONTACTS" IN ST. PANCRAS.

At a meeting of the St. Pancras Borough Council held on Dec. 18th the Public Health Committee presented a report from Dr. J. F. J. Sykes, the medical officer of health. The report dealt with the outbreak of small-pox. Since Oct. 6th all cases of chicken-pox have had to be compulsorily notified. During a period of nine weeks 115 cases were notified as chicken-pox and of these 115 cases two were subsequently found to be cases of small-pox. The report considered the cases of "contacts" to be a matter most difficult to deal with. "Contacts" spread the disease both by their persons and clothing. They were dangerous if not rendered immune, but even in their case the liberty of the subject was not lightly to be disregarded. The methods open to adoption were four: (1) liberty; (2) exclusion; (3) seclusion; and (4) quarantine. Of these, liberty of a person who had been in contact with small-pox could only be allowed with safety after the person had been carefully washed, including his hair and nails, had had all his personal clothing removed and steamed in a disinfecting chamber, had been revaccinated, and had undertaken to report his condition daily for a fortnight. Baths and disinfection apparatus available for such cases existed, having been provided by the Marylebone Borough Council under the Cleansing of Persons Act, 1897. No compulsion could be exercised over a "contact." Exclusion simply from offices or other business premises fell hardly on small wage-earners, and as "contacts" might associate with other persons elsewhere the public was in no way benefited. Seclusion at home varied in degree according to the amount of separation available for persons and families. The whole house might have to be secluded even though many families, only one of which was infected, occupied it. Quarantine implied a quarantine station in which "contacts" might be isolated. The report did not make any definite recommendation as to which of these four methods should be employed, but it evidently implied that the two last-mentioned were the most valuable, although "liberty" appeared to be safe if the "contact" would submit to the regulations. At present no compulsion could be exercised over

"contacts," but on Nov. 27th the borough council resolved that a representation should be made to the President of the Local Government Board asking him to introduce into Parliament with all expedition a Bill authorising the sanitary authorities to exercise compulsion over the persons and clothing of infected vagrants; they would then be treated either by seclusion or by quarantine. The report, we are glad to say, was adopted. The question of compulsion is an exceedingly difficult one with which to deal. The Englishman is quite accustomed to compulsion which only deals with his pocket. He is grumblingly ready to pay compulsory rates even for objects of which he does not approve—as, for instance, the school board rate in the case of some, or the war taxes in that of others. But any compulsory regulation which affects his person would meet with grave disapproval. Compulsion, however, is an excellent thing to have ready and if persuasion will not do, although in the vast majority of cases we think it will, we hope that Parliament will grant the necessary powers for other steps to be taken.

### A CASE OF ABNORMAL ERUPTION OF A MANDIBULAR CANINE.

In the current issue of the *Journal of the British Dental Association* Mr. Dencer Whittles records a case of abnormal eruption of a mandibular canine. The patient, a girl, at the age of six years suffered from an acute suppurative periodontitis in connexion with the right mandibular deciduous incisors and canine. A sinus resulted which opened under the chin. Six months subsequently a sequestrum was removed through the sinus, and the wound healed, leaving a depressed scar. At the age of 10 years the right mandibular canine erupted through the scar and was eventually removed. The root of the tooth was considerably distorted, owing probably to some displacement of the tooth sac at the time of the primary trouble. A similar case to the above was recorded by Mr. C. Truman in the St. Thomas's Hospital Reports, 1893. In this patient a canine and a premolar made their way through the track of the sinus and appeared under the chin.

### THE DISTRIBUTION OF PLAGUE.

A TELEGRAM from the Governor of the Mauritius received at the Colonial Office on Dec. 20th states that for the week ending Dec. 19th there were 46 cases of bubonic plague, of which 21 were fatal. As regards Egypt, during the week ending Dec. 15th only one case of plague has been reported throughout all Egypt. It occurred at Zeftah in the person of a native who had been isolated on Dec. 7th.

At the Central Criminal Court on Dec. 20th Frank and Edith Jackson were convicted under the Criminal Law Amendment Act and sentenced—the male prisoner to 15 years' penal servitude and the female to seven years'. The forensic, psychological, and moral aspects of this case being remarkable it may be our unpleasant duty to return to the subject.

THE death is announced of Sir J. Henry Gilbert at Harpenden, Herts, at the age of 84 years. The veteran agricultural chemist has thus outlived his great partner in research, Sir John Bennet Lawes—whose death was announced in THE LANCET of Sept. 8th, 1900—by 15 months.

THE death is announced of Mr. H. G. Madan, Senior Fellow of Queen's College, Oxford. He was for some time chemistry master at Eton College, and was a most admirable teacher.

GIFT TO AYR COUNTY HOSPITAL.—The sum of £140, the proceeds of the Ayr Charity Cup football competition of last season, has been paid to the Ayr County Hospital

## Looking Back.

FROM

THE LANCET, SUNDAY, DEC. 28, 1823.

### TABLE TALK.

*Musical Phenomenon.*—Paris at this moment possesses a real phenomenon, in a young Hungarian, aged eleven years, named Leist. This child already displays talents of the first order as a pianist; but the execution of young Leist is not only distinguished for rapidity of fingering, which is what is admired in a number of performers; he unites to a perfection of lightness and firmness of hand, an expression which has been wanting in other performers, whose reputation is, nevertheless, very high. This, however, is what is least astonishing in the talents of this extraordinary child. He composes in the style of the greatest masters, and he improves on lessons given him with a facility so much the more marvellous as the force and grace of ideas never fail him. Since Mozart, who astonished several Courts of Europe at the age of eight years, the musical world has certainly witnessed nothing so surprising as young Leist. We must not forget to notice a characteristic feature, which completes his fame as a real prodigy, which is, that having only recently begun to learn the French language, he already expresses himself in it with a distinctness and sometimes with an elegance which would do credit to many youths of 16 or 18 years of age.—*Paris Paper.*<sup>1</sup>

### TO CORRESPONDENTS.

We have received several letters from Students belonging to the class of Mr. Charles Bell, complaining of the noisy and childish behaviour of some of the pupils during lecture; so great has been the annoyance, that Mr. Bell, twice in the last week, was obliged to address the gentlemen on the subject. If this interruption should be repeated, Mr. Bell, in justice to his *intelligent* hearers, is called upon to take the most decisive measures to abate what has now become an intolerable nuisance. The Student who can be inattentive to a lecture delivered by Mr. Charles Bell, can have but little regard for either his professional character, or intellectual improvement.

## THE PLAGUE IN INDIA.

BY ALEX. GRAHAM-SIMPSON.

### III.—PLAGUE DUTY AND WHAT IT MEANS.<sup>2</sup>

"PLAGUE duty" is a very wide and a very vague term. Beyond a hazy notion that the officers, medical, military, and civil, who are engaged in it have in some way to grapple with the scourge which has afflicted India for four years few people know what it means. And they would be little likely to find out unless they cared to go some day with a *plague walla* on his rounds. Take, for example, the work of the district officer, the *burra sahib* of a ward. He has to advise all below him and must report cases of insanitary buildings and drains to the district health officer. His duties, generally speaking, consist in making himself thoroughly acquainted with the area under his control and seeing that his establishment is sufficient and is duly distributed. He must organise local committees, see

to the distribution of work among members so that the whole of his district is kept under regular observation, and arrange for periodical committee meetings to hear grievances and discuss difficulties. He must make notes of the work done by each committee member and watch that no committee is neglecting its work. Immediate information has to be obtained by him through his organisation of all plague cases. He must make, or cause to be made, a register of every house in his ward. In this book every death is registered. If from plague the entry is made in red ink and in black ink when due to other causes. This is most important and special attention has to be paid to it. The cause of death as shown in the cemetery returns is often unreliable, so when a particular house or street is registered with an unusual number of deaths close attention is directed to the case and in nine cases out of ten it is shown that a considerable amount of the extra mortality is due to plague. Information for this sombre record has therefore to be gathered not only from the cemetery returns but from local committees and from information obtained from the district and health department staffs. Then, too, the district officer has to watch the mortality among rats. Directly an increase of the vermin occurs in any quarter he must see that every effort is made to destroy them.

#### *Work of Disinfection.*

Any place in which dead rats are discovered has to be disinfected at once. Nor does that end the list of tasks in what is known as "plague duty." He who would be worthy of his pay must see that patients with their relatives and dependents are removed from infected dwellings. Infected houses have to be disinfected. When a death is known to be due to plague there is no hesitation in disinfecting; but when the cause is doubtful care has to be taken that whatever error there be is on the side of safety. The *plague walla* has to see that disinfectants are properly used in such cases and that no locality is left uncared for in which the germ, lying dormant, may spring up afresh when conditions prove more favourable. The camps in his ward must be supervised and watched lest they become insanitary. He has to advise on questions of caste, to see that proper passes are given to people going up-country, to watch that all returns are punctually made, and forward to headquarters a weekly report of progress.

#### *At the Central District Office.*

All this he is expected to do. Now as to the manner in which he does it. A drive more or less long in his own vehicle or a *tacca gharry* some time before seven o'clock in the morning brings him to his central office, probably a *chuppar* (mat) shed to which the reports of the volunteers assisting him have been sent, and where a clerk has taken the record of all the cases of death from plague, or from what is suspected to be plague, in the district. These particulars may also have been furnished by the police or by the cemetery authorities. When received they are divided into sub-districts, and to each of the volunteers who have been put in charge of these subdivisions is given by the clerk a slip with addresses to which visits must be paid. There may be only three or four houses on a list, but rounds are long, as a rule, and four may be a hard morning's work, especially for the volunteer who has his private business to attend to afterwards.

#### *A Morning Round.—The Start.*

Let us accompany the plague officer on the round which he has selected. A drive from the central office through narrow streets, shaving past lethargic bullocks drawing cumbrous overloaded wagons, nearly running down hens and pariah dogs, never to speak of the superabundant juvenile population that persists in wandering into the middle of the road, brings us at last to our destination. It is in a small street where the houses are low and dark and close together. The inhabitants turn out to see us and the *plague Walla* hails them cheerfully, for they must be kept in good humour. The house sought is closed and the people, probably before it has been reached, protest that all the occupants have gone away. There is such earnestness in their manner that suspicion is aroused in the breast of him who hears. He asks how the occupants departed, when they departed, and whether they took all their possessions with them. "Yes," he is informed; "the case was assuredly plague and the relatives thought it best to leave the premises. They have gone up country"—to "their own country," as it is broadly defined—"but they did not take all their things

<sup>1</sup> The above interesting extract undoubtedly has reference to Liszt, concerning whom there appears in "Blackie's Modern Cyclopædia," vol. v., a biographical note as follows:—

"*LISZT, ABRE FRANZ*, distinguished pianist and composer, was born in Hungary in 1811, and died in 1886. He made his first public appearance in his ninth year; studied in Vienna and Paris; produced an opera in 1825, and became director of the Court Theatre at Weimar in 1849. This gave him the opportunity to introduce the music of Wagner, Berlioz, Schuman, and the writers of what is known as 'the music of the future.' In 1861 he took up his residence in Rome, where he joined the priesthood. In 1870 he became director of the Conservatory of Music at Pest. His chief works are the *Faust* and *Dante* symphonies and the oratorios *St. Elizabeth* and *Christus*."

<sup>2</sup> Nos. I. and II. were published in THE LANCET of Dec. 14th (p. 1692) and Dec. 21st (p. 1753), 1901.

with them." The officer gently, but firmly, says that he must get into the house, and that, after he has been in, he must close it so that no one else shall enter.

#### *Argument and its Effect.*

He explains for the thousandth time the why and the wherefore of it all and when the people look sulky at his *zoolum* (tyranny) he asks if they think that he comes down there for the pleasure of annoying them—if they think there is any joy in ferreting round their evil-smelling district. This has its effect. The faces of the crowd—and it is marvellous how large a crowd can appear from half a dozen houses on such an occasion—brighten wonderfully. He has appealed to a degree of their reason that can be reached. They admit that, after all, there cannot be pleasure in it even for him, and, having admitted so much, they wonder what other reason if not for their good he can have in coming among them. Presently, just before the rickety lock is forced, the owner comes forward from the crowd. He does not want his lock spoiled and offers the aid of a key. The crowd, who had so far assisted him, now chaff him because of the failure of the *ruse* and he himself enters into their fun. He is not afraid of plague, he says, "he cannot get it." The man walks with a stick. On his legs and arms are what appear to be deep-seated tuberculous eruptions. His wife helps him as he walks. After some conversation with the neighbours—"Full of syphilis," says the officer, "and he's learnt, somehow, that he is immune." A couple of men by this time have entered the house, and, following their chief, they sprinkle carbolic liberally. Some rags—the owner calls them *kupra*, or clothing—are found in the place. These are taken out and burned, kerosine being used to aid in their destruction. Compensation to the extent of several annas is given to the syphilitic one, and, being now in a good humour, with a little persuasion he and his people go off to a segregation camp.

#### *Down among the Fisher-folk.*

On the address slip the next place to be visited is possibly down among the fisher-folk, so thither we go. To the right there, where the sea comes rippling up to the *charls*, they live. We might know that they were fisher-folk by the smell, if there were no nets and broken oars and bits of rotten rope to tell us of it. They wear a cap like a fez without the tassel on top. It comes down well on their shaven heads. Above the brow a piece has been taken out. Someone says that they are the descendants of the pirates of former days. Very likely it is true. They still retain a certain self-possession and bold carelessness of manner that may be the gift of their bold ancestors or may be the natural outcome of their occupation in the free air away from the hovels where on shore they dwell. They have got used to the *plague walla* by now and they will talk and jest with him, though at one time they were troublesome. Look at them—a thick crush for so small an area; but they are nevertheless content with their lot.

#### *A Vain Search.*

We wander round, asking first one person and then another where the specified individual is to be found. The sun begins to be very hot, and in these narrow, ill-smelling lanes it is reflected again and again from the white walls of the houses. The head man—said to be very rich, though there is no outward and visible sign of his wealth beyond the amplitude of his presence—is called upon and he declares that there is no such person in the locality. As for numbers he knows nothing about them. So twenty minutes or half an hour is wasted and we decide to proceed to the next place of call. But that is worse. A cluster of huts stands on the slope of a creek from which the water has retreated and the muddy basin is noisome in the extreme. Several of the little, low buildings have been vacated. If we had not seen it with our own eyes we would scarcely have believed it possible that any human being could have lived in them—dark, filthy dens as they are, with scarcely a rat-hole for light and ventilation and the rooms not eight feet square.

#### *The Benefit of Plague.*

Plague has not been an unmitigated evil in India if it has caused such places as this to be cleared. We proceed through passages which must be traversed sideways. Our heads hit against hard things and are only saved by the

strength of an Elwood *topee*. Our faces graze some filthy rag that seems as if the germs of all disease had harboured upon it. Through a door we crouch to enter. Two figures can dimly be seen, one prostrate, the other bending over it. When our eyes grow accustomed to the light we see that the prone figure is that of a girl in the last stage of disease. We retire and the medical man who has been following goes in to the sufferer. When he emerges he declares the disease to be plague and tells us, what we already suspected, that ere many hours the patient will be dead. Plague hospitals can do nothing for her now—the case has been concealed too long. Afterwards the people in the place will be given the alternative of segregation or inoculation. In all probability they will choose the latter, for to them this dungeon is, after all, their home. Their forefathers never had light and air fit to breathe—why should they? What was good enough for those gone before is surely good enough for them. No amount of argument will change their view.

#### *Real and Ideal.*

Once more in the street and we press on to another house some five minutes' drive from the scene of the last visit. Like most places in the East it would look exceedingly well in a picture. To the observer in a poetical mood it might even suggest the Arabian Nights. But on the spot it is impossible to be poetical. Close contact with the lower strata of native life will not permit any flights of fancy. So we pass gingerly over the open gutter in a damp yard to which a diminutive door admits us. In reply to questions carefully asked the people state that there is a sick man upstairs. Upstairs we go with handkerchiefs close pressed to our noses. Sure enough, in a room—a closet—lies a man attended by his wife. The light is not so scarce that we cannot see he is ill—very ill. We stand over him. The plague officer stoops low to make inspection. "Looks queer," he remarks; "The doctor will be here in a minute. Let us wait." While waiting he talks kindly to the woman who watches with the keenest suspicion and apprehension our every movement. By-and-by the doctor puts in an appearance. Going down on his knees he examines the patient. "This is not plague," he remarks on rising, "it is small-pox."

Before the morning round is completed we have discovered typhoid fever and cholera and probably breathed more genuine disease-laden air than the average Londoner will take into his lungs in the course of his existence. Health reports and plague blue-books look so simple and unattractive—it is wonderful how much lies behind them.

## Pharmacological Notes.

### THE ALKALOIDS OF IPECACUANHA.

Paul and Cownley<sup>1</sup> have summarised the results of their chemical investigation of ipecacuanha. They have examined the official or Brazilian root, also the Carthagena or New Granada root, and in each case they have isolated three alkaloids—viz., emetine, cephaeline, and psychotrine. The relative proportion of these alkaloids found in the different roots is of importance on account of their physiological effects. Both emetine and cephaeline have a powerful emetic action, but it has been shown by Dr. R. B. Wild that the emetic dose of emetine is double that of cephaeline; in other words, cephaeline is the stronger emetic. It is given in doses of from five to 10 milligrammes. Cephaeline, however, nauseates twice as much as does emetine. Emetine is a better expectorant than cephaeline. In acute fever and catarrh, where vomiting is not required, emetine in small doses is likely to prove of considerable value; it may be given as an emetic in doses of from 10 to 20 milligrammes when a more depressing action is required. The total quantity of alkaloid in the two varieties of drug is about 2 per cent., or rather more in the Carthagena root, but it is of the utmost importance to note that the proportions of emetine and cephaeline are so different that the drugs cannot be considered as interchangeable. The figures given are in

<sup>1</sup> American Journal of Pharmacy, vol. lxxiii., p. 57 et seq.

percentages and so represent the proportions of each alkaloid present in 100 parts of the total alkaloid.

Alkaloid.	Brazilian (official) root.	Carthagena root.
Emetine ... ..	72.14	40.5
Cephaeline... ..	25.87	56.8
Psychotrine ... ..	1.99	2.7

The stem of the Brazilian ipecacuanha contains approximately the same proportions as the root; the percentages are 65.6, 32.8, and 1.6 respectively of the alkaloids in the order named. There is a preparation on the market known as "de-emetinised" ipecacuanha. Paul and Cownley have found it to contain as much as 0.5 per cent. of total alkaloids. They have also found that ipecacuanha contains a crystalline saponin-like constituent of the nature of a glucoside, which in doses of 0.25 gramme has no emetic action.

#### APPLICATIONS FOR SURGEONS' HANDS.

The following hints for the treatment of surgeons' hands, taken from an Austrian source,<sup>2</sup> may prove useful. To protect the hands against the action of corrosive disinfectants—e.g., carbolic acid and corrosive sublimate—washing with water is not enough. After using carbolic lotion it is best to wash with alcohol, and after sublimate with solution of common salt, in each case soaping the hands thoroughly afterwards. It is a good plan to mix a teaspoonful of borax with the lather and after the hands are dry to rub in a little hydrous wool-fat. Unpleasant smells, as of iodoform, creasote, guaiacol, and similar odorous drugs, are removed by washing with linseed meal, or mustard-meal, and water. Other substances also are recommended for this purpose—e.g., coffee, turpentine, tar-water, and ethereal oils. In the case of iodoform the smell can be easily removed by washing with powdered ergot of rye. Chapped hands are avoided by rubbing with a mixture of glycerin and rose-water, or glycerin, boric acid, and soft petroleum. The following application is suggested for healing cuts: menthol, 0.75 part; salol, 1.5 parts; olive oil, 15 parts; hydrous wool-fat, 45 parts.

## SICK AND OBSTETRIC NURSES BILL.

THE following is the text of Dr. A. McCook Weir's Sick and Obstetric Nurses Bill:—

Whereas it is expedient to abolish the practice of midwifery by ignorant and incompetent persons calling themselves midwives, and to protect poor parturient women and their infants from such persons, and to make better provision for the nursing of the sick and parturient poor and their children in England and Wales:—

*Be it enacted, &c.,*

1. This Bill shall be known and cited as the "Sick and Obstetric Nurses Bill, 1898."

2. On and after the First day of January, Eighteen Hundred and Ninety, this Act may be adopted by any duly constituted local authority, such as boards of guardians, county, district, and parish councils, or by voluntary nursing associations acting independently of, or in conjunction with, any of the aforesaid authorities who shall have power individually and collectively to enforce the provisions of this Act in their respective districts.

3. On and after the date of the passing of this Act and its adoption by any of the authorities herein named, it shall be unlawful for any person (male or female) to assume the title of midwife, or to practise as such, or to act as a sick or obstetric nurse, for gain or otherwise, without the supervision and control of a fully-qualified and registered medical practitioner. Any person infringing this provision and neglecting or refusing to send for medical or surgical aid at or immediately after a confinement shall be liable to a fine of £10 or imprisonment for a month in default.

4. On the adoption of this Act by any of the authorities herein specified it shall be incumbent upon them to employ a sufficient number of sick and obstetric nurses to meet the requirements of the poor and working-class population of their respective districts, and no woman already in practice as a midwife, sick, or monthly nurse shall be eligible for employment by any authority herein named unless she can produce a certificate of competence from a duly recognised teaching authority that she is proficient in the art of sick and obstetric nursing. And any attempt to evade this provision shall be deemed an offence against this Act, and the person so offending shall be liable to a fine of £5, or to a month's imprisonment in default, in a court of summary jurisdiction.

5. Any of the authorities named in Clause 2 of this Act, and who adopt the same, shall be held responsible for its due administration to the Lords of the Council or the Local Government Board, provided the

latter have already jurisdiction and authority in that behalf, and *tate* *ally* every adopting authority shall (a) keep a register of such nurses easily accessible at all times to the public, and (b) shall provide for the payment of their nurses either by means of the public rates or by voluntary subscriptions and donations, and by the contributions of the beneficiaries under this Act, or in part by these and by grants in aid from the funds administered by these respective authorities; and (c) in order to make due provision for the sick and parturient poor and their children it shall be incumbent upon boards of guardians in default of other authority to adopt and carry out the provisions of this Act in their respective unions and to vote the necessary funds, or to make grants in aid to voluntary nursing associations to meet the expenses of the provisions of this Act. The medical fees under this section to be the same as under Section 8 of this Act.

6. It shall be the duty of any of the adopting authorities to keep a complete list (to be revised from time to time) of the medical men practising midwifery in their respective districts, and in the case of Voluntary Nursing Associations adopting this Act it shall be incumbent upon them not only to keep a complete list of the medical men but to invite them to join their associations and their executive committees. And every woman shall have the right under this Act to choose her own medical man, whether she contribute to the funds of the association or not, and any sick or obstetric nurse trying to influence any patient under her charge in favour of any particular medical man shall be deemed to be guilty of an offence under this Act and shall be reprimanded by the administrative authority for a first offence and dismissed their service for any subsequent repetition of the offence. And for any offence by any member of the medical staff of the administrative authority, or of a voluntary nursing association, the medical officer shall be suspended until due inquiry shall be made into the case by the General Medical Council, provided always that such offence be of the nature of neglect or maltreatment of any given patient, or of making a false or unjustifiable charge against any sick or obstetric nurse or member of the medical staff. And it shall be a further duty of the adopting authority or voluntary association to take steps by advertisement or otherwise to make known the benefits of the association to the poor of the district, and, if necessary, to employ and pay a secretary to collect patients' subscriptions, and to canvass for contributions and donations to the funds of the association.

7. It shall be an offence under this Act for any woman, whether acting as sick or obstetric nurse, and registered as such or otherwise, to advise or prescribe or to administer a noxious drug<sup>1</sup> or to use any surgical instrument beyond those necessary to her calling as a sick or obstetric nurse, on any patient (whether man, woman, or child) under her care, or to sign any death certificate or certificate of still birth, or of illness for any club or benefit society, under any pretence whatever, and if convicted of any breach of this provision shall be adjudged guilty of a misdemeanour and shall be liable to imprisonment for a period of three months without the option of a fine and to dismissal by the administrative authority under which she is acting. Proceedings may be taken under this section by the police, the registrar of births and deaths, and the Registrar-General, as well as by the administrative authority under this Act before any court of petty sessions in the district where the offence was committed.

8. Where it is incumbent upon boards of guardians to adopt and carry out the provisions of this Act, their relieving officers must make themselves acquainted with the poor women in their respective districts who shall require the assistance of the medical officer and the obstetric nurse, and shall submit a list of all such women, together with a statement of their own and their husband's earnings, to their respective boards, who shall consider the same and forthwith grant orders on their medical officers, or on any other duly qualified and registered medical man within their jurisdiction, always having due regard to the patient's convenience; and in the event of great poverty, short of actual destitution, the Board shall authorise their relieving officer to grant confinement orders on both doctor and nurse; and in the case of those whose income is precarious, or who are in temporary difficulties, to grant confinement orders "on loan" until such time as the parties can refund the same. And the issue and the acceptance of these orders shall be no bar to the exercise of their social and political rights and privileges by the recipients. All fees payable under this section by boards of guardians, or by the authorities named in Section 5 of this Act, shall be in accordance with the consolidated orders in reference to Poor-law midwifery practice, together with mileage beyond the distance of one mile from the residence of the medical man or their medical officer, as the case may be.

9. Sick nurses shall in all cases act independently of and in no case undertake the duties of obstetric nurses as laid down in the schedule hereto, but shall be otherwise subject to the same supervision and control as obstetric nurses.

*Schedule A. Clause 2.*—For the adoption of this Act it will suffice to give notice for three weeks in the columns of the local press and written notice to the central authority by the clerk or secretary to the authorities named in this clause.

*Schedule B. Clause 3.*—The prosecuting authority in this shall be the same as in Clause 7, and the court, the police-court, or petty sessional court of the district in which the offence was committed.

*Schedule C. Clause 4.*—All sick nurses under this Act must have at least six months' training in medical and surgical nursing in a recognised metropolitan or provincial general hospital, and must hold a certificate from the teaching staff setting forth that the person named therein is competent to undertake the nursing of medical and surgical cases according to modern methods, and that she has been examined both theoretically by written papers as well as practically at the bedside, not only in the subjects named, but also in cooking for and feeding the sick, according to instructions laid down in that behalf by her examiners. Nurses with three years' 18 months, and six months' training respectively shall be certified after examinations as *first, second, and third grade*, and the position and pay of each grade shall be according to the following scale:—

First grade nurses, salary £100 per annum, to wear full dark-blue costume, as worn by Jubilee nurses.	
Second " " " £80 " " to wear grey costume.	
Third " " " £60 " " to wear plain dress, with nurse's head-dress.	

<sup>2</sup> *Zeitschrift des Allgemeinen Oesterreichischen Apotheker-Vereines, Band liv., p. 1156.*

<sup>1</sup> Vide appendix.

Sick nurses must not accept fees, gratuities, or extra remuneration from any patient, or relation, or friend, or husband of the same. Their outfit to be determined and supplied by the administrative authority under this Act.

An obstetric nurse under this Act must have at least three months' training in a recognised metropolitan or provincial lying-in hospital, and be examined theoretically by written papers and practically at the bedside, and must show herself competent to act in cases of emergency, such as in sudden labour, alarming hæmorrhage, and threatened death of the mother or child until the doctor engaged to attend arrive, or, in the event of his absence, until the arrival of a properly qualified and registered substitute. In addition to a practical knowledge of modern antiseptic midwifery and the general management of lying-in women and newly-born infants she must have a practical acquaintance of domestic duties and be able to do plain cooking for her patient and, if necessary, for her husband and family, and she must be prepared to do the necessary washing for mother and child in cases of extreme poverty, and she must be provided with a change of linen and undergarments for both mother and child, whether they may be required or not, and in no case shall she accept fees, gratuities, or remuneration from the patient, or her husband, or any relative or friend. For salary of obstetric nurses see schedule to Clause 5. Obstetric nurses must be neatly and cleanly dressed, but need not necessarily wear costume, and their outfit must in all cases be supplied and determined by the administrative authority under this Act. And the travelling expenses of both sick and obstetric nurses beyond a mile from their residence (which must be central) are in all cases to be defrayed, and in accordance with a scale to be fixed, by the administrative authority. And in addition to the direct and immediate supervision by the members of the medical staff there must be a general supervision of the nurses by the secretaries of those authorities, who shall report neglect of duty and delinquencies to their governing authority.

*Schedule D. Clause 5. Sub-clauses b and c.*—Practical illustration of the income and expenditure of a voluntary nursing association employing a sick and obstetric nurse in a parish of 7000 inhabitants, with three resident doctors. Take average births at 180, and for comparative purposes divide these into three sixties, as follows:—

1st 60,	wages 30s. to 40s. per week,	to contribute 15s.
2nd 60,	" 20s. to 30s. "	" 10s.
3rd 60,	" 20s. and under "	" 5s.

An honorarium of 5s. to be added to each of the above contributions, making doctor's fees 20s., 15s., and 10s. respectively, or an average of 15s. each.

#### CASH ACCOUNT.

Dr.	£	Dr.	£
Income from woman's contributions ... ..	90	Doctor's fees ... ..	135
Subscriptions, donations, &c. ... ..	180	Sick nurse ... ..	60
		Obstetric nurse ... ..	60
		Incidentals ... ..	15
Total ... ..	£270	Total ... ..	£270

A "grant in aid" under this Act of £25 to the above credit account would enable a voluntary association adopting this Act to employ a "second grade" sick nurse, and of £50 a "first grade" sick nurse. In order to encourage the adoption of this Act by the authorities named therein, and especially to encourage and facilitate the establishment of voluntary nursing associations, "grants in aid" to be made conditional on the subscriptions and donations and the women's contributions attaining a fixed standard, which might be two-thirds at least of the required income, based on the birth-rate and financial capabilities of the parish or district. The medical fees scheduled herein are to be exclusive of mileage as provided for in clause 8.

*Schedule E to Clause 9.*—The rules regulating the conduct and duties of sick and obstetric nurses shall be drawn up by a committee of the adopting authority or voluntary association, and no rule shall be made in the absence of the members of the medical staff, and if no member of the medical staff be present, the committee must adjourn, and due notice be given to each member of committee, including the medical members, so that all or as many as possible may be present at the adjourned meeting. And the rules and regulations shall conform so far as possible to the local circumstances of the parish or district, and if any dispute arise in reference to the adoption of any proposed rule or regulation, and if any nurse or member of the medical staff feel aggrieved by the action of the managing committee, or by their rules and regulations, he or she may summon a general meeting of the subscribers by giving seven days' notice to the secretary, who must thereupon issue notices for the meeting to be held at the earliest possible date, and the decision of the meeting shall be final, always provided that in matters affecting the professional conduct of the medical staff, or any member of it, the appeal must be to the General Medical Council.

## ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

THE annual election meeting of the College was held on Dec. 6th, 1901, when the following office-bearers were elected for the ensuing year:—President: Dr. T. R. Fraser. Vice-President: Dr. J. Andrew. Council: the President, the Vice-President, Dr. John Wyllie, Sir John Batty Tuke, Dr. T. S. Clouston, Dr. G. A. Gibson, and Dr. D. Berry Hart.—An extraordinary meeting of the College was held on Dec. 17th, Dr. Fraser, the President, being in the chair: The secretary reported that the following office-bearers had been elected by the Council for the ensuing year:—Treasurer: Dr. Peter A. Young. Secretary: Dr. R. W. Philip. Librarian: Dr. George W. Balfour. Curator of research laboratory: Sir John Batty

Tuke. A report was submitted by Dr. Graham Brown to the effect that he had the honour of presenting in person to Professor Virchow on his eightieth birthday the address of the College and that Professor Virchow, in thanking the College, had paid a pleasing compliment to the College and its laboratory. The College unanimously re-appointed Dr. Andrew and Dr. Young to be its representatives on the Board of Management of the Royal Infirmary.

## THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeon C. Pearson to the *Grafton*. Surgeons: E. G. E. O'Leary and J. Stoddart to the *Grafton*.

### ROYAL ARMY MEDICAL CORPS.

Major James McM. Bolster retires on retired pay. Dated Dec. 21st, 1901.

### ARMY MEDICAL RESERVE OF OFFICERS.

The undermentioned officers having resigned their commissions in the Volunteer Forces cease to belong to the Army Medical Reserve of Officers: Surgeon-Major S. H. Moore and Surgeon-Captain C. E. R. Bucknill.

### MILITIA MEDICAL STAFF CORPS.

Surgeon-Lieutenant J. Davies to be Surgeon-Captain.

### IMPERIAL YEOMANRY.

Sussex: Edward Stewart, late Surgeon Middlesex Imperial Yeomanry, to be Surgeon-Captain.

### VOLUNTEER CORPS.

*Artillery:* 2nd Kent: Surgeon-Lieutenant-Colonel R. Gooding resigns his commission, with permission to retain his rank and to wear the uniform of the corps on retirement. 2nd Sussex: Harry Edward Hewitt to be Surgeon-Lieutenant. *Electrical Engineers:* Cecil Huntington Leaf to be Surgeon-Lieutenant. *Rifle:* 4th Volunteer Battalion the King's (Liverpool Regiment): Brigade-Surgeon-Lieutenant-Colonel W. J. Fleetwood resigns his commission, with permission to retain his rank and to wear the uniform of the battalion on retirement, vacating at the same time his appointment as Senior Medical Officer to the Mersey Volunteer Infantry Brigade. 3rd (Dumfries) Volunteer Battalion the King's Own Scottish Borderers: Surgeon-Major W. D'O. Grange resigns his commission, with permission to retain his rank and to wear the uniform of the battalion on retirement. 1st (Oxford University) Volunteer Battalion the Oxfordshire Light Infantry: Surgeon-Lieutenant W. T. Brooks to be Surgeon-Captain. 2nd Volunteer Battalion the Sherwood Foresters (Derbyshire Regiment): Herbert Shipton to be Surgeon-Lieutenant.

### VOLUNTEER MEDICAL STAFF CORPS.

The Manchester Companies: Walter Reginald Norman Smithard to be Surgeon-Lieutenant; Claude William Scott Saberton to be Surgeon-Lieutenant. The Woolwich Companies: Surgeon-Lieutenant M. Taylor is borne as Supernumerary whilst serving with the Royal Army Medical Corps in South Africa.

### SOUTH AFRICAN WAR NOTES.

Lieutenant-Colonel T. P. Woodhouse, R.A.M.C., and Civil Surgeons Cleary, Dickson, Ritchie, and Keenan are on passage home.

### THE VOLUNTEER AMBULANCE SCHOOL OF INSTRUCTION.

At the headquarters of the Artists Rifle Volunteers, Duke-street, Euston-road, on Dec. 11th, Colonel Sir Thomas Gallwey, K.C.M.G., C.B., R.A.M.C., principal medical officer of the Home District, inspected the present classes of the Volunteer Ambulance School of Instruction and distributed the prizes. Among the other officers present were Brigade-Surgeon-Lieutenant-Colonel P. B. Giles, V.D., senior medical officer of the school; Major Maclure, late of the London Scottish Volunteers, president of the school; and Major W. H. P. Lewis, and Lieutenant L. F. Forbes Winslow, R.A.M.C. examiners; Surgeon-Major R. R. Sleman, late C.I.V., and Surgeon-Lieutenant Hudson and Surgeon-Lieutenant R. Roche. Any efficient member of the Yeomanry or Volunteers may join the school and receive instruction. In the advanced class the best team

proved to be four members of the 1st Cadet Battalion of the King's Royal Rifles, while the best man was Private P. H. Freeman of the same battalion. In the new class a team of the 1st Cadet Battalion, King's Royal Rifles, also took first place, winning the Hamilton Challenge Bowl, a team of the 3rd Volunteer Battalion the Queen's being second. Private G. L. Paxton of the London Rifle Brigade and Private F. Couling, 21st Middlesex Rifle Volunteers, obtained prizes for individual good work. The victory of the cadets is all the more creditable to them as they have to meet in competition some of the best corps of the Home District, including the Honourable Artillery Company, the London Rifle Brigade, the London Scottish, the Artists, the 2nd Volunteer Battalion Royal Fusiliers, and the Queen's Westminster Volunteers. Colonel Gallwey, addressing the class after inspection, said that in the war now waging in South Africa perhaps no branch of the army wanted aid more than the medical branch did. By assisting the sick and wounded they were doing as much as any other soldiers in the field. He had taken part in the war and could speak in high terms of the service which the medical branch had rendered to the sick and wounded. At the conclusion of Colonel Gallwey's address a considerable number of the men stepped forward and volunteered for active service in South Africa with the Royal Army Medical Corps. Up to the present time Brigade-Surgeon Giles has sent over 100 non-commissioned officers and men for duty with the corps, a considerable portion of whom are still serving abroad. The next class for the training of regimental stretcher-bearers will be held at the London Scottish headquarters, James-street, and will commence early in February.

#### LIGHT RAILWAY AMBULANCES IN WEST AFRICA.

The Liverpool Chamber of Commerce has sent to the Secretary of State for the Colonies, Mr. Chamberlain, a design with drawings for a corridor train for the British West African railway services by Lieutenant-Colonel J. J. Lamprey, I.M.S. The carriage has accommodation for 30 persons, 12 lying down, 12 seated, and six attendants. It can be utilised at a junction or at a siding as a temporary field hospital as it will be complete in every equipment—drugs, instruments, and dressings, a kitchen, with a store-room and a medical-comfort box, water-tank, larder, and pantry. Lieutenant-Colonel Lamprey claims that his car will not only do for a corridor train, but will act as a general purpose saloon for railway service on the West Coast of Africa. Wire-wove seats and cots will add greatly to the comfort of invalids and travellers. At present the sick and wounded are placed on stretchers resting across the backs of the seats in open railway carriages—a practice which, apart from the agony of jolting and the discomfort to the patient, is primitive and not without danger to the health of the traveller. All who may have recently returned from visiting Lagos, the Gold Coast, and Sierra Leone are of opinion that light railway accommodation should be made as convenient and as comfortable for West African railway services as they are in India or other tropical countries, especially for invalids.

#### ST. JOHN AMBULANCE BRIGADE AND RECRUITING.

The Inspector-General of Recruiting has issued the following circular memorandum to general officers commanding districts:—"Many instances having recently been brought to notice in which men of the St. John Ambulance Brigade and others applying for enlistment in the Royal Army Medical Corps for service during the war in South Africa, under Army Orders 86 and 159 of 1901, have not found every facility afforded them by the recruiting authorities, the attention of officers commanding recruiting areas is drawn to the fact. Every step possible should be taken to facilitate the enlistment of such men, as the greatest difficulty is experienced in providing for the continual drafts of the Royal Army Medical Corps requisitioned for service in South Africa."

The Imperial Yeomanry Hospitals Committee has decided to support the scheme proposed by Major-General Eaton and approved by Lord Pirbright of utilising the Bisley Homes for children of soldiers who have died in the war in South Africa. The surplus Yeomanry Hospital Funds will be accordingly devoted to the maintenance of one of the homes, accommodating 16 children, for the orphans of Imperial Yeomanry men.

## Correspondence.

"Audi alteram partem."

### THE PERSONAL FACTOR IN TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—The profession owes you a debt of gratitude for reproducing, in THE LANCET of Nov. 9th. p. 1250, the address by Sir Dyce Duckworth on "The Personal Factor in Tuberculosis." In strong contrast to the special pleading with which the advance guard of the National Association for the Prevention of Consumption and Other Forms of Tuberculosis has made us familiar, we have here the calm, judicial summing up of the case in the interests of truth, the whole truth, and nothing but the truth.

Sirs, we are living in critical times. The present attitude of some of the accepted leaders of our profession compels the conclusion that the royal patronage of science is little less than a national misfortune, if not a world calamity. It may be that the heading up of so-called "popular" movements and the stump oratory by means of which the dissemination of their propaganda is brought about, can be justified to some conceptions of the ethical code, but nothing can justify the absurd pretensions that are being put forward as to the extraordinary, if not miraculous, cures which result from "treatment" in sanatoriums. The fact that the "cured" of certain belauded places are dying on all hands, and the knowledge that over the door of the sanatorium is written, "Abandon hope, all ye that enter here," to patients with physical signs, does not appear to damp the ardour of these enthusiasts. There has, however, been a considerable climb down recently. Instead of the conversion, within the space of three months, of people with "crushed-in chest walls" into "great broad-shouldered men" we are now informed that the chance of complete cure is almost confined to first-stage cases—a new definition of first-stage having been evolved from the exigencies of the situation. At the International Congress this stage was defined as "a man takes cold (*sic*) and has a cough, which is neglected"—sufficiently elastic, it will be granted, to ensure the success of any institution of the kind and to make visitors inquire "Where are your patients?" as well as to afford a reasonable explanation as to how it comes to pass that so many of the "cured" are engaged at the present time in beating the tom-tom of the sanatorium. Now I should like to ask three questions: 1. Is any scheme devisable by means of which the aspirations of the National Association can be attained? 2. Judged by their own theories of disease causation, does the aggregation of cases of consumption in sanatoriums recommend itself to ordinary common-sense? 3. Are these extraordinary efforts being directed in the true spirit of disease prevention?

Dealing with the first question, let me point out that for the 10 years 1881-90 the average number of deaths each year from consumption in England and Wales was 66,526; of these, 43,832 were those of persons between the ages of 15 and 65 years—the wage-earning period of life. Now let us take a glance at the length of time which is considered necessary for a so-called cure. Mr. Braine-Hartnell of the Cotswold Sanatorium says: "If a patient has no physical signs, no temperature, no cough or expectoration, and *if he keeps up this condition for two or three years*, then and then only can he be called cured." Again, "The man who can live in a sanatorium for 12 months and then spend the rest of his life as a country gentleman must necessarily stand a better chance," &c. Dr. Clifford Allbutt tells us that "to bring about obsolescence in phthisis, even of the first stage, we need, in my opinion, two winters and one summer at least, and in saying this I am astonished at my own moderation. In many cases three winters and two summers will be needed"; and he adds some words which invalidate all his arguments in favour of sanatorial treatment when he concludes: "But how many, even in the easier classes, can sacrifice this time without breaking up their careers and abandoning their ties of home?"

It becomes perfectly evident, then, that should the Government or the municipalities of this country ever make the effort to carry the sanatorium treatment to its legitimate conclusion the very earliest discovery that would be made

would be that the financial problem alone was absolutely insoluble.

Does the aggregation of cases of consumption recommend itself to ordinary common sense? We have been taught that consumption is an infective disease. If this theory of infectivity be not the invention of public-health enthusiasts brought out for the purpose of panic-striking the world into the acquiescence in compulsory notification and compulsory isolation—if it can be regarded as a sober, workable theory that may be expected to stand the strain of reasonable tests, can it be contended that the best way to treat phthisical patients is to secure their constant exposure to the very organism which forms the *causa vera* of their trouble? The aggregation of the infective sick is bad at all times and under all conditions. It has been shown that phthisical patients during the acts of coughing and speaking fill the air not only in front but laterally and behind with tubercle bacilli. Is it really contended that a line of treatment which insists on the exposure of one's patient to this bacillus-contaminated atmosphere, that compels association with others who are compassed about with what Professor Koch describes as the *circulus vitiosus*, that ensures the constant inhalation and ingestion of the very organism which forms the *causa causans* of their disease, has any rag of scientific sanction? Outside the walls of the sanatorium healthy people are taught that a barbarous ostracism of their kith and kin is only a justifiable measure of precaution, and are we to understand that the patient of the sanatorium who is in the "first stage" of the disease and who may have anything or nothing the matter with him and the man in whom "hereditary predisposition" has prepared the soil for the reception of the tubercle bacillus are in any less danger than healthy people outside?

In THE LANCET of Nov. 30th, p. 1515, Dr. Louis C. Parkes argues that the principle involved in the isolation and treatment of consumptives in sanatoriums is the same as that involved in the isolation and treatment of scarlet fever and diphtheria and as a measure to safeguard the public. What have been the fruits of aggregation in these diseases? Secondary infection and the creation of a mixed infections disease more deadly than either scarlet fever or diphtheria—namely, post-scarlatinal diphtheria. As to the protection of the public, if the creation of endemic fever can be so designated, the public is well protected indeed. Keeping in mind the length of detention in sanatoriums for consumptives nothing is more certain than this—that if secondary infection does not take place there is something desperately wrong with the infection theory, which is extremely probable. Public health enthusiasts have worked this theory for all it was worth and a little more, indulging the vain hope that this long route to disease prevention would be taken by the governments and municipalities of the civilised world. From London to York the distance, as the crow flies, is 200 miles or 24,000 miles—it all depends on the direction you take. The "scientists" of the present day prefer the longer route.

This brings us to a consideration of the third question: "Are these extraordinary efforts being directed in the true spirit of disease prevention?" The answer to this question may be sought in the experience of the past. In the days when science was the systematisation of knowledge and not a guessing competition under the patronage of emperors and kings a mighty work had been accomplished in these lands. The death-rate from consumption had been diminished by 50 per cent. How had these great results been achieved? They had been brought about, not by notification, isolation, inspection, and compulsion, but by works of sanitation carried out on common-sense lines. Herein are the ways and means of preventing disease, which are several times more advantageous to the community than curing it even if this could be accomplished.

What are the causes of consumption? The two chief causes are want of cubic space and defective drainage. Of course, this is rank heresy; but let it pass. What happens when so-called infected areas are drained and cubic space is increased? Let us see. Hueppe—who of all modern scientists is less severely bitten by the modern craze to make the individual the scapegoat to bear the sins of us all—says clearly that we must look to drainage and to works of sanitation generally for the accomplishment of the ends we have in view. Dr. Buchanan showed that great diminution in the deaths from phthisis followed the laying of main drains in the following towns, among others: Salisbury (49 per cent. of its previous rate),

Cheltenham (26 per cent.), and Bristol (12 per cent.). Dr. W. H. Symons, medical officer of health of the city of Bath, declares that "the consumption death-rate may be a measure of the sanitary condition of the town or district." Dr. Arthur Ransome points out that "the death-rate from consumption amongst the English troops quartered in Canada was 23 per 1000, against 10 per 1000 of their compatriots stationed at home. After the barrack had been properly drained and ventilated the mortality had sunk from 23 per 1000 in 1865 to 9.5 in 1872 and 6 in 1874." Again, Dr. Guy's investigations led him to the conclusion that the cause of the disease was insufficient cubic space. "Of 104 men having less than 500 cubic feet of air, 13 suffered from blood-spitting and 13 from catarrh. Of 115 who had 500 feet to 600 feet five suffered from the former and four from the latter. Of 101 men having more than 600 feet only four suffered from blood-spitting and two from catarrh." Once more Dr. Parkes relates how in the badly-ventilated prison, the Leopoldstadt of Vienna, the death-rate from consumption was, 1834-1847, 51.4 per 1000, while in the well-ventilated House of Correction in the same city only 7.9 per 1000 died from phthisis.

It is quite clear, then, that we must look to works of sanitation and not to sanatoriums for the accomplishment of the ends we have in view. The sanitary engineer, working slowly yet surely, must displace the medical enthusiast who, with a light heart, is prepared to advise the incurring of another national debt for the purpose of covering the country with his so-called cure-houses.

Against the determination to add consumption to the long list of specialised subjects I enter an earnest protest. Dr. Clifford Allbutt declares that he looks "with little confidence to the treatment of phthisical patients by a physician unused to the practice of the sanatorium." Again, "It is not too readily to be admitted that the treatment can be carried out elsewhere than in a sanatorium." If this is not a claim that a "corner" has been established in fresh air—which commodity "cannot be obtained at any other house in the trade"—it is nothing. The contention of Sir Dyce Duckworth that there is a danger that the personal factor may be ignored and that the disease and not the patients will be treated "like so many ninepins turned off the same lathe out of one block of wood" is met by a declaration of Dr. Clifford Allbutt that "it is no paradox to say that in the congregations of the sanatorium we have learnt individual treatment." What! with one physician to 50, 60, or 70 patients? I say that it is a very considerable paradox. I say that "the thralldom of routine and the grosser temptations of the hotel-keeper" are set dead against individual treatment. The suggestion of Dr. Parkes that sanatoriums should be established "as safeguards to the public health" means nothing less than that they should be used as prisons in which consumptives shall be compulsorily detained. That this is the aim and object of many public health officials we have been made aware, but that Englishmen will ever consent to take such a toll of humanity is not believable.

I am, Sirs, yours faithfully,

Nottingham, Dec. 10th, 1901. EDWARD DEAN MARRIOTT.

## EXCESS OF SALT IN THE DIET A PROBABLE FACTOR IN THE CAUSATION OF CANCER.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Dec. 7th I read with great interest Dr. Braithwaite's article on the Causation of Cancer. In a semi-popular book entitled, "Fads of an Old Physician," Dr. George Keith gives expression to a theory which is practically the same as Dr. Braithwaite's, though he endeavours to substantiate it more from the therapeutic point of view. In Chapter vii. of this book Dr. Keith says: "I had long known that high living, that is, the use of wine and other stimulants, and of strong animal food, aggravated in an extraordinary manner all the symptoms arising from this terrible disease." I am sure that the whole chapter will prove of interest in connexion with Dr. Braithwaite's theory.

I am, Sirs, yours faithfully,

H. CRICHTON MILLER, M.B. Edin.

San Remo, Italy, Dec. 15th, 1901.

## NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

*The Plague Epidemic.—Commissions to Plague Medical Officers.—The Soldier's Beer.—The Water-supply of Rangoon.—Interesting Points in the Treatment of Rabies.*

ALTHOUGH the virulence of the plague epidemic seems to be abating in the worst districts of the Bombay Presidency the disease is spreading and developing in other parts. For the week ending Nov. 23rd there were 8431 deaths from plague throughout India, as compared with 8710 deaths for the previous seven days. The decrease in the Bombay Presidency was from 6859 to 5980 and in Bengal there was a reduction in the number of deaths from 258 to 173. On the other hand, the Punjab returned 1220 deaths as against 851, and the Lahore district has for the first time become infected. The Mysore State reported 447 deaths as compared with 416 during the previous week. The most serious development has occurred at Poona. The whole place has now become infected and large numbers of rats have been found dead and dying in several quarters. This recrudescence at Poona was foreshadowed several weeks ago, but the people there imagined that they were going to escape and the outbreak is described as a hidden rising. A meeting has only recently been held to concert plans for abating it. Had the authorities studied the history of outbreaks they would have known what to expect. In Calcutta there are already signs that another outbreak may be expected. There have only been a few more deaths from plague reported, but the total mortality, which has for some time been below normal, has steadily increased. It may be several weeks before the recrudescence distinctly shows itself, but that it will come there can be little doubt. In Bombay the weekly return of deaths from plague continues at about 170 or 180—the rate of general mortality being about 52 per 1000. In Madras there is also a very high death-rate, the last return giving it at 60·5 per 1000 as compared with the average of 39 per 1000, but the deaths here are chiefly due to cholera, bowel complaints, and "fever."

The Secretary of State has decided to offer 22 commissions in the Indian Medical Service to the medical men who were engaged to combat the plague. Those who accept will be ranked under the forthcoming batch of candidates from Netley. Only those who were within the prescribed age when they commenced plague duty will be selected. For the junior men this may be an advantageous offer, but even for them it would be better to go home and to compete in the usual way. Those who accept the proffered commissions will always be "marked" men, and it is doubtful whether they will ever get the same standing as their regular colleagues.

Following the scare of poisoned beer in Lancashire it has been ruled by the military authorities in India that all beer issued to troops, whether country-brewed or imported, shall be periodically subjected to chemical analysis under arrangements to be made by the sanitary officer of the command.

Rangoon has for some time past been troubled about its water-supply. Experiments have been made ever since 1894 to find out whether tube wells would solve the difficulty. In a recent report by the sanitary engineer it was shown that the wells which have been made are altogether unsatisfactory and that the cost of increasing them would be prohibitive. Moreover, the supply and nature of the water cannot be depended upon. The conclusion come to is that tube wells in Rangoon are only suited for mills and factories. The waterworks scheme which I have previously reported upon will therefore probably be proceeded with.

The returns of the Pasteur Institute at Kauli are of more than passing interest. During the past year the failures in treatment have been only 1 per cent. and no failures occurred among the European patients. The extraordinary virulence of the poison from the fangs of a mad jackal are not sufficiently recognised. Forty natives were bitten by one jackal, of whom six died, but in three of the deceased the disease set in within 14 days of the completion of treatment. Natives delay in attending for treatment. The usual incubation period when the virus is implanted on a rabbit's brain is 14 days. It has been made clear that special measures are necessary when the jackal's virus has to be dealt with and the usual course must be accelerated. The mortality from bites of mad jackals averages 85 per cent. where no treatment is given. Since this batch of 40 cases there have been 15 cases of jackal bite treated by a more intensive method

and not a single failure has been reported. In connexion with the Pasteur treatment for rabies it is interesting to note the custom of centuries ago in Egypt. The people then took out the rabid animal's brain and spinal cord which they rubbed thoroughly, like oil, into the skin of the patient. How often this was done I have not seen recorded, but it is quite possible that through abrasions in the skin, perhaps through the wound itself, the virus was introduced and immunised the patient against the usual subsequent development of the poison.

Nov. 29th.

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

*The Liverpool University Scheme.*

At a meeting of the Liverpool University Committee held on Dec. 17th Principal A. W. W. Dale, of University College, being in the chair, the executive committee presented their report, in which they recommended that efforts be made to raise an additional capital sum of £330,000 and a further income of £9000 a year. Of the above capital sum, which it is hoped may be provided by the gifts of Liverpool citizens and others interested in higher education, £130,000 would be required for the erection and equipment of additional buildings and for the purchase of more land. The balance of £200,000 would supply an endowment for the professional chairs and lectureships most urgently needed and the organisation of a department for commercial education in its highest branches. The report will in due time be submitted to the council of University College, and in the event of approval the Lord Mayor will be asked to convene a town's meeting to consider the subject of founding a university for the city of Liverpool.

*Presentation to Dr. T. R. Glynn.*

In the early part of the year Dr. T. R. Glynn's colleagues at the Royal Infirmary and other medical friends, on the occasion of his retirement from the office of honorary physician to the Royal Infirmary, determined to mark their appreciation of his long and devoted services to that charity by presenting him with his portrait painted in oils. The picture, which was painted by Mr. R. E. Morrison, a well-known local artist, is now in the Liverpool autumn exhibition, where it has been universally admired as a most striking likeness. The surplus amount of the subscriptions collected for the purpose was utilised in adding the portrait of Mrs. Glynn to that of her husband. On Dec. 18th the portraits were presented to the esteemed couple at a dinner given by the subscribers to the testimonial. The gathering, which took place at the Adelphi Hotel, was a large and representative one and was graced by the presence of ladies. After the usual loyal toasts had been honoured Dr. Richard Caton, the chairman, proposed "The Guest of the Evening" in cordial terms. He referred to Dr. Glynn's long services to the Royal Infirmary and the immense value of his work as a physician and teacher of medicine, and told him how much he was missed by the patients, the students, and his late colleagues at the Royal Infirmary. On behalf of the subscribers he begged Dr. and Mrs. Glynn to accept the portraits. Dr. Glynn made a suitable reply, which was received with enthusiasm. Mr. Rushton Parker proposed Mrs. Glynn's health in a humorous speech which caused much merriment, and to the delight of everyone present Mrs. Glynn made a happy response on her own behalf. Sir William Banks paid a high tribute to Mr. R. E. Morrison's skill and success as a portrait painter, remarks which were suitably acknowledged by Mr. Morrison.

Dec. 22nd.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

*A Medical Divorce.*

ANOTHER medical drama, played out, however, in the law-courts and not on the stage, has just been presented to the public. A medical man sued for a divorce against his wife, and the wife, in order to get some counter-evidence against her husband, employed a detective agency to watch and to report to her. She even laid a trap for him as follows. She suborned a woman to consult him, and this woman asked him to come to her house. When he arrived there he in

the course of his examination proceeded to auscultate her chest, and at the moment when he was listening to her heart from behind, with his ear close against her back, a whole troop of persons burst into the room—including his wife, her father and her mother—who all screamed in concert and declared that the auscultation was nothing but a pretence. The persecuted physician has accordingly sued everyone concerned, including the detective agency, for 100,000 francs damages.

Dec. 23rd.

## Medical News.

UNIVERSITY OF LONDON.—The following candidates have been successful in the examinations indicated:—

### M.S. EXAMINATION.

Joseph Faulkner Dobson, Yorkshire College and General Infirmary, Leeds; Arthur Henry Evans, Westminster Hospital; Hugh Mallinson Rigby, London Hospital; and Philip Turner, Guy's Hospital.

### M.D. EXAMINATION.

**Medicine.**—Frederick Holgate Atkinson, Charing-cross Hospital; Arthur Stanley Barnes, B.Sc., Birmingham University; Edward Vipont Brown, St. Bartholomew's Hospital and Owens College; Stanley Arthur Bull, Westminster Hospital; Joseph E. Goodfellow Calverley, B.Sc., St. Bartholomew's Hospital; Harold Selwyn Capper, University College; Arthur Stanbury Cobbedick, B.Sc., St. Bartholomew's Hospital and Bristol Medical School; Maurice Were Coleman, St. Bartholomew's Hospital; Albert Ruskin Cook, B.Sc., St. Bartholomew's Hospital and Cambridge University; Percy Robert Cooper, B.Sc., Owens College, Manchester Royal Infirmary, and St. Bartholomew's Hospital; Frank Sherwill Dawe, B.Sc., St. Mary's Hospital; John Thomas Dunston, B.Sc., Herbert Lightfoot Eason, B.Sc., and William Norwood East, Guy's Hospital; Joseph George Emanuel, B.Sc., B.Sc., Birmingham University; William Layard Griffiths, B.Sc., University College; John Grimshaw, London Hospital; George Henry James Hooper, Charing Cross Hospital; Charlotte Elizabeth Hull, B.Sc., and Mary Muriel Griffin Iles, B.Sc., London (Royal Free Hospital) School of Medicine for Women; Frank Harwood Jacob, King's College; Harriett Minnie Levick, B.Sc., London (Royal Free Hospital) School of Medicine for Women; Donald Johnstone McGavin, Queen's Hospital, Birmingham, and Birmingham University; Brian Melland, Owens College and Manchester Royal Infirmary; Julius Moore, Guy's Hospital; Winifred S. Patch, B.Sc., B.Sc., London (Royal Free Hospital) School of Medicine for Women; Arthur Robert George Pocock, University College; George E. J. A. Robinson, B.Sc., King's College and Dublin University; \*Lewis Albert Smith, London Hospital; Mabel Geraldine Stevenson, B.Sc., London (Royal Free Hospital) School of Medicine for Women; Walter Henry Maxwell Telling, B.Sc. (Gold Medal), Guy's Hospital and Leeds General Infirmary; Harold John Van Praagh, St. Mary's Hospital; Ethel Miller Vernon, B.Sc., London (Royal Free Hospital) School of Medicine for Women; William Bertram Watson, St. Mary's Hospital; Eliza Turner Watts, B.Sc., London (Royal Free Hospital) School of Medicine for Women; and William Henry Willecox, B.Sc., St. Mary's Hospital.

**State Medicine.**—Francis Seymour Lloyd, St. Mary's and Guy's Hospitals.

\* Obtained the number of marks qualifying for the Gold Medal.  
N.B.—The foregoing lists, published for the convenience of candidates, are provisional only, and are not final until the reports of the Examiners shall have been confirmed by the Senate.

UNIVERSITY OF CAMBRIDGE.—At the third examination for medical and surgical degrees, Michaelmas term, the following candidates were successful:—

### PART II.

**Medicine.**—R. G. Abercrombie, B.A., Caius; A. G. Bate, King's; F. H. Beckett, B.A., H. Selwyn; A. P. Bowdler, B.A., Sidney Sussex; F. G. Bowen, B.A., Caius; C. de L. Carey, B.A., Emmanuel; E. I. Claxton, B.A., King's; J. G. Cooke, B.A., Sidney Sussex; G. W. Deeping, B.A., Trinity; A. B. Dunn, B.A., Queen's; A. J. Fairlie Clarke, B.A., Emmanuel; A. C. Hudson, B.A., Trinity; E. B. Leech, B.A., Christ's; D. J. Morgan, B.A., and J. S. S. Perkins, B.A., St. John's; J. W. Pettinger, B.A., H. Selwyn; H. V. Pryce, B.A., and J. W. Rob, B.A., St. John's; R. Rolfe, B.A., Clare; F. Sanger, M.A., St. John's; A. de W. Snowden, M.A., Christ's; J. Stirling-Hamilton, B.A., Jesus; E. J. D. Taylor, B.A., Caius; G. L. Tuck, B.A., Emmanuel; E. G. Wales, B.A., Downing; H. H. Weir, B.A., Trinity; J. Wharton, B.A., St. John's; M. Wilson, B.A., Trinity Hall; and F. E. Wood, B.A., Downing.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held in December the following candidates passed in the subjects indicated:—

**Surgery.**—J. W. W. Adamson (Section I.), St. George's Hospital; A. A. E. Baptist, Calcutta; R. O. Bennett, University College Hospital; L. Courtauld (Section I.), Cambridge and Middlesex Hospital; W. P. A. Hardwicke, Durham; D. V. Muller (Section II.), Charing Cross Hospital; F. A. Paterson (Section II.), Royal Free Hospital; W. G. Rogers (Sections I. and II.), Cardiff and Charing Cross Hospital; C. W. Smith (Sections I. and II.), Sheffield; W. Thorp (Sections I. and II.), Royal Free Hospital; and C. Watson (Sections I. and II.), Dublin and Westminster Hospital.

**Medicine.**—W. Alcock (Sections I. and II.), Sheffield; T. J. M. Clapperton (Sections I. and II.), King's College Hospital; J. T. Crowe, St. Mary's Hospital; J. M. King (Sections I. and II.), University College Hospital; C. A. Lower (Section II.), Guy's Hospital and Bristol; D. V. Muller (Section II.), Charing Cross

Hospital; W. G. Rogers (Sections I. and II.), Cardiff and Charing Cross Hospital; C. W. Smith (Sections I. and II.), Sheffield; W. Thorp (Sections I. and II.), Royal Free Hospital; S. C. Wilkinson (Sections I. and II.), Leeds; and J. H. Williams London Hospital.

**Forensic Medicine.**—T. J. M. Clapperton, King's College Hospital; W. T. Colyer, Cambridge; G. Cross, St. Thomas's Hospital; J. T. Crowe, St. Mary's Hospital; W. G. Rogers, Cardiff and Charing Cross Hospital; C. W. Smith, Sheffield; and W. Thorp, Royal Free Hospital.

**Midwifery.**—J. H. Clements, University College Hospital; K. A. Dawson, Royal Free Hospital; A. Dewar, McGill and Westminster Hospital; G. Dewick and B. M. Dunstan, St. Thomas's Hospital; H. J. Gater, D. R. T. Griffiths, and G. W. C. Hollist, Guy's Hospital; A. Holroyde, Leeds; C. H. Pring, Westminster Hospital; W. G. Rogers, Cardiff and Charing Cross Hospital; C. J. Taylor, Bristol; and W. Thorp, Royal Free Hospital.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: J. T. Bennett, T. J. M. Clapperton, G. Cross, J. T. Crowe, C. A. Lower, D. V. Muller, F. A. Paterson, W. G. Rogers, C. W. Smith, and W. Thorp.

### FOREIGN UNIVERSITY INTELLIGENCE.—Graz:

Dr. O. Drasch has been promoted to a full Professorship of Histology and Embryology.—*Königsberg*: Dr. Scholtz has been recognised as *privat-docent* of Dermatology.—*Marsailles*: Dr. Boinet has been appointed Clinical Professor of Medicine.—*Rio de Janeiro*: Dr. Miguel Couto has been recognised as *privat-docent* of Surgical Anatomy.—*Rome*: Dr. Ambrogio Cuneo has been recognised as *privat-docent* of Surgical Anatomy and Operative Medicine.—*Strasbourg*: Dr. Karl Adrian has been recognised as *privat-docent* of Dermatology.—*Vienna*: Dr. Heinrich Albrecht has been appointed Extraordinary Professor of Pathological Anatomy.

**SUPERANNUATION.**—At the meeting of the Exeter Board of Guardians held on Dec. 17th Dr. John Woodman, who has recently resigned the post of medical officer to the city workhouse after 35 years' service, was granted a superannuation allowance of £64 per annum. A motion of appreciation of the services of Dr. Woodman was unanimously passed.

**ROYAL UNITED HOSPITAL, BATH.**—At the meeting of the committee of this hospital held on Dec. 16th it was stated that Mr. Richard J. H. Scott and Mr. Frederick K. Green, senior surgeons to the institution, had resigned their appointments. The resignations were accepted with great regret, both gentlemen having been connected with the Royal United Hospital for over 20 years.

**THE LATE PROFESSOR ALFRED HUGHES.**—The committee appointed in connexion with the proposed memorial to the late Professor Alfred Hughes have collected the sum of £1800, inclusive of £1000 given by Mrs. Hughes. This amount is to be handed over to the Cardiff College Council to provide an "Alfred Hughes Memorial Medal" to be awarded annually in the class of anatomy at the college and also to endow the anatomical museum of the college.

**FREEMASONRY.**—*Cheselden Lodge, No. 2870.*—At a meeting of this lodge held at the Trocadero, Piccadilly-circus, on Monday, Dec. 16th, the W.M. Bro. Thomas Wakley, jun., being in the chair, Mr. J. G. Wainwright, Treasurer of St. Thomas's Hospital; Mr. C. A. Ballance, M.S. Lond., F.R.C.S.; the Rev. Gilbert Weigall, Chaplain of St. Thomas's Hospital; Mr. F. C. Abbott, M.S. Lond., F.R.C.S.; and Mr. H. C. Jonas, M.R.C.S., L.R.C.P. Lond., were initiated into Freemasonry.

**GREAT ORMOND-STREET HOSPITAL FOR CHILDREN.**—On Jan. 15th, 1902, a grand children's fancy-dress ball will be held in the concert-room of the Crystal Palace in aid of the Great Ormond-street Hospital for Children. Among the patrons of the ball are the Duchess of Teck, the Duchess of Newcastle, the Marchioness of Londonderry, the Marchioness of Waterford, the Countess of Bradford, the Countess of Essex, the Countess of Lonsdale, the Countess of Pembroke, the Countess of Warwick, Lady Brassey, and Lady Howard of Glossop.

**BACTERIOLOGICAL EXAMINATIONS.**—At the meeting of the Keynsham Rural District Council held on Dec. 17th a communication was read from the Local Government Board with reference to the payment by the council of fees for bacteriological examinations in suspected cases of diphtheria. It stated that it appeared to the Board that a district council might legally pay such fees, but it would be a matter for the decision of the district auditor. The Board advised the council that in bacteriological examinations a single negative result could not be regarded as decisive and was therefore of far less value than a positive result. One bacteriological examination in a given case of

disease would not invariably yield evidence of the presence of the particular bacillus in the material, and it would be for the medical officer of health to give a caution to this effect to the medical practitioners attending the patients in cases which, though clinically suspicious, did not on a single test furnish sufficient evidence to warrant their being classed bacteriologically as diphtheria.

**DEATH OF A CENTENARIAN.**—Mrs. Agnes Groves of Lymouth died on Dec. 14th, aged 100 years and 14 days.

**NOTIFICATION OF WHOOPING-COUGH.**—At the meeting of the Budleigh Salterton District Council held on Dec. 17th it was decided to omit whooping-cough from their list of diseases to be notified under the Infectious Diseases Notification Act.

**THE NEW HOSPITAL FOR CONSUMPTION AT NORWOOD.**—The foundation-stone of the country branch of the Mount Vernon Hospital for Consumption, Norwood, will be laid in May, 1902, by Princess Christian. Mr. E. Steinkopff has given £500 towards the £3000 required to complete the hospital at Hampstead.

**THE Director-General of the Army Medical Department** has written to Surgeon-Major J. J. de Z. Marshall, 3rd Volunteer Battalion East Surrey Regiment, on behalf of the Secretary of State for War, a letter of thanks for valuable services rendered in medically treating the wives and children of soldiers serving in South Africa and men invalided from the seat of war who have resided in the neighbourhood of Teddington.

**DONATIONS AND REQUESTS TO HOSPITALS.**—The late David McCosh, I.M.S., by his will bequeathed the following amongst other legacies:—Edinburgh Royal Infirmary, £50,000; the Sick Children's Hospital and the Longmore Hospital for Incurables, £100 each.—The Italian Hospital, Queen-square, London, W.C., has been promised anonymously £500 towards the £2500 required for the purpose of opening closed beds and to meet hospital expenses.

**ROYAL COLLEGE OF SURGEONS IN IRELAND.**—THE LATE SIR WILLIAM MAC CORMAC, BART., K.C.B., K.C.V.O., F.R.C.S. Irel.—At a meeting of the Council of the College held on Dec. 19th the following motion was unanimously adopted:—"That the President, Vice-President, and Council desire to convey to Lady MacCormac their profound sympathy with her in her great bereavement and at the same time to give expression to their appreciation of the irreparable loss which the science of surgery has sustained by the death of their distinguished fellow-countryman, her illustrious husband."

**OPENING OF WHITWORTH HALL.**—The expected visit of the Prince of Wales to Owens College in March next to open the Whitworth Hall is looked forward to with great interest. The foundation-stone of the hall was laid by the Duke of Devonshire in June, 1898, and it is the handsomest as well as the latest addition to the buildings of the College. It is to the generosity of the late Mr. R. C. Christie, as one of the legatees of the late Sir Joseph Whitworth, that this addition to the college is due. He devoted upwards of £50,000 to the purpose, only stipulating that the name of Whitworth should be associated with the new buildings. Mr. Christie did not live to see the finish of the work, and thus there is something pathetic in the letter announcing his intention: "Having regard to what I know to have been his most cherished designs in the disposition of his fortune, I believe I shall be acting in accordance therewith, and shall be effectually furthering the cause of higher education in Manchester and neighbourhood, in offering the bulk of this balance to the Owens College for the erection of a hall for the public gatherings of the College and, so far as the amount available will extend, for the completion of the College buildings."

#### BOOKS, ETC., RECEIVED.

**COOK.**—On the 16th inst., at 6, Albert-terrace, Bedford, Lieutenant-Colonel Henry David Cook, I.M.S., retired, in his 55th year. Indian papers please copy.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

## Notes, Short Comments, and Answers to Correspondents.

### MEDICAL AID ASSOCIATIONS AND THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS,—Is it not time that some little common sense was instilled into the General Medical Council and their methods of improvement of the status and pay of general practitioners? By the way, is there on the Council a *bond fide* general practitioner or a member qualified by experience to minister to the general practitioner's wants? Their whole scheme of legislation is destructive instead of being constructive, and the tendency of their work, instead of being to help, is to handicap as seriously as possible the already hard-pressed general practitioner. Take the unqualified assistant. What good did the stringent rule as to his suppression do?—turned adrift, in some cases a man with a practical knowledge of medicine, to make a questionable use of it, or in the case of the more influential practitioner no change has been made—the unqualified man is retained and will be. The Midwives Bill—as if any sensible man wishes to see midwives registered. Are there not enough nurses with an obstetric training, both amateur and professional? What medical man wishes to hand over all his straightforward cases and with them his guineas, to a midwife and retain only the difficult ones—at the same fee, I presume—because they, the difficult ones, are interesting? Interesting, forsooth! The average medical man cares more about the fee than the nature of the confinement. I can at least speak for myself. I do; and the man who says that he does not is either a liar or a fool unless he be independent of his profession for his livelihood. Now they attack the Medical Aid Association. I can tell of many men in good practice who do not scorn to avail themselves of the pecuniary assistance of these societies, and those that do are, in my experience, men who are, fortunately for themselves, too busy with a more lucrative class of work and to whom this attempt at suppression—this sacrifice at the shrine of professional dignity—does not touch in their vital part—the pocket. I could also tell of men, who now have large practices and who are amongst the bitterest opponents of medical aid associations, who, when they started, were only too glad to avail themselves of their help. Why not start with the head of the profession? Why should not a young medical man, poor, struggling, with no means of keeping up his professional knowledge except by frequenting the wards of a large hospital and being patronised by the staffs—why should not he avail himself of this medical aid association work and thereby obtain the practice, advertisement, and experience, and, at the same time, the small and welcome remuneration? And there are many who could say how welcome, if they only had the moral courage, if the consultant may do the same thing for nothing. The consultant has his two or three days a week free under the guise of a large institution and of charity, so why should the general practitioner be struck off the Register if he does the same? Where is the difference? At the same time, the consultant is welcome to his. I for one do not want a free day, but I want the nearest thing obtainable of the same kind, I want the practice and the small remuneration—I want the Medical Aid Association work at present. Who suffers by the abolition? Does the consultant? No. Does the general practitioner in good practice? No; but the young and struggling general practitioner does; and although his superiors are ready and willing to dock his small income in that way they are not equally ready to help him out of the fulness of either their purse or practice. And who gains? Why, of course, being as they—Medical Aid Association cases—usually are, trivial, they do not go to the family medical man and pay their 2s. 6d. or 3s. 6d., but they pay their 1s. or less and support the consulting chemist. Leave the Medical Aid Association alone. Those who do not want it can do without it, and there are plenty who want it and cannot do without it, more especially at first starting but do so afterwards, and why should they, even if they wish, be allowed to kick away the ladder by which they have climbed when it has served its purpose and by which others might follow if not prevented? No! Let the General Medical Council find some method of helping the starting practitioner before they try to take away even the least of his few and paltry supports.

I am, Sirs, yours faithfully,

Harrogate, Dec. 17th, 1901.

HARRY CLOUGH.

### WANTED—A SPA.

To the Editors of THE LANCET.

SIRS,—I am a sufferer from chronic gastritis with septic nasal and buccal cavities accompanied by phosphaturia. Can any of your readers recommend an English spa to suit my case and name a hydropathic or hotel there?

I am, Sirs, yours faithfully,

Nov. 27th, 1901.

ASSAM, L.R.C.P., &c.

### A QUESTIONABLE PUNISHMENT.

To the Editors of THE LANCET.

SIRS,—“What is sauce for the goose is sauce for the gander” is an old yet true adage. If I, who am a lowly L.S.A., prescribe an overdose of strychnine, I—not the dispenser—should be answerable for the consequences. He is not supposed to fathom the rationale of

my prescriptions. Yet if my patient died no one would seek to mitigate my error. Then why should my more distinguished brother escape his censure?

Stockport, Dec. 21st, 1901.

I am, Sirs, yours truly,

J. GOOD.

T. D. has raised some new points, but seems hardly to understand the situation. The practitioners in question were risking penalty from the law, and the General Medical Council could not countenance their action. The law may be wrong, but that is not the Council's fault.

D.—We are of opinion that it will conduce to harmony if the selection of the nurse is left to the matron, but the house committee might well lay down limitations as to wages, experience, age, &c., for the matron's guidance.

Mr. E. H. Stulton writes of a position of affairs that has been called attention to over and over again in our columns.

## Medical Diary for the ensuing Week.

### OPERATIONS.

#### METROPOLITAN HOSPITALS.

**MONDAY (30th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopaedic (2 P.M.), City Orthopaedic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M.).

**TUESDAY (31st).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Free (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

**THURSDAY (2nd).**—RÖNTGEN SOCIETY (20, Hanover-square, W.).—8.30 P.M. Paper:—Mr. C. E. S. Phillips.

**HARVEIAN SOCIETY OF LONDON** (Stafford Rooms, Titchborne-street, Edgware-road, W.).—8.30 P.M. Clinical Cases will be shown by Mr. E. Roughton, Dr. L. Guthrie, Mr. F. Jaffrey, and others.

**FRIDAY (3rd).**—WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith-road, W.).—8.30 P.M. Adjourned Discussion on Mr. T. R. Atkinson's paper on Small-pox, opened by Dr. Dobson with a paper on Glycerinated Calf-Lymph. A proposal will be moved in the following terms: "That the time has come when the Government should exercise control in the manufacture and sale of vaccine lymph and should endeavour to maintain a definite standard of purity and strength."

### LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**FRIDAY (3rd).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Dr. H. Tilley: Clinique. (Throat.)

## EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the

Editorial staff. It is urgently necessary that attention be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

### THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1901, which is completed with the issue of to-day, will be given in the next number of THE LANCET.

### VOLUMES AND CASES.

VOLUMES for the second half of the year 1901 will be ready shortly. Bound in cloth, gilt lettered, price 18s., carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been  
received from—

Subscriptions (which may commence at any time) are payable in advance.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only reads a ready means of finding any notice but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.
